The Engineer's Service to Society

Presidential Address at the A.S.M.E Annual Meeting, 1920, Dealing with the Influence of the Engineer in Constructive Adjustment—Property Rights and Human Rights—Relations Between Employer and Employee

By FRED J. MILLER, CENTER BRIDGE, PA.

IN what turned out to be his inaugural address as President of The Federated American Engineering Societies at its first meeting held in Washington last month, Herbert Hoover said many things that showed very clearly the long distance we have traveled within recent years in our search for industrial peace and industrial efficiency.

Speaking of the part being and to be taken by engineers in this movement and after referring to the grave dangers that may result from contention and warfare between the various economic groups, each seeking to promote its own interests, he said:

> The engineers should be able to take an objective and detached point of view. They do not belong to the associations of either employers, or of labor, of farmers, of merchants, or bankers. Their calling in life is to offer expert service in constructive solution of problems, to the individuals in any of these groups. There is a wider vision of this expert service in giving the group service of engineers to group problems.

Further on he said:

> The employer sometimes overlooks a fundamental fact in connection with organized labor in the United States. This is that the vast majority of its membership and of its direction are individualists in their attitude of mind and in their social outlook; that the expansion of socialist doctrines finds its most fertile area in the ignorance of many workers, and yet the labor organizations, as they stand today, are the greatest bulwark against socialism. On the other hand, some labor leaders overlook the fact that if we are to maintain our high standards of living, our productivity, it can only be in a society in which we maintain the utmost possible initiative on the part of the employer; and further, that in the long run we can only expand the standard of living by the steady increase of production and the creation of more goods for division over the same numbers.
>
> The American Federation of Labor has publicly stated that it desires the support of the engineering skill of the United States in the development of methods for increasing production, and I believe it is the duty of our body to undertake a constructive consideration of these problems and to give assistance, not only to the Federation of Labor but also to the other great economic organizations interested in this problem, such as the employers' associations and the chambers of commerce.

Last March, speaking before the Chamber of Commerce at Boston, he said:

> We must surround employment with assurance of just division of production. We must enlist the interest and confidence of the employees in the business and in business processes. To do these things requires the coöperation of labor itself, and to obtain coöperation we must have intimate organized relationship between employer and employee. They are not to be obtained by benevolence. They can only be obtained by calling the employees to a reciprocal service.

In a story published in one of our magazines last year, the author, Ellen N. La Motte, remarked: "The ability to perceive the obvious is a rare and disconcerting gift."

I wish to call your attention to some obvious things; not only because they are related to, or intimately connected with, the work of the engineer, but also because I believe that engineers in general have more than some others this rare and sometimes disconcerting gift.

It is clear that ours is the professional society of the industries, none of which are or can be carried on without the work of the mechanical engineer, who not only provides the machinery, but also plans the plant and organizes and manages the force of workers.

The engineer must increase the effectiveness of labor, not by driving, by oppression, or suppression—the education and training of the engineer are not needed for that—but by the application of brains in industrial organization and management of men as well as of materials.

A certain deservedly popular railroad president, now retired, used often to say, in his charming after-dinner speeches, that the humblest employee of his road might aspire to its presidency. Thereupon we were regaled by a new broadside of editorials based upon the assumption that the man tamping ties ten hours per day at a wage of $1.10 had no cause for complaint, because not being president of the road at a salary of $50,000 per year was entirely his own fault. We have gotten past that sort of thing because it is clearly seen that if we are to have railroads some one must tamp ties and the welfare of the tie tamper is the concern of the public, especially where the man is an actual or potential citizen and is able not only to express his dissatisfaction in his vote but to pass on to his children his attitude toward the industrial and social organization.

We must face the fact that so far as we can see a large proportion of working people must continue throughout their lives to work, under the direction of others, at tasks intrinsically wearisome and distasteful; and when accompanied by long hours, harsh treatment and wages below the standard of comfortable family maintenance, actually dangerous to our social well-being.

We must remember also that in matters which concern the public welfare and with regard to the general policy to be followed by the nation all must have a voice, including now the women of the nation. It will be a mistake for those who direct industries or who take part in them in any capacity, to assume that the conscience of the nation will not assert itself upon the social effect of misdirected industrial activity.

It is not a misfortune that it does so, annoying as it sometimes appears to be, for it distinctly leads to the maintenance of a proper standard of civilized existence and also tends to protect the fair, enlightened and public-spirited employer from the unfair competition of the other kind of employer.

No one class may safely control in matters of public policy, but all may safely do so, and unless all do, there will be little chance of permanent stability or security.

Our Past-President, Doctor Hollis, has characterized different periods of history as:

The 17th century, the period of exploration
The 18th century, the beginning of religious tolerance
The 19th century, the sowing of the seeds of democracy
The 20th century, the period of crowded invention, and this
The 21th century, the period of adjustment.

If this is correct, as I believe it is substantially, then I hope and believe that the influence of the engineer will be in the direction of constructive adjustment—such an adjustment as will show recognition of the fact that there are both property rights and human rights, and that if human rights are, as Lincoln declared them to be, superior to property rights, then it is still to be remembered, nevertheless, that security of all genuine property rights is a necessary condition of human rights.

The improvement of the human race that is always going on takes many different directions and goes forward in many different fields. The engineer shares with his fellow human beings the results of the efforts of others, and his own peculiar contribution to the cause of human progress must always continue to be an

increasing power to control the forces and modify the materials of Nature for the benefit of mankind. A very important part of this work is what we term the problem of industrial relations, which, it is certain, can never be satisfactorily solved except by the methods of the engineer; and it is equally certain that it can never be settled until settled right; that is to say, not until all concerned—the employed, the employer and the public—are convinced that substantial justice has been secured and is being maintained.

Of course there are and always have been employers who have been fair toward their employees—have been real leaders of men, able to arouse and maintain enthusiastic coöperation. Notable successes have been founded mainly upon this human ability or quality. In too many cases, however, the most profound thought that seems to have been applied to an industrial problem has led to the conclusion that industrial management consists in hiring as cheaply as possible and driving as hard as possible.

The day for that sort of thing is passing and industry generally is beginning to be conducted upon a much higher plane of intelligence. It is being recognized that there is a science of industrial management. Engineers have, so far, developed and formulated it; they must go on with it and conduct the country's industries in accordance with it, recognizing that the old order has passed away. Management of an industrial group is not a matter of brute force, but of intelligent skill, fairly and sympathetically applied with a view to getting the best possible results, not only for the employer, but for the workers and for the public as well.

If research is important in physics and in chemistry it is at least equally important in the domain of industrial science, and when fundamental facts or laws have been made known by such research we must face them; not to do so may mean disaster.

In general, the engineer bases his opinion and his acts upon definitely ascertained and carefully studied facts. We must do the same in our industrial-management problems, and when we do, most of our industrial difficulties disappear.

I have myself known of a large factory, believed by its owners to be well managed, but in which among the employees there was much unrest, much distrust of the management, general bad feeling and lost motion, to be transformed completely under the influence of new management with an enlightened policy and a plan which included no spies nor underhanded methods of any kind, but instead, methods of correcting administrative faults, for helping every employee to be successful with his work and to earn as well as receive high wages.

The better spirit that pervaded the place was remarkable and was reflected not only in greatly improved human relations, but also in greatly reduced labor costs and in the total cost of goods produced, while at the same time the employees earned substantially more money, usually without greater effort than before and sometimes with less effort than before.

We have been hearing a great deal about a falling off in production per man-hour, and there has been a good deal of that. But the fact is that too many of our industrial establishments have been conducted upon the hire, drive, and "fire" plan. I am speaking now of industries in general and of all kinds, not solely of the engineering industries with which we are best acquainted.

In ordinary times when there are more men looking for jobs than there are jobs, that method will answer, though it is never a good method. Men will stand for more or less harsh and unsympathetic treatment when not to do so may mean deprivation for themselves and those dependent upon them.

But in times such as those we have been passing through that method breaks down and the difference between real leaders of men and mere ignorant drivers becomes apparent. There are establishments in which the output per man-hour has not decreased and some in which it has been all along greater than in the prewar period. Some have of course been favored, others hampered by exceptional circumstances, and the necessity of replacing with new help, those who were called for military duty tended strongly to reduce efficiency, in some industries much more than in others. But in general, those who suffered least in that respect were those whose policy was and had been an enlightened and intelligent one rather than the opposite, as indeed we should expect would be the case.

Contact Between Employer and Employee

Too often "results" are demanded by financiers and others who know little or nothing of industrial matters—who are far distant from the locality where the work of production is carried on and ask no questions as to methods, or whether of two local executives producing equal results so far as the books show, one has built up confidence and good will while the other has bred distrust and hatred among the body of employees.

Unfortunately morale and esprit de corps are not itemized on balance sheets, and some of those who are at the head of large manufacturing concerns know little or nothing about manufacturing except balance sheets prepared by men who also know little or nothing of management science and do not suspect that there is any such thing.

The growing number of engineers who stand high in the councils of large manufacturing concerns gives promise of better things in this respect.

In the older and simpler times when the workers very generally came into direct contact with those who were to use what the workers produced, the workers could not forget that they were rendering service to the public; nor could the public forget or overlook that fact. While those who work are today just as truly rendering service to the public, we have between the worker and the consumer whom he serves, a retail merchant, a jobber or wholesaler, the directors of transportation systems, a board of directors with its officers, a superintendent and a foreman.

The foreman is usually the only link in this long chain that the worker knows much about. This would seem to make plain the fact, repeatedly proved by experience, that our foremen should be provided with the machinery, so to speak, of true leadership and then carefully and systematically selected and trained for such leadership. That is a part of the work of the industrial engineer.

It is becoming generally recognized that, whether or not the head of a large industrial corporation will upon request confer with his employees, any group of them, or any freely chosen representative of them, about conditions of employment and of living, is not a question between him and his employees solely, but that the general public may be and often will be interested in the matter. A corporation is created and exists by authority of the people; they may depend upon it for imperative necessities of modern civilized existence; they are responsible for the maintenance of law and order in times of industrial warfare and must usually contribute to the support of workers and others whose means of livelihood are suspended or destroyed by these upheavals. Also they have in most cases provided by means of protective tariffs for the maintenance of prices for the corporation's products higher than the free working of economic laws would permit. The public is thus, in a vital sense, a partner in interest in much of what the corporation does or does not do and we must face the fact that this interest will be increasingly insisted upon unless the industries themselves overcome in a fair and equitable manner the difficulties that now confront them. In accomplishing this means must be found for the coöperation of employer and employee.

The best minds seem to be agreed that this cannot be done by force or suppression, but must be done by intelligent and broad-minded study of what industrial conditions really are and how to improve them; especially how to secure and maintain a spirit of coöperation and of enthusiasm in work, without which no great thing can be accomplished.

As our modern industrial life develops it becomes more and more clear that the broader interests of all of us, whether humble employee or mighty head of an industrial organization, are interwoven and inseparable. Formerly it seemed clear that the public was interested in industrial strife only where public service functions might be disturbed or suspended; but events have made it clear that, from the standpoint of public health, public education, service to the country in time of war or other emergencies, and of the general well-being of society, present and future, industrial strife concerns everybody; and there is a growing public sentiment according to which any industrial executive who refuses to confer with his employees, with their freely chosen representative, or with the representatives of any group of them, about the condi-

if not the probability, that legislation as an expression of this public sentiment may follow.

Such a conference, properly and fairly conducted, will at least enable each side to know just where the other stands and why. Often this is sufficient to point out a clear way to a satisfactory adjustment. And a conference about business matters of mutual interest is not the handing over of one's business to employees or their representatives. Even if no concessions are or can be made, such a conference is almost sure to promote mutual understanding and good feeling; and I speak from personal knowledge and experience when I say that it may and often has prevented what might have been serious disturbances.

Such conferences however, in order to be effective for good, must be as friendly and courteous as other ordinary business conferences between men whose duty it is to coöperate for a common purpose and for mutual advantage; men who, in other words, desire to, or must, maintain a decent friendly relation, not an antagonistic or a patriarchal relation.

If it be understood that any matter which any employee, or any group of employees, wishes to have adjusted can be brought to the attention of the management, either by an individual, by a committee of employees freely chosen by the men for that purpose, or by any other agency whatever that seems advisable to the workers themselves, acting freely and without coercion, and that such a matter will be regarded as a legitimate business affair and especially that no prejudice will arise against any member of such committee for having thus served his fellow-employees, very much misunderstanding will be avoided. If this plan is followed there will be no need for spies among the employees, spies being themselves not preventives of trouble and misunderstanding but promoters of them, often deliberately and intentionally so.

If the conditions of employment are fair and right, if there are few or no substantial reasons for dissatisfaction, if the channels of communication between owner and workers are kept free and open, agitators and trouble makers will seldom if ever make much headway.

Sometimes, however, under present conditions, a strike may be unavoidable. When it takes place if the management will make it plain to the men that they are not blamed for having the ambition to improve their condition; if there are no bitter denunciations; if there are no newspaper interviews condemning the men as being mentally incompetent or intentionally unfair and unreasonable; if it is regarded simply as a human error, or as a fever which will soon pass away; and that when it does, such of the strikers as have been decent and orderly and can be reemployed will be welcomed back, singly or in groups; if foremen and superintendents who have known the men they now find acting as pickets and have been in the habit of greeting in friendliness, will continue to do so; a satisfactory settlement will be much more easily, more quickly, and more surely reached than by the usual plan of recrimination and bitter denunciation.

This more advanced attitude must not be assumed for the purpose, however, but must be the reflection of a genuine feeling of sympathy and of tolerance. It is human nature for a man to be much more influenced by the opinion and advice of one who is friendly and sympathetic than of one who is contemptuous, harsh, or filled with hatred.

In commending this plan of procedure, which I realize may seem to many employers impracticable or impossible, I speak, nevertheless, upon the basis of experience, not only of my own, but of that of others, in large as well as smaller organizations, and it is not advanced as being in the interest of employees only, but of employers as well.

Foremen Trained for Leadership

Particularly do foremen usually need to be trained, or educated, if you please, to know how to treat men in order to get their enthusiastic coöperation and their best efforts. The foreman being ordinarily the only man representing an employer with whom the worker comes into contact, the "local color," so to speak, of are on record, for instance, in which the good intentions of an employer in providing rest rooms for women employees were, unknown to the employer, set at naught by a foreman who cared nothing for rest rooms, but believed in driving women so long as they could stand at their machines.

Too little attention has been given to this and foremen need to be trained for leadership and led to understand that most workmen, if properly handled, are as ambitious to "make good" as they are themselves, and that by sympathetic leadership and teaching where needed, excellent workmen can often be developed from what at first may seem like very unpromising material. This is not mere theory or idealism, but is based upon wide observation and a very considerable personal experience in establishments run upon all sort of plans, from very good to very bad.

Difficulties with men are often due to causes that are obscure. A group of workmen who resisted a perfectly fair and mutually advantageous proposition pertaining to their work, were not understood until it was finally discovered that a thoughtless and ruthless "comptroller" recently placed in power, had, merely for his own convenience, arbitrarily made a change in their pay day which had seriously inconvenienced them. He had no more thought of consulting them about it or consulting the superintendent under whom they worked, than as though they were so many soldiers, compelled to obey without question any regulations made concerning them. By this they were for the time being convinced that the company cared nothing for their interests and, reciprocally, they cared nothing for the company's interests and were suspicious of any proposition made to them.

I am not, of course, to be understood as saying that they were right in that, but we are dealing with human nature and must take men as they are and make the best of them. Workmen are, after all, about the same as other people, will respond to given treatment in about the same way, and act about the same under given conditions. When we fully realize this we shall be on the right road to an understanding of them and of how to get along with them.

Successful industrial management has been declared to be, more than anything else, a "state of mind." The various systems we are now hearing so much about vary greatly in their capacity to help in arriving at good conditions, but under the best of them there must be a foundation consisting of a determination to be fair, considerate and entirely candid and aboveboard, or they will be of little use.

If I seem to stress unduly the duties and responsibilities of engineers and employers in these troublous times, it is of course not because I believe the workers to be faultless, but in the daily and in the trade press their shortcomings have been abundantly set forth and the present pressing problem is as to what the engineer and the employer may and ought to do to bring about a better understanding. That can be done, but not by dwelling upon old grievances or by calling hard names. There must be mutual forbearance, mutual understanding, and a general recognition of the fact that men who are to be of any use to society or to the industries must have their personal ambitions, and in order to have them must see some chance of attaining them.

We are hearing constantly more about service as constituting the only just claim to rewards. Certainly the engineer need not fear comparison with others on that score. Yet there are those who, with the best intentions I am sure, charge a large share of our industrial and social difficulties to features of modern industry that have been created and are maintained by the work of the engineer.

Especially do they charge that doing things by machinery instead of by hand, and the multiplication of large manufacturing establishments in which the work is minutely divided, have had a bad effect—have, indeed, made men and women slaves of the machine.

I think we may claim that there is a misapprehension about this and that machinery and large industrial establishments do not nor can they by themselves enslave or oppress human beings.

It is easily demonstrated by reason and by human experience that division of labor, machinery for increasing man's productive capacity and the use of capital in production all tend, by themselves considered, to help the worker—to release him from burdensome tasks and from the necessity for working too hard or too many hours per day for too little money.

Two Kinds of Monopoly

But certain monopolies may and do have the opposite and injurious effects referred to; especially monopoly of the earth's resources and the holding of such resources idle and beyond the reach of labor and capital that might otherwise be applied to them for the satisfaction of the wants of mankind.

And our tax system acts as though it were especially designed to promote this result, to discourage industry of all kinds and to encourage the holding idle of the earth's resources for higher prices to be brought about by pressure of population and the enterprise and labor of others.

Many a manufacturer has been hampered in making enlargements of his plant by the high prices of vacant and idle land needed for that purpose; said high prices having been actually created by the activities of himself and his employees and in no degree by those who had been holding the land idle.

Fourteen years ago our Society held its Spring Meeting in Chattanooga and visited a water-power development in the Tennessee River, near there. At that time the large dam was about half-finished and I was told by a prominent member of this Society, himself a manufacturer, that already in anticipation of the coming cheap power, the owners of factory sites on which it might be utilized had doubled or trebled the prices at which they were holding them.

We hear much of the blessings to humanity of the cheap water power that may be developed in large quantities from our streams. As a matter of fact, it will be found that in nearly every case where water-power rates are substantially less than the cost of steam power, the total cost of the water power is nevertheless about the same as for steam; for the owner of available land on which to build factories and who, as such, has rendered no service of any kind either in producing power or in any other way, pockets the difference in prime cost—not the engineer, the manufacturer, nor the consumer of the goods produced.

Moreover, while as a general thing the manufacturer whose efforts and enterprise build up these values is taxed heavily for doing it, the vacant-land owner escapes with nominal taxation on the ground that his property is non-productive, if you please.

I mention these things, not because it is the engineer's special province to deal with them, but it is at least as much his business as that of any other citizen and it has a direct and vital effect upon his work and his opportunities for employment, or for going into business.

If it is the engineer's business to render service, then it is equally his duty to see to it that so far as possible all others do the same, and he has only to look about him to see that very many do not render service, yet are "clothed in purple and fine linen." The cure is not to take away their purple and fine linen, but simply to see to it that their having it is not by reason of their being able to restrict the opportunities of others for access to Nature's storehouse of raw materials and to work for the general welfare.

It is to be hoped that the day will soon come when every able-bodied and able-minded man will find it necessary to render actual service for what he receives and in fair proportion to what he receives. When that has been accomplished we need not concern ourselves overmuch about the way in which he spends his money. It will be clearly and of right his money, and the opportunities for spending it in such a way as to injure society will be much less than now.

That engineers are giving much more thought to these matters than formerly and are perceiving their important bearing upon the work and life of the engineer and all workers, is indicated by the fact that the President of the American Institute of Electrical Engineers, in his presidential address last year, discussed them, and the President of the American Society of Civil Engineers, the well-known Chief of the Reclamation Service, in his presidential address also discussed them; and we three, at least, are in agreement concerning them and their commanding importance, particularly in their effect upon the work of the engineer in whatever field of endeavor he may be engaged.

Of course an engineer or a manufacturer may be also the possessor of special privilege or a monopoly of one kind or another; but comparatively few of them really are, and where an engineer has acquired enough property to be called even moderately well off in these days of colossal fortunes, it will be found that his success in this is based upon the value of service which he has contributed to the general welfare, and those who envy such a man or who would limit his activities or his prosperity are very few and have practically no effective influence.

We can think of some engineers who have acquired what, until recently at least, would have been considered wealth. But they have usually done this in strictly competitive lines of business, engaged in by others, and open to all comers upon equal terms.

Compare the case of Corliss, for instance, and his early practice of selling his new improved engine upon the basis of a stated share of the saving in fuel for a limited time, with those usually absentee owners of the anthracite coal fields of Pennsylvania who create no coal, dig nor transport any coal, do nothing about coal except to own the ground in which it was placed by Nature long ages ago, "for the benefit of mankind," as we are fond of saying. Some of these owners are reported to have been recently doubling and more than doubling the royalties they collect for the mere privilege of employing engineers and miners and using machinery in the production of coal; the state of Pennsylvania helping them to retain their grip upon the coal supply by taxing their as yet unused coal lands at ridiculously low valuations as "unproductive farm lands," if you please; while real farmers in that state are taxed heavily not only upon their lands but upon everything else that can be found in their possession.

Herein is the backbone of the anthracite monopoly which is a grievous burden upon industries and upon coal users, and obstructs not only the production of coal but of all manufactured things in the production of which coal is a prime necessity. Being a citizen and a taxpayer in the state of Pennsylvania gives me the right, if nothing else does, to criticise its unenlightened and grossly unjust taxing system.

There are those, however, who will say that Corliss made his money by the possession of a monopoly, because his engine improvements were patented. But engineers especially need to clearly perceive the vital difference between such a monopoly as Corliss enjoyed and those monopolies of the earth's resources to which I have referred. Corliss had, for a limited time only, a monopoly of that which he had himself created, and any one who chose to do so went on using the plain slide-valve engine after the Corliss appeared, and all surely would have done so had not the terms offered by Corliss for the use of his improved engine been advantageous for the purchaser as well as for Corliss. In other words, the benefits arising from the improvements of Corliss were shared, first, by the purchaser of the engine, then by users of power, and finally by everybody.

Nearly always the same is true of any invention. It will not come into use unless purchasers of it share the benefits of what, before the invention, did not exist. Have we equal freedom of choice in the matter of fuel, not invented by man but created by Nature and an indispensable necessity of modern civilized existence?

Some thirty years ago a member of this Society invented a steam-engine governor from which he received a fortune in royalties based upon a certain charge per horsepower of engines to which it was applied. It is safe to say that that governor was never applied to one engine without benefiting both the engine builder and its purchaser by an amount far exceeding what was paid for its use. We are playing directly into the hands of those who advocate the socialization of all property and of all human activities when we for one moment admit that the inventor of any such thing is to be classed with those who monopolize that which is the common heritage of all of us—that which no man created and without which human existence cannot be maintained.

It would of course be wrong to condemn individuals who simply take advantage of a system that has long been tolerated by their

(Continued on page 8)

cotton-finishing plants in which, under ordinary conditions, the steam required for processing is greater than that for power development. The generation of power and of steam and the applications to the driving of process machinery are traced briefly from the boilers to the motor applications. Charts are presented showing the steam consumption and the proportion of the exhaust steam converted into work and available at the exhaust for different types of prime movers. Illustrations of typical drives are included.

In the finishing processes in the textile industry, such as bleaching dyeing, mercerizing, printing, calendering, etc., the quantity of steam required for processing and for the heating of manufacturing space may be from two to four times that required for power.

Opinion as to the lowest working steam pressure for process work consistent with steady output and a minimum production of "seconds," is almost as varied as the number of plants. It has been found, however, that with ample heat transfer surface, pressures of from 10 to 15 lb. gage, with an average of 12 lb., will take care of fully 80 per cent of the requirements in finishing.

It follows, therefore, that all power may be generated as a by-product by utilizing engines or turbines as reducing valves. Steam at boiler pressure is thus reduced to the low pressure of the exhaust line without thermal loss other than the heat converted into work and, in case of reciprocating engines, the loss in cylinder condensation.

From the economic standpoint power cost will be merely the fuel equivalent of conversion and condensation, labor and material

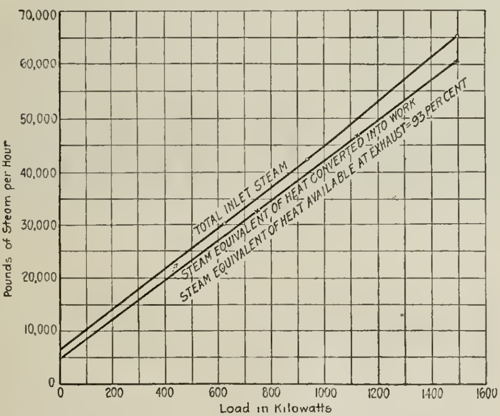

Fig. 1 Steam Consumption and Available Exhaust from a 1500-kw. Non-Condensing Turbo-Generator

Steam pressure at throttle, 175 lb. per sq. in.; back pressure at exhaust, 12 lb per sq. in.; steam flow at full load per hour, 65,000 lb.; equivalent steam available at exhaust, per hour, 60,600 lb.; inlet steam available at exhaust, 93 per cent.

costs in attendance upon and maintenance of equipment, and fixed charges on power-plant machinery. Under these circumstances purchased power can seldom compete with self-generation, provided the installation be large enough to keep the overheads and operating labor costs to a low figure per kilowatt-hour of output.

Boilers

For obvious reasons water-tube boilers are coming into more points of superiority over horizontal or vertical fire-tube boilers which manifest themselves in central station use apply in the selection of boilers for a finishing plant. The working steam pressure should range from 150 to 200 lb., the higher figure being preferable where its use does not add unduly to the first cost of boilers. A moderate degree of superheat is desirable, although not essential. Superheat reduces condensation in steam lines and results in somewhat better economy of engines or turbines, but there may be objections on account of the superheaters and their maintenance.

Among the items of minor equipment which are becoming increasingly popular may be mentioned soot blowers and reliable feedwater regulators.

Fuel and Firing Devices

The kind of fuel used is intimately associated with its method of burning. The use of steam sizes of anthracite, except where

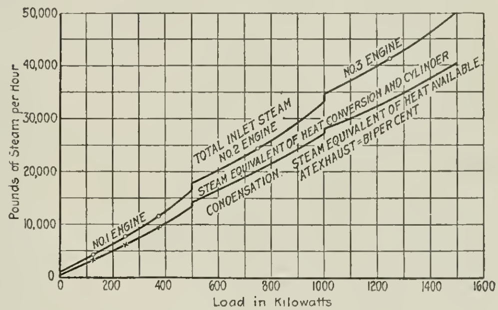

Fig. 2 Steam Consumption and Available Exhaust from Three 500-kw. Non-Condensing Engine Generators

Steam pressure at throttle; 175 lb. per sq. in.; back pressure at exhaust, 12 lb per sq in.; steam flow at full load, per hour, 50,000 lb.; equivalent steam available at exhaust per hour, 40,600 lb.; inlet steam available at exhaust, 81 per cent

mixed with bituminous coal, is not increasing. The market is restricted, and few types of stokers for this fuel have been developed. High boiler ratings easily reached with bituminous coal cannot be duplicated with anthracite; hence the installed boiler capacity and the first cost of boiler plant must be greater than with soft coal. Increasing fuel costs, higher freight rates and labor advance all work under normal market conditions toward the reduction in consumption of the lower grades of anthracite, particularly at points remote from the coal fields.

As in all other industries, bituminous coal leads in the proportion of fuel utilized by finishing plants. The newer installations for soft coal have underfeed stokers, of which there are now several reliable types on the market. Where the cost of large brick or steel chimneys is prohibitive, induced-draft fans may be installed, and this apparatus is always provided with economizer installations.

Fuel oil is the ideal fuel, but high price and possibility of shortage during times of emergency have combined to restrict its use. There are many advantages and economies in its use, and very recently there has been evidence that the large oil producers are entering the field to secure new business. Quick steaming, cleanliness and reduction in labor are the foremost economics, but no large plant should go to oil fuel without providing means for quickly converting a portion of its capacity to coal burning in case of acute and prolonged shortage of oil.

The use of powdered coal as a boiler fuel is just beginning to emerge from the experimental stage. Under favorable conditions the efficiency of combustion will be high, but offsetting this are such points as: liability to dust explosion; cost of drying and

[1] M. E., Day Zimmermann, Inc., Jun. Mem.Am.Soc.M.E.

Abstract of a paper presented at the Annual Meeting, New York, December 1920, of The American Society of Mechanical Engineers. All papers are subject to revision.

grinding; nuisance from fine ash which will be deposited on adjacent property; and high brickwork and refractory maintenance.

Prime Movers

The selection of primary drive is a matter which will depend to an extent on the size of the plant and the schedule of operation. In certain districts water power is still available during a considerable portion of the year, and this power is usually utilized by the mills as a part of privileges and grants dating back to the original acquisition of the mill property.

The water-power companies will likewise sell surplus water power under contract conditions, but the charges for such excess

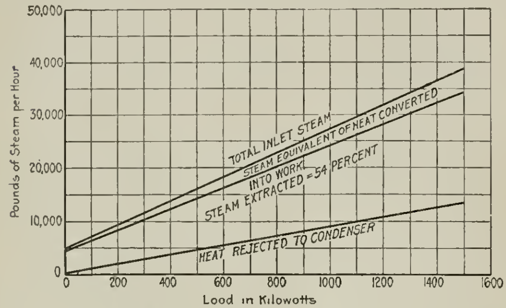

Fig. 3 Steam Consumption and Available Exhaust from 1500-kw. Extraction Turbo-Generator

Steam pressure at throttle, 175 lb. per sq. in.; extraction pressure, 12 lb. per sq. n.; vacuum in condenser, 28 in.; steam flow at full load, per hour, 39,000 lb.; steam extracted at full load, per hour, 27,000 lb.; inlet steam extracted, 69 per cent.

power will likely be in excess of rates for purchased power. This is due principally to the fact that individual mills have small wheels of low efficiency, and the power company, where itself engaged in the hydroelectric business, can develop a horsepower hour through its larger and more efficient machinery on less water than the

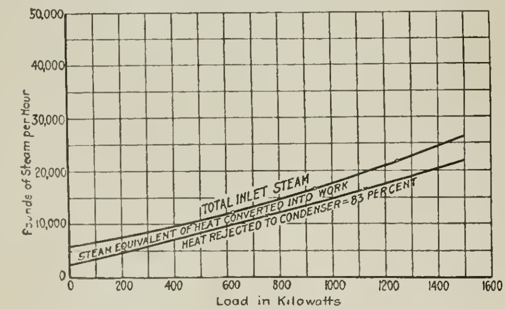

Fig. 4 Steam Consumption of a 1500-kw. Condensing Turbo-Generator

Steam pressure at throttle, 175 lb. per sq. in ; vacuum at exhaust, 28 in.; steam flow at full load per hour, 26,400 lb.; inlet steam rejected in circulating water, 83 per cent.

individual mill. Likewise conditions of load factor and diversity, together with control of storage water, generally put the power company in a more favorable position to utilize the water than to sell it.

Where water-power privileges have been acquired in terms of horsepower without time limit as to use, the individual mill can generally afford to continue any existing development up to its original privileges, particularly if some departments requiring power in excess of process steam are likely at times to operate when the rest of the plant is idle. Water-power privileges form a convenient means of developing power for night lighting and for the overtime operation of mechanical departments.

Naturally the available water power is subject to considerable seasonable variation, and a plant desiring continuity of operation must of necessity have sufficient steam-power stand-by to take care of its requirements under low-water conditions. The chances for duplication in investment are therefore obvious, so that the development of power from water should in every case be subject to careful analysis.

Steam power in the smaller mills may be developed in economical engines, but for plants requiring any considerable amounts of power the turbine drive from all points of view is preferable. Any steam engine, no matter how efficient, is subject to cylinder condensation, which represents a dead loss, whereas a turbine will extract from the steam only such energy as is converted into work, retaining the remainder of the latent and sensible heat in the exhaust steam.

This point is worth emphasizing, because it may happen that a certain type of steam engine has an actual water rate per unit of output lower than the same size of turbine. However, the net heat available for processing will always be greater with the turbine.

There is a field of application for the bleeder type of turbine in which steam may be extracted from an intermediate stage for processing or for building-heating requirements. The excess

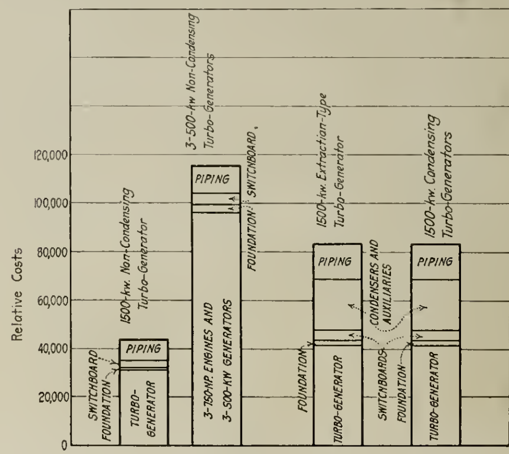

Fig. 5 Relative Installation Costs of Four Different Types of Prime Movers

steam to make up power demand passes to a condenser. The latent heat in this condensed steam may in part be recovered by utilizing circulating water for processing and for make-up boiler feedwater. There will, however, be at all times an unavoidable loss of heat rejected at condenser outlet.

Figs. 1 to 4 show for prime movers of four different types the relative steam consumption per unit of output and the relative heat consumption under conditions where exhaust steam can be fully utilized at all seasons of the year. Assuming in each case that the primary drive is connected to an electric generator, the relative costs, based on a 1500-kw. size, will be approximately as shown in Fig. 5.

Electric Drive

Except in smaller mills where belt drive may be used in connection with a steam engine, the tendency is now entirely toward electrification, both by groups and by individual machines.

The electrical characteristics of generators and motors must be determined after a study of the local requirements for variable speed as against constant-speed drives. In certain instances the selection will be influenced by the amount of electrical equipment already installed in the mill and the power characteristics of the local public utility on whom it may be desired to depend for standby service.

The three main subdivisions of power applications to finishing plants are:

moderate speed variation not in excess of 2 to 1 to accommodate variation in fabric and process. This includes certain forms of mangles and cans, sheet ranges, starch mangles, mercerizers, khaki, sulphur and indigo dyeing machines and steamers.

c Such power as is required to drive process machinery where the demands for variation in speed are in excess of 2 to 1. This class of equipment includes long tenters, aging boxes and multi-color printing machines.

For variations in speed in excess of 2 to 1, the direct-current motor occupies the leading position, unless it be desired to resort to some form of mechanical speed-changing device.

In the class of finishing plants considered, the operations of tentering and printing will frequently require speed ratios outside the range of commercial forms of alternating-current motors. Hence the proportion of power consumed by motors driving tenters and printing machines to the entire mill requirements, is an important factor in deciding whether the entire electrification shall be direct current, or whether a combination of alternating and direct current be applied. A suitable direct-current voltage is from 230 to 250 volts.

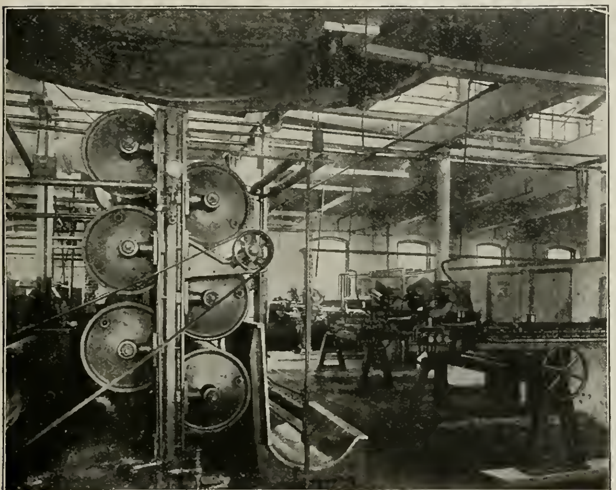

Fig. 6 Installation of Compensating Roll for Synchronizing Two Variable-Speed D.C. Motors

In the larger mill projects the electrical characteristics of generators are generally 3-phase, 60-cycle, with voltages varying according to the choice of the designer and his method of solving the power problem.

The voltages in use are 220, 440, 550 and 2200, the two intermediates being the most popular. The lowest voltage calls for large sizes of conductors and conduits, and the highest cannot be used directly on all mill motors, hence transformers for stepping down to motor voltage must be installed. In such a development direct current may be obtained from rotary converters or motor-generator sets. Although the rotary converter has a higher efficiency and may occupy less floor space than the motor-generator set, the use of the latter is preferable because of its ability in effecting power-factor correction.

Modern alternating-current generators are designed on a basis of maximum current output, hence in such finishing plants as have a large proportion of inductive motor load it may be well to specify a load power factor of 70 per cent or 75 per cent when selecting generators, rather than the more usual 80 per cent used in central-station practice

will have a lower water rate for the off-peak load.

Another method successfully applied is to provide some excess capacity in the steam exciter and by means of a selector switch transfer the lighting load from the normal supply of three-wire 100-volt alternating current to two-wire 110-volt direct current. Likewise the shops may be equipped with a 110-volt direct-current motor taking its power from the turbo-exciter and driving the shops when the manufacturing departments are idle.

Where the size of the equipment justifies the expense, generator coolers should be installed in connection with high-speed alternating-current turbo-generators. These generator air washers not only permit of high capacity of the generators during extremely warm weather, but likewise remove coal and ash dust, lint and any other foreign matter whose presence might damage the generator windings.

Motor Application

Constant-speed groups or individual drives are best operated by induction motors controlled by motor-starting switches convenient to the operator and protected against injury by overload and low-voltage trips.

For constant-speed drives having heavy starting duty it may be necessary to use slip-ring motors with drum controllers and with resistances in the controller circuit for starting duty only. A safety or oil switch should be provided in the primary circuit.

Another group of drives falls in the class where the requirements of the process are met by a speed reduction of two to one, or where the lowest speed needed at any time will be 50 per cent of the maximum speed. It is not always necessary under these conditions to resort to the direct-current motor, since a slip-ring motor with secondary resistance banks designed for continuous running at any point of the controller has been found suitable for mangles, cans, open tenters and sheet ranges.

The control equipment consists of a drum controller and resistance for the secondary circuit. The incoming feeder should be protected by an oil switch with overload and low-voltage releases.

It should be borne in mind in applying slip-ring motors for variable speed that, except for the limitation of maximum speed imposed by the frequency of the alternating current, a slip-ring motor has speed and electrical characteristics very similar to the series type of direct-current motor. Consequently variations in load arising from such adjustments as the set on rolls or the friction of cloth over cans and rollers will produce variations in speed without any change of controller position.

The applications of variable speed with higher ratios by means of direct-current motors opens up a wide field in the selection of control equipments. Various manufacturers have developed outfits to suit local conditions and the ideas of the designer. These controls vary all the way from the simple faceplate rheostat for varying the field strength of a shunt-wound direct-current motor to the more elaborate push-button control contactor panels.

A form of safety device which should never be omitted is some form of push-button or snap-switch release whereby the back tender on printing machines or tenters may from his position instantly shut down the entire equipment.

It is usually convenient to use two motors for driving long tenters, one driving the tenter equipment proper and the other operating the mangle and cans. In order to preserve proper synchronism between the two motors, a compensating equipment such as is illustrated in Fig. 6 may be applied.

Since in the raw materials utilized in finishing plants steam and power rank second only to gray goods and drugs, the necessity for measuring the power and steam consumption of all departments

is obvious. This can be accomplished by the simple application of integrating wattmeters to power feeders and of flow meters to steam lines. The number of electric and steam meters need not be excessive and their cost will soon be returned in the form of better knowledge on the part of the executive as to plant conditions, and in the ability to locate immediately and check wastes and losses. An actual steam distribution is shown in Fig. 7 for both the heating and non-heating seasons.

In some cases there may be a tendency toward thermal unbalance occurring during periods of low production in the non-heating season, or during periods of the working day when the power load is building up more rapidly than the process steam consumption. Any loss of this kind may be checked readily by the installation of a storage heater, in which the heat-transfer surface is proportioned in accordance with the rate of discharge of exhaust steam, and the volumetric or storage capacity in accordance with the duration of the period of unbalance and the

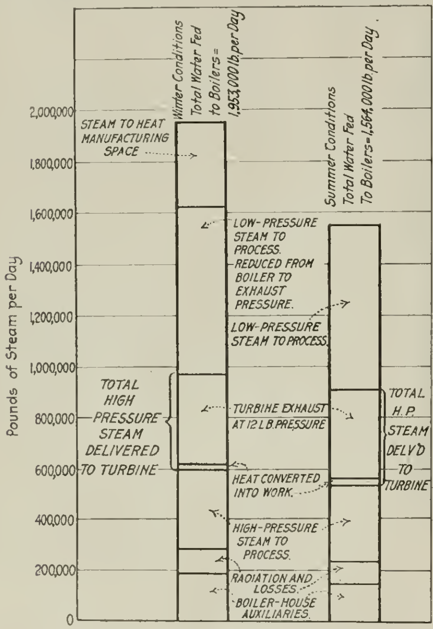

Fig. 7 Steam Distribution (Heating and Non-Heating Seasons) for Finishing Plant with Correct Heat Balance

X: Total high-pressure steam delivered to turbine.

heat to be absorbed in that period. This hot water can be drawn upon for washing or for whatever purpose hot water is required in the process.

A general plan of power application based on a complete heat balance such as has been described in this paper will lead to very substantial economies in fuel, labor and maintenance costs in the power department over the more general use of engines for group or individual drive. Particularly at this time, because of advancing freight rates, scarcity of fuel, high prices prevailing and unsatisfactory transportation conditions, have fuel costs and power economies assumed national significance. Indeed, the Government has recognized the prime importance of this problem in its relation to the conservation of natural resources through the superpower survey being conducted by the Department of Interior.

THE ENGINEER'S SERVICE TO SOCIETY

(Continued from page 4)

fellow-citizens, and is generally looked upon as respectable and proper. It is not individuals but the system that is wrong, and wrong because it permits and even entices men to take steps to secure large rewards without doing anything of real value in return for them; particularly to make themselves a heavy burden upon the industries which the engineer is trying to develop and upon which he depends for his opportunities to render service.

All clear thinkers, I believe, support and will maintain the just rights of property; but it is becoming clearer every day that a necessary condition for safe-guarding property rights is, first and above all, the safe-guarding of human rights. In fact, security of property rights rests, finally, upon the maintenance of human rights.

It is not true that "the world owes every man a living," but the world does owe every man an exactly equal opportunity to earn a living.

And let us not be deceived by the newly invented factor of production called "ability," which, it is asserted, rests somehow upon an economic basis different from that of labor. Labor, in the broad sense—the economic sense—is any kind of useful endeavor, mental or manual. There are only three factors in production of wealth: land or Nature's resources; labor, mental or physical; and capital. The invention of so-called "ability" as a fourth factor has no basis in reason or experience and its only function is to confuse our reasoning about industrial and economic problems and to bring us to erroneous conclusions concerning them. Especially has it been invoked in attempts to justify exorbitant gains by those who rendered no service in return and were often mere gamblers. A burglar or a pickpocket may exercise ability in his profession, and even the right kind of ability is of no use unless exercised, and then it is labor.

If it is true that any considerable portion of our American workers are being led astray by ultra-radical teachings, then such teachings may be most effectively combated by such teaching as the engineer is in a position to give. But it will not answer to simply assert that there is nothing the matter and that we should all be content with things as they are, or as they were in a time now past and gone. There must be, in such teaching, evidence of a real understanding of what conditions really are and of a sympathetic attitude toward any reasonable and fair ambition to improve them.

It must be shown, as it easily can be, that profits, in normal times and in competitive lines of business and manufacturing, are usually and on the average not greater than they need to be to attract to them capital and men capable of carrying them on; and that business men and manufacturers as well as workers, often suffer from the power of special privilege and inadequately regulated monopolies.

The fact is that our economic and social science has not kept pace with the work of the engineer; for he, in his own work, is by temperament and training an innovator. He lives to persuade other people to do new things, or to do old things in entirely new ways. This being so, it would seem to be logical that he himself should at least maintain a sufficiently open mind to avoid resisting a new thing concerning which he has not cared to, or has had no opportunity to, investigate.

Whether it be a new idea in industrial management; revision of our tax system so as to remove burdens from beneficial activities and to discourage monopolies; a League of Nations to preserve the peace of the world, so that the results of the work of the world can be wholly useful instead of largely wasteful, destructive and pernicious; we engineers, especially, ought not to remain bound by mere custom, which, as Guizot said:

". . . .contracts our ideas with the circle it has traced for us; it governs by the terror it inspires for any new and untried condition; it makes us believe the walls of the prison within which we are inclosed to be the boundary of the world, and beyond all is undefined, confusion, chaos, where, it makes us feel, we should not have air to breathe."

Customs and usages have their places and their values, but when new problems present themselves we must not shrink from the contemplation of what are, or may seem to be, new remedies, so long as they are founded upon established principles of justice and fair dealing.

form of the thread on the work, or in other words, the form of the tooth on the hob is not reproduced on the threaded part. The present paper is the result of a mathematical investigation of this subject and points out the corrections in the form of thread-milling hobs which can be readily made and also produce threads sufficiently correct as to form for all practical purposes. The profile of the thread cut with a hob is a combination of two distinct curves. First, a small fillet is formed at the root of the thread which is the path of the outside corner of the hob. No correction in the form of the hob is possible to correct this point. Second, the larger part of the flank of the thread consists of a slightly curved profile which is formed by the overlapping paths of the infinite number of cutting points which form the cutting edge of the hob. Mathematically, a curved correction can be applied to the form of the hob which will correct this profile entirely. Practically, a straight-line correction can be applied which is almost exact, as the amount of the actual curvature on the flanks of the thread is seldom greater than one-tenth of a thousandth part of one inch. The greater the angle of helix of the thread, the greater the amount of correction necessary. The complete paper deals with both externally and internally threaded parts, but in the present abstract only externally threaded parts are considered. The general conditions of side-cutting are identical, however, in both cases.

When a thread is chased in a lathe and the cutting tool has proper clearance and is set so that the plane of the cutting edges contains the axis of the thread, the exact form of the tool will be duplicated on the work. Assuming that the thread is completed, if the tool in its cutting position is brought into contact with the flanks of the thread, it will have a line bearing only. If sufficient clearance can be provided on the tool, this holds true regardless of the pitch of the thread, the angle of the flanks, or its diameter.

When a thread is hobbed, however, the axis of the hob being parallel to the axis of the thread, the path of any one cutting point is a circle, and this circle will interfere with the helix of the thread to an amount depending upon the pitch of the thread, the angle of the flanks, and the diameters of both hob and thread.

It is assumed in this discussion that the cutting teeth of the hob are backed off sufficiently to prevent any dragging of the relieved portion of the tool on the work. The interference between the cutting edge of the hob and the helix of the thread therefore results in the removal of additional metal, thus distorting the form of the thread. The amount of this distortion varies as the values of any of the following factors change: the pitch of the thread, the form of the thread, the diameter of the work, and the diameter of the hob.

It will be shown that correction for some of this distortion inevitable with this method of manufacture is impossible. The amount of this distortion, however, can be reduced in many cases by the proper relation between the diameters of work and hob. It will also be shown that most of the distortion can be corrected by a suitable alteration in the form of the cutting tool.

The Hobbing of Screws

In Fig. 1, which shows a diagram of a hob and screws, let

- R = radius of any cutting point on the hob
- r = radius of deepest point on work touched by R
- N = number of threads per inch
- A = angle of rotation of hob
- B = angle of point of contact of R at angle A
- C = $^1/_2$ included angle of thread
- r' = radius of point of contact of R on work.

Formulas will first be derived to show the interference between the path of any cutting point on the hob and the flanks of the point R from the deepest point on the work touched by R will be designated as y. In other words,

$$y = r' - r \qquad [1]$$

The longitudinal (or axial) distance R of the cutting point from the flank of the theoretical thread will be designated by x. A plus value of x will indicate a clearance, while a minus value will indicate an interference or side-cutting.

In order to determine the value of y the triangle shown in heavy lines in Fig. 1 must be solved. The known factors will be taken as r, R, and B. We first have

$$\frac{(R + r) \sin B}{R} = \sin 180° - (A + B)$$

$$\sin 180° - (A + B) = \sin (A + B)$$

$$\frac{(R + r) \sin B}{R} = \sin (A + B) \qquad [2]$$

From this equation we determine the value of A. Solving the triangle for r', we have

$$r' = \frac{R \sin A}{\sin B} \qquad [3]$$

and when the value of r' is determined, the value of y is established from Equation [1].

As the hob revolves away from the common center line of the

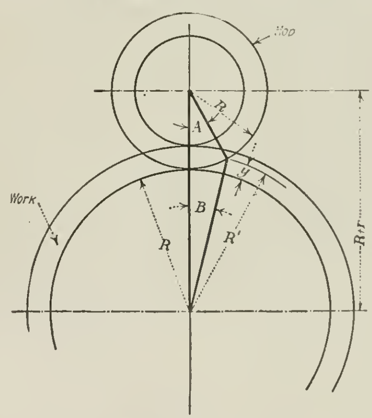

Fig. 1 Diagram of Hob and External Screw

hob and work, the cutting points on one side of the tooth of the hob, due to the helix of the thread, will have a clearance with the flank of the thread, while the cutting points on the other side of the tooth of the hob will develop an interference. But the side of the hob which clears the helix as the cutting point revolves away from the common center line will interfere as the cutting points approach to the common center line, and the nature and extent of this interference will be symmetrical and equal on both flanks of the thread as long as the form of the thread is symmetrical.

The amount of interference depends upon the value of B and the pitch of the thread, or number of threads per inch, N. Thus

$$\text{Interference Due to Helix} = \frac{B}{360N} \qquad [4]$$

If the included angle of the flanks of the thread is greater than zero (which is the case for all but square threads), as the cutting point of the side of the cutting tooth departs from the common center line of the hob and work a clearance develops between the cutting point on the hob and the flanks of the thread. The amount of this clearance depends upon the value of y and the included angle of the thread, and referring to Fig. 2 it will be seen

[1] Engr. of Standards, Niles-Bement-Pond Co., and Pratt & Whitney Co., Assoc.-Mem.Am.Soc.M.E.

Abstract of a paper presented at the Annual Meeting, New York, December 1920, of The American Society of Mechanical Engineers. All papers are subject to revision.

that its value, ignoring for the present the helix of the thread, may be expressed as:

$$\text{Clearance} = y \tan C \qquad [5]$$

The value of x is therefore found by subtracting the amount of interference given by Equation [4] from the amount of clearance given by Equation [5], or

$$x = y \tan C - \frac{B}{360N} \qquad [6]$$

As an example of the use of the above formulæ, we will assume that we wish to hob a thread which has a radius r or 0.5625 in. at the minor diameter with a hob whose radius R is 2.250 in. at its outside diameter with 4 threads per inch. A thread with a relatively large helix angle is taken as the first example in order to show the nature of the resulting side-cutting of a hob. The thread has an included angle of 60 deg., making C = 30 deg., and N = 4. The value of B is taken from 0 deg. to 12 deg., which gives the following values for x and y:

For B = 0°	2°	4°	6°	8°	10°	12°
x = 0	−0.00114	−0.00176	−0.00194	−0.00157	−0.00064	−0.00084
y = 0	0.00043	0.00176	0.00386	0.00691	0.01092	0.01589

The above as well as intermediate values are plotted in Fig. 3-A at the left, and the actual path of the cutting point is shown at the right. These curves show the general form of the side-cutting of any point on the cutting face of a thread hob.

This cutting face of the hob is made up of an infinite number of points. As the positions of these points vary, the ratio between R and r varies, as also does the helix angle of the thread, and therefore each cutting point travels in a different form of path. Thus, in order to determine the resulting form of a thread cut with a hob it will be necessary to plot the paths of a few other points. A point 0.20 in. higher on the flank of the thread will therefore next be taken. This gives R = 2.050, and r = 0.7625, as before, C = 30 deg. and N = 4, and the values for x and y with these factors are as follows:

For B = 0°	1°	3°	5°	7°	9°
x = 0	−0.00061	−0.00126	−0.00117	−0.00032	−0.00136
y = 0	0.00015	0.00143	0.00398	0.00786	0.01318

These values are plotted at the left in Fig. 3-B. The actual path of the cutting point is shown at the right.

A third point 0.40 in. above the bottom of the thread will also be taken. This point is beyond the top of the thread, but it is taken to accentuate the distortion developed by hobbing. In this case R = 1.85, r = 0.9625, C = 30 deg., and N = 4. The values for x and y with these factors are as follows:

For B = 0°	1°	3°	5°	7°
x = 0	−0.00057	−0.00093	−0.00026	−0.00151
y = 0	0.00022	0.00199	0.00566	0.01104

The above values are plotted at the left in Fig. 3-C. The actual path of the cutting point is shown at the right.

In order to show more clearly the nature of the side-cutting of hobs, the curve in Fig. 4 is plotted in an exaggerated form with the intervals along the y-axis equal to 0.001 in., and those along the x-axis equal to 0.0001 in. The curves shown in Figs. 3-A, 3-B and 3-C are plotted to this scale and brought together proportionately; that is, the origins of these curves are spaced equally from the bottom, but these spaces are not to scale. This distorts still further the exact shape of the curve, but its general properties are correct.

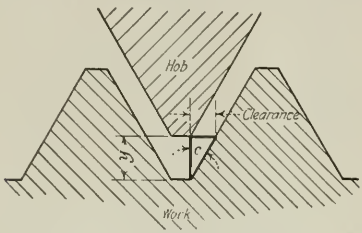

Fig. 2 Diagram Showing Clearance between Hob and Work

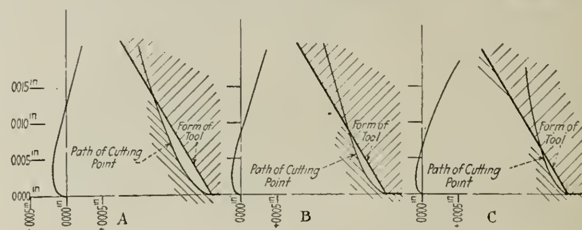

Fig. 3 Curves Showing Paths of Cutting Point

This curve shows the general nature of the distortion in the form of a thread which is caused by the side-cutting of the hob. It will be noted that it is a double curve, the lower part (below the line A–A) being developed by the bottom corner of the hob tooth while the upper part (above the line A–A) is developed by the overlapping paths of successive cutting points on the cutting face of the hob. It is evident that the distortion shown at the bottom of the curve is inevitable and no correction in the form of the hob is possible that will eliminate it. It can be reduced in many cases, however, by making the hob smaller in diameter. On the other hand, the distortion shown in the upper part of the curve can be eliminated by changing the form of the cutting edge on the hob.

The correction of the hob is determined in the following manner: The greatest amount of side-cutting is done by the bottom corner of the hob. In the foregoing example the tabulation shows 0.00194 in. when B = 6 deg. This is not necessarily the exact maximum. If a closer value is required, the tabulations must be made with increments of B of smaller amounts. Tabulations as shown, however, will be correct to the fourth decimal place, which is sufficiently accurate for most purposes.

If the tooth of the hob is narrowed at each point of the cutting edge by the amount which it side-cuts the thread form, the contour of the thread above the line A–A in Fig. 4 will be correct and in most cases it will be found that the correction in a straight line will be sufficiently accurate as the resulting error will be negligible.

Fig. 5-A represents the form of a thread cut with a hob having the form of the cutting edges identical with the true form of the thread. In this figure,

C = half included angle of thread
F = width of flat of thread at the root or minor diam.
r_1 = largest value of r employed (radius of major diam.)
r_2 = smallest value of r employed (radius of minor diam.)
x_1 = maximum minus value of x for r_1
x_2 = maximum minus value of x for r_2
$(r_1 - r_2)$ = depth of thread
$2(r_1 - r_2) \tan C + F$ = width of space at major diameter (outside).

Fig. 5-B illustrates a corrected hob and the form of thread cut with it. In this figure,

$F - 2x_2$ = width of flat at bottom of hob form
$2(r_1 - r_2) \tan C + (F - 2x_1)$ = thickness of hob form at top
C' = half the included angle of corrected hob.

If the cutting edge of the hob is kept as a straight line, the tangent of half the included angle of the hob form will be equal to half the difference between the widths of hob form at the top and bottom divided by the height of the form. Using the values shown in Fig. 5-B, we have the following:

$$\tan C' = \frac{2(r_1 - r_2)\tan C + (F - 2x_1) - (F - 2x_2)}{2(r_1 - r_2)}$$

$$\tan C' = \tan C + \frac{F - 2x_1 - F + 2x_2}{2(r_1 - r_2)}$$

$$\tan C' = \tan C + \frac{x_2 - x_1}{r_1 - r_2} \qquad [7]$$

It will be seen from Equation [7] and also from the figures that a corrected hob will have a greater included angle than the thread

x_3 = maximum minus value of x for r_3

K = difference at r_3 between straight-line correction on hob and true correction

$$\frac{x_2 - x_1}{2} + x_1 = \frac{x_2 - x_1 + 2x_1}{2} = \frac{x_2 + x_1}{2} = \text{correction at } r_3 \text{ when hob form remains a straight line.}$$

$$K = \frac{x_1 + x_2 - x_3}{2} \qquad [8]$$

If the rounding or fillet at the bottom of the thread as shown in Fig. 5-B is objectionable, the point of the hob may be extended by an amount about equal to y_2, provided that such an undercut is permissible. By so

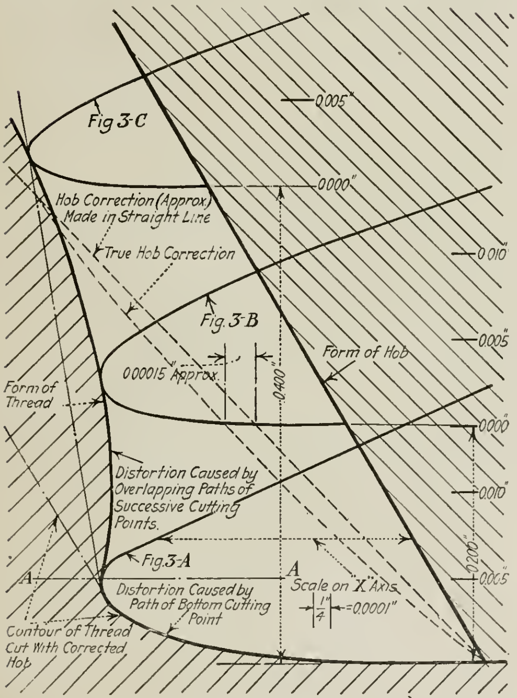

FIG. 4 CURVES SHOWING SHAPE OF CUTTING PATH

doing an almost theoretically perfect thread form will be secured. Theoretically, the point should extend slightly more than y_2, as at this point r becomes smaller and R becomes larger than the values of r_1 and R_1. Referring to Equation [3], this increase in the value of R will increase the value of r'. Referring to Equation [1], this increase in the value of r' and the decrease in the value of r will increase the value of y. But for all practical purposes an extension on the point of the hob of the nearest even dimension to y_2 will usually be sufficiently accurate. On standard threads cut with hobs the resulting error will be in fifth or sixth decimal place.

For the purpose of simplifying calculations tables have been

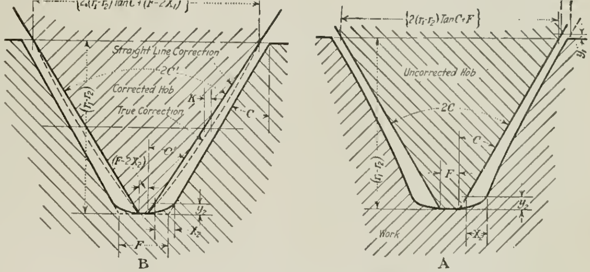

FIG. 5 FORM OF EXTERNAL THREAD CUT WITH UNCORRECTED AND CORRECTED HOB

by the radius of the work to obtain the value of y. The values of y/r may be obtained by interpolation when the value of r/R does not agree with any of those given. The values given under $B/360$ are divided by N and substituted in the equation $x = y \times \tan C - (B/360N)$ to obtain the value of x.

In order to illustrate the use of these tables and to determine the effect of varying the diameter of the hob, values are given in the complete paper for an Acme thread (5 threads per inch, one inch in outside diameter) cut with three hobs, the first one inch in diameter, the second two inches in diameter, and the third four inches in diameter. An Acme thread is selected because the smaller included angle of thread results in more side-cutting, thus making more pronounced the effect of varying the diameter of the hob. The depth of an Acme thread of this pitch is 0.110 in. The included angle is 29 deg. The width of the flat at the root of the thread is 0.0689 in.

The final value of the included angle, $2C''$, as given by Equation [7] is found to be 29° 59′ 26,″ and in the particular case chosen the difference between the angle of the hob and angle of the work is 59 min. 26 sec. The correction is therefore made in a straight line. By means of Equation [8] the difference K between this correction and the true correction at the middle of the flank is also determined as 0.000064 in. This is negligible and can safely be ignored. In fact, it is much less than the probable error in the hob.

From the values derived in the complete paper the following tabulation is also made to show the various effects of varying the diameter of the hob. (See Fig. 5-B.):

Hob. diam. =	1.000 in.	2.0000 in.	4.000 in.
x_2 =	0.002695	0.003475	0.004048
y_2 =	0.008912	0.012344	0.014422
$2C'$ =	29° 59′ 26″	30° 0′ 16″	30° 0′ 54″
$F - 2x_2$ =	0.0635	0.0619	0.0608
K =	0.000064	0.000054	0.000026

From this tabulation it will be seen that the amount of side-cutting at the bottom of the thread (x_2) increases as the diameter of the hob is increased. The height of the fillet at the bottom of the thread (y_2) also increases as the diameter of the hob increases, in fact, it increases about three times as much in this case as x_2. The included angle of the corrected hob ($2C''$) increases very slightly as the diameter of the hob increases. The width of the point of the corrected hob ($F - 2x_2$) varies less than 0.003 in. as the diameter of the hob is increases from 1 in. to 4 in. The dimension K in Fig. 5-B is reduced as the diameter of the hob increases.

The correction for angle used in these solutions is a chordal correction. This shows a slight change in angle as the diameter of the hob varies. A geometrical solution of this side-cutting will show that, except for the fillet at the root of the thread, the profile is unchanged regardless of the diameter of the hob. There-

Increasing the Capacity of Old Locomotives

By C. B. Smith,[1] Boston, Mass.

The usual policy of the railroads with reference to the purchase of new locomotives and the conversion of old ones is not, in the opinion of the writer, as well provided for as the demands of the service require. The difficulty lies in the fact that shop facilities are inadequate, a large amount of both time and money being unnecessarily consumed in order to keep locomotives in service. The problems of adapting the old-type locomotives to suburban and local service are discussed and the items which are to be considered in any program for increasing locomotive capacity are listed. The author also cites examples of satisfactory reconstruction which justify the improvement program he advocates, and states that the application of all the desirable auxiliaries to old engines is prohibitive without a radical provision for carrying out such a program.

In these days of the high cost of railroading, responsible officers of the mechanical departments realize that the necessity for reducing the cost of all locomotive operation and maintenance is more urgent than ever. Such saving can be accomplished in two ways, one by using new and modern locomotives, the other by rebuilding old types. The purchase of new locomotives, however, is usually confined to the largest units permissible for each type required, and they are equipped with superheaters and other modern devices as selected by the purchaser. Older engines of modern type, but not originally supplied with superheaters, are also being so equipped at general shoppings of these engines on the greater number of the roads of the country, and as rapidly as local conditions will permit.

On the majority of our roads there are still locomotives of the earlier modern types whose general features of construction are satisfactory, and which only require modernizing to make them economical transportation units. Improvements for such classes of locomotives may include, in addition to superheaters, piston valves in place of slide valves, outside valve gears in place of Stephenson motion, and such other improvements as are usually made upon engines at general shoppings.

The replacement or betterment of the older locomotives "in kind" is becoming more of a problem where suburban and local passenger service and branch-line traffic still require the maintenance of the lighter types of locomotives that can handle such traffic. Such engines are periodically returned to the shops for repairs, and the frequency of these shoppings could be reduced and mileage between them increased if the time were taken at one shopping to modernize them. Extensive reconstruction, however, requires a longer shopping period and reduces the number of engines available for road service.

The items which are to be considered in any program for increasing locomotive capacity are:

1 Superheater
2 Pyrometers
3 Brick arch
4 Valve motion
5 Mechanical stoker
6 Power reverse gear
7 Automatic fire door
8 Feedwater heater
9 Improvements in boiler design when new boilers are required
10 Improved boiler circulation
11 Increasing firebox heating surface
12 Flexible staybolts—breakage zones
13 Covering steam pipes
14 Flange oilers
15 Automatic driving-box wedges on heavy locomotives
16 Steam-pipe joints at smokebox
17 Pneumatic bellringer
18 Chime whistle on freight—more audible to train crew.

These items are numbered for convenient reference and do not necessarily indicate the order of importance.

The aggregate of such improvements results in a locomotive which in proportion to its capacity will produce service results comparable with those of entirely modern construction, and at a cost approximately one-half that for a new locomotive of similar capacity. The difficulty in carrying forward an extensive reconstruction program, however, is in finding the shop facilities either on the railroad or among the locomotive builders in order to advance the work at a satisfactory rate of progress. Nevertheless, despite this difficulty the results which could be obtained from the operation of reconstructed locomotives, if they could all be rebuilt within the next few years, would justify a special effort on the part of railroad managements to bring it about.

On roads where the number of old locomotives which warrant rebuilding are sufficient to require a period of more than three years to complete the work, it would seem necessary to arrange for enlargement of shop facilities in order to hasten the reconstruction. If, however, adequate shopping facilities are not forthcoming, the improvement program for locomotives must be confined chiefly to the application of superheaters and the substitution of piston for slide valves; together with the minor but relatively important betterments that may usually be applied at the shopping period.

Some of the engines built within the past ten years have developed weaknesses in frames and in parts of running gear. It has proved justifiable to reconstruct them by substituting new parts of stronger design and thus avoid recurring breakages which interrupt both the road service of these engines and the repairs to others. On roads whose traffic and service conditions now demand and will continue to demand the use of light locomotives for passenger trains and freight trains on branch lines, the better classes of the light locomotives should also receive their share of improvements along with the heavier power.

Old locomotives requiring new boilers have very generally been scrapped, but where light train service demands no heavier engines than formerly, the writer believes it advisable to rebuild such engines with radial-stay boilers, superheaters, new piston-valve cylinders, main frames when necessary, and outside valve gears. If there is to be no increase in the boiler pressure over that formerly carried by the locomotive and the valve motion has given little trouble by breakages, the Stephenson motion may be connected to the piston valves through the usual rocker-shaft connections.

Old locomotives that are unsatisfactory as to wheel arrangement may be rebuilt and changed to another type and service. One road has converted 2–8–0 type or Consolidation locomotives to 0–8–0 switching service by removing the leading truck, applying a new boiler, new cylinders, outside valve gear, power reverse gear, and modifying the frames as required. The boiler was located to properly balance the engine.

The old eight-wheeled, American-type locomotives having crown-bar boilers with deep fireboxes between frames have become obsolete on many large roads, but on the small roads and on branch-line and local train service in much of the New England territory these engines, modernized as far as consistent, should be carefully considered where the traffic conditions warrant.

Because of limiting weight conditions, Mogul or 2–6–0 type locomotives have been assigned to passenger-train service on some outlying divisions. The application of superheater and piston-valve steam chests with outside steam-pipe connections as the principal features of improvement, has increased the economy of these engines, added one passenger car to their tonnage capacity, and reduced train delays. Outside valve gears were not applied, shop limitations preventing, but their addition is desirable.

Atlantic-type locomotives having outside valve gears have had their capacity and economy increased by the application of the superheater. This work permitted the use of the engine in long-distance through service which was not previously successful.

Consolidation locomotives reconstructed with superheaters, new piston-valve cylinders, outside valve gears, new front-frame sections, and frame cross-ties have also had their capacity increased,

[1] Mechanical Engineer, Boston and Maine Railroad.

Abstract of a paper presented at the Annual Meeting, New York, December 7 to 10, 1920, of The American Society of Mechanical Engineers. All papers are subject to revision.

The following paper is a discussion of the problem of providing adequate facilities for the proper maintenance of locomotives at engine terminals. The location, size, and general layout of the terminal are dependent on various elements, the two principal factors being character of work to be performed and location of the general locomotive repair shop. The necessity for providing modern facilities is discussed with a view of awakening an interest in this subject, which has an important bearing on the ability of the railroads to handle the increased traffic demands of the country. The various structures which comprise the terminal are treated separately with more or less detail, having in mind that the entire problem must be handled in such a way that it will be of service in modernizing existing locomotive terminals, as well as to provide information of value in designing new terminals. The author has purposely omitted reference to detail construction of buildings as these features generally conform to the railroad's standard practice.

ENGINE terminals play an important part in the operation of the railroad, as the transportation department is at all times entirely dependent upon them for its supply of serviceable power for the movement of both passenger and freight trains. Should the capacity of the terminal or the facilities for making repairs be inadequate, the result will soon reflect itself in more time being required to prepare engines for service and more frequent detention on the road due to failures.

The general layout of the terminals, also the extent of repair facilities to be provided, depend entirely on their location with reference to the general locomotive repair shop. When located in close proximity it is necessary to provide only such facilities as may be necessary to make the general run of roundhouse repairs, depending upon the main shop for the manufacture and supply of a large percentage of materials required for use at the terminal. But when engine terminals are located some distance from the general locomotive repair shops, they should be provided with enlarged facilities so as to perform all the necessary machine, blacksmith, and boiler-shop operations required when making more extensive repairs, and be entirely independent of the main shop. It is important, however, to eliminate at such terminals the manufacture of such standard parts as may be produced elsewhere at less cost when made in quantities. At outlying points where only light repairs are made to maintain locomotives in serviceable condition, such repair facilities as described above are not necessary. In this connection Figs. 1 and 2 are of interest as they illustrate typical layouts of modern locomotive terminals.

The location of the engine terminal with reference to the general locomotive repair shop will have some bearing on the necessity of performing relatively heavy repairs at the terminal. Where they are within reasonable distance of each other, it may be desirable to have a considerable part of the heavy repair work transferred to the main shop, where the repairs can be performed more expeditiously. On the other hand, this class of work has a tendency to interfere with the output of the locomotive repair shop, and especially so if it is found difficult to maintain the necessary quota of class repairs, considering the equipment as a whole. In such cases it would appear more desirable to increase the engine-terminal forces and provide sufficient facilities to at least make Class 5 repairs and the general run of heavy running repairs, including the removal and reapplication of a part or complete set of flues.

Where it is found desirable to perform such heavy repair work, it should preferably be done in a small building located adjacent to the machine shop, and provided with several tracks for holding engines and an overhead crane or power-driven locomotive screw hoist to facilitate the removal of all wheels. This feature is very

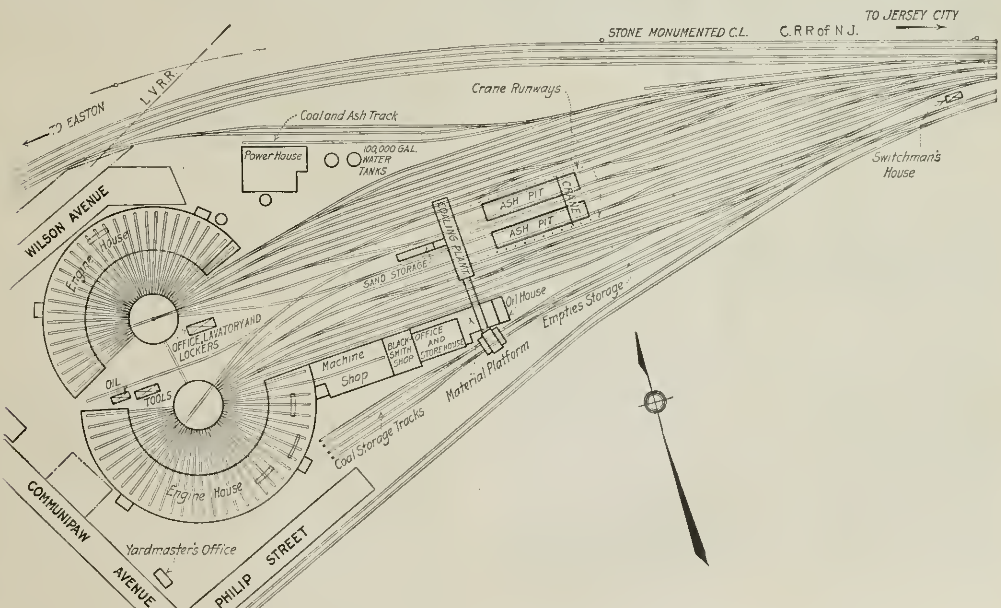

Fig. 1 Engine Terminal, C. R. R. of N. J., Communipaw, N. J.

This terminal handles daily an average of 200 locomotives. It is located 8 miles from the general locomotive repair shop and present facilities only provide for making ordinary repairs

[1] Asst. Supt. Motive Power, C. R. R. of N. J., Mem.Am.Soc.M.E.

Abstract of a paper presented at the Annual Meeting, New York, December 7 to 10, 1920, of The American Society of Mechanical Engineers. All papers are subject to revision.

desirable, especially if heavy locomotives are to be handled. It also increases the track capacity within the roundhouse to that extent and repairs can be made more promptly and economically.

The arrangement of tracks at the engine terminal, including inbound and outbound tracks, will depend entirely on the location and available space assigned. The successful operation of the terminal requires a complete analytical study of the entire project from an operating standpoint, taking into consideration the number and type of locomotives to be handled and the possible future increase in requirements. The number of locomotives to be handled will determine the size and arrangement of facilities to be provided.

The introduction of numerous specialties on modern locomotives together with the necessity for complying with Interstate Commerce Regulations covering the inspection and testing of locomotives and their appurtenances require a more extensive inspection and maintenance force.

Coaling Stations and Sand Storage

The type of coaling station selected must depend on the number of engines handled, the number of tracks which may be available for coaling engines and the kinds of coal to be handled. Some roads in the East use bituminous, broken anthracite, and buckwheat. Where the quantity of coal handled is small, the locomotives can be coaled from an elevated platform using one-ton buckets or by means of a locomotive crane direct from car. When it is necessary to deliver coal to two or more tracks, a mechanical type of coal-handling apparatus is generally installed. (See Fig. 3). Marked improvements have been made in receiving, hoisting, and distributing equipment, which has resulted in a smaller operating force being required. Measuring devices are also installed for recording the amount of coal delivered to tenders. An electric winch should be provided at large terminals at the loaded-coal-car track so that cars can be hauled to position over the track hopper.

The sandhouse should be located at the coaling station. Sufficient wet-sand storage space should be provided as well as means for drying the sand by coal stove or steam. Compressed air should also be available so that the sand can be delivered to overhead storage bins, having suitable outlets to deliver the sand direct to engine by gravity. All important engine terminals should have a complete installation of this character.

Ash Handling

At small engine terminals provisions are made to handle cinders in various ways, one method is to provide a pit located between rails. Cinders are shoveled to track level and loaded into cars by hand or locomotive crane. This system is satisfactory where but few engines per day are handled. At larger terminals a depressed track is installed adjacent to the pit or ash track and the cinders are shoveled by hand into cars.

Limitations of space at some terminals may not permit the use of longitudinal cinder pits. In such cases, transverse pits have been introduced whereby cinders are dropped directly from ashpan into closed hoppers, located between rails, and then deposited into buckets mounted on trucks, which operate on narrow-gage tracks beneath the hoppers. After filling, the cinder bucket is pushed clear of the cinder track and handled by suitable hoisting mechanism, the cinders being deposited directly into cars. Several running tracks can be equipped as stated, requiring but one long transverse pit beneath and using one or two buckets, depending upon the width of the pit.

A number of recent installations provide for the dumping of the cinders directly into large metal buckets beneath the track. Mechanical means are provided to withdraw the buckets laterally and upward, dumping the contents into the cars.

During recent years the tendency when constructing large terminals has been to install pits filled with water. (See Fig. 4). The cinders drop into the water and move toward the center of the pit, due to the inward slope of the outer wall, and are removed either by a locomotive crane or by an overhead crane traversing the entire length of the pit, the cinders being deposited by means of grab buckets directly into cars located on the loading track.

Steam-jet ash conveyors can be installed to advantage where ample supply of steam is available. This system consists of an 8-in. cast-iron pipe made exceedingly hard to withstand wear, with intakes provided at suitable intervals. The cinders are drawn by suction through the main pipe line and then propelled by means of the steam jet direct to car or storage bin, suitably located. Cinders handled in this manner are not wetted down until they enter storage bin, where a water spray is provided. This type of cinder conveyor has proved very satisfactory for handling cinders in power houses and should give good service when installed in connection with small engine terminals.

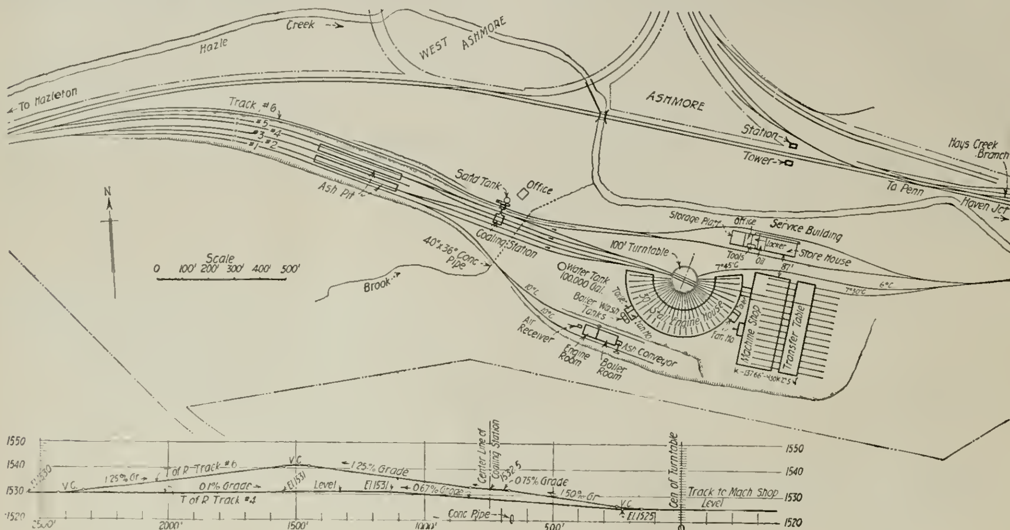

Fig. 2 Engine Terminal, Lehigh Valley R. R., Ashmore, Pa.

This terminal handles daily an average of 70 engines. It is located off the main line and adequate facilities are provided to take care of general repair work in addition to running repairs.

stall 110-ft. tables to insure greater leeway for balancing the locomotive under all conditions.

Through-girder and top-deck types are used according to circumstances. For propelling the table electric tractors are generally used, with current supplied either through conduits brought through the center of the table or from overhead collectors mounted on steel frame. Where electric current is not used extensively, pneumatic turntable tractors can be installed, using air taken from trainline of locomotive or from shop line. In the latter case the air supply is usually brought through the center of the table, using a swivel connection.

Inspection Pits

Inspection pits are now being installed at a number of large engine terminals. These are located on the inbound tracks with the view of making inspection of locomotives before they are placed over the cinder pit. Fires can then be withdrawn when the engines pass over the cinder pit, if inspection develops defects which warrant this procedure, thus saving time and expense involved if engine was inspected within the roundhouse after passing over cinder pit. There are many advantages in having inspection made at this time as the foreman by means of pneumatic tubes can be furnished with both the engineer's and inspector's reports showing work to be done before engines are placed within the shop.

These inspection pits are generally made about 100 ft. long, two in number, and protected with a shed. Special arrangements are provided to permit inspectors to enter the pits. Proper drainage and lighting facilities are also required. In lieu of reporting on inspectors' reports such work as loose nuts, missing cotters, etc., it would be desirable to station at these inspection sheds mechanics who can perform this work at once, thus saving time in locating these defects in the shop after being reported.

Heating and Ventilation—Lighting

Heatinga nd ventilation are of first importance in a modern and efficient roundhouse. A combined heating and ventilating system should supply sufficient air for the quick removal of smoke, gas, and vapors. Ventilating sash, louvers and other openings should be provided at the high points of the room to supplement the forced system by directing the flow of air currents and facilitating the removal of hot gases. This feature should be carefully considered, for in roundhouse ventilation it is not so much a question of diluting the air as it is of establishing a positive flow of air which will carry the gases along with it.

It is sometimes necessary, due to the requirements of local ordinances or because the type of house prevents the use of smoke jacks above the locomotive stacks, to install an exhaust system so as to remove gases directly from the locomotive smokestacks. In the latter case connections are made to the smokestacks by means of swinging hoods. This system is not necessary from a ventilating standpoint, and should only be installed where conditions compel its use.

With the usual type of indirect system the fan rooms, one or two in number depending on the size of the house, should be located midway of the length of the house to be served, thereby reducing the temperature drop of the air in the duct as well as the friction head against which the fan must work. The quantity of air supplied together with the number, size, and location of air outlets depends largely on the type, size, and location of the roundhouse. The amount of heat to be supplied with the air is also a variable factor and should have careful study so as to provide a comfortable working temperature under the conditions obtaining in roundhouse operation.

In roundhouse heating it is too often considered sufficient to supply a certain temperature and change of air without consideration of the variable factors governing a proper design. When given the same study and attention as other heating problems it is quite possible to produce a system uniformly satisfactory and economical in operation and first cost.

of the day when it would naturally be considered necessary. Good natural and artificial light will reduce accidents, provide greater accuracy in workmanship and simplify the supervision of the men. Fig. 5 is an example of a well-lit roundhouse.

Much needed improvement is desired in connection with artificial lighting of engine terminals. In the roundhouse proper, lights mounted on the outer wall and reflected between engine pits have given satisfactory results when augmented by sufficient lights

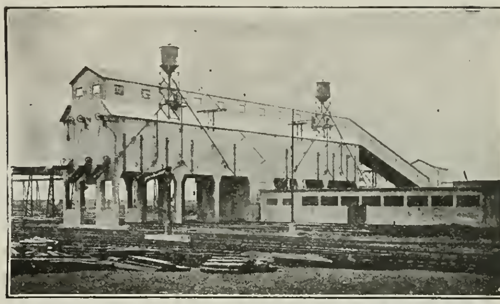

Fig. 3 Coaling Station, C. R. R. of N. J., Communipaw, N. J.

This reinforced-concrete coaling station has a storage capacity of 1600 tons It serves 10 tracks with 3 kinds of coal.

suspended from the ceiling to afford general illumination. Machine-shops, etc., should be provided with a general or overhead lighting and also supplemented by individual lamps conveniently placed, preferably on brackets so that they may be adjusted.

For lighting the roundhouse circle, flood lights should be used

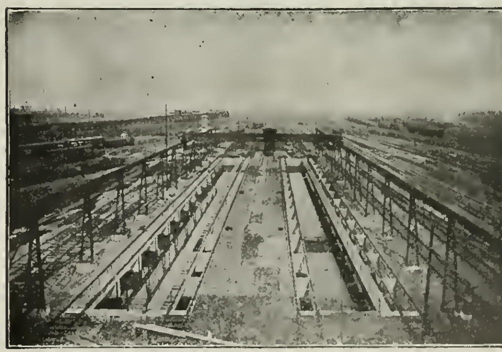

Fig. 4 Ashpits, C. R. R. of N. J., Communipaw, N. J.

This type has been adopted as standard by many roads.

whenever possible as general illumination will add considerably to the safe movement of locomotives to and from turntable and engine house. Ashpits can be illuminated by rows of reflector lights placed on poles, and similar provisions can be made at other points beyond turntable or by the use of flood lights on the top of coaling stations.

Hot-Water Washout and Refilling System

Facilities should be provided for washing out boilers using hot water under pressure and refilling with hot water after washing. Actual time savings can be made compared with the old system of washing out and refilling with cold water: boilers are washed out more thoroughly and strains within, due to expansion and contraction, are considerably reduced, resulting in decreased cost of boiler maintenance. There are two types of installations for this

purpose in general use, one of which utilizes the blow-off water for washout purposes only, while the other utilizes as much of the blow-off water as necessary for this purpose and the remainder, after being clarified, for refilling purposes. As blow-off water is always soft and becomes clarified soon after storage, it is of course the best water for the generation of steam and its reuse in this manner is responsible for the greater efficiency of the latter type of installations.

Hot-water washout and refilling systems can be economically installed in any size to meet the requirements of any engine terminal. Where such systems have been introduced, there is a material reduction in time required to do this work. Boilers have been blown off, refilled, fired, and steam pressure brought up to 100 lb. within from two to three hours. This does not include such time as may be required to make necessary repairs to boilers.

Wheel-Dropping Facilities

The usual wheel-dropping facilities consist of a drop-pit system

Fig. 5 Interior of Roundhouse, C. R.R. of N. J., Communipaw, N. J.

which provides for depressed pits at right angles to shop track, using telescoping pneumatic or hydraulic jacks for lowering and raising wheels, separate pits and jacks being installed for handling driver and engine-truck wheels. Generally but one pair of wheels can be handled at one operation, and if necessary to drop all drivers in order to take up lateral or change tires, considerable time is lost in moving the engine over the drop pit.

Screw-jack locomotive hoists especially designed for unwheeling locomotives are being more extensively used at engine terminals, and their use has made possible a large saving in both time and labor. These hoists operate with a high degree of safety as compared with the drop-pit system; furthermore they can be located within the roundhouse or installed in a separate building, in which case it would be desirable to also install the wheel lathe and other tools and appliances for taking care of heavy running repairs.

Machine, Boiler and Smith Shops

Old and obsolete tools should be replaced by modern machine tools, which insure increased production at lower costs and the work being done more accurately and promptly and power maintained in better condition. Individual motor drive for the larger machines and group drive for the smaller machines is preferable. Ample space should be provided for this department, and the class of work to be performed will determine the number and type of machines required.

Space for the boiler and smith departments is generally provided adjacent to the machine shop. Facilities should include steam hammer, forges with down-draft hoods (number and size to suit work to be performed), punch and shear, plate-bending rolls, straightening plate, flange, fire, etc. Stock flues, sheet iron and bar iron and steel should be kept outdoors in covered racks.

Autogenous cutting and welding outfits are also considered indispensable and are used principally in making repairs to locomotive fireboxes, engine frames, and in reclaiming miscellaneous parts which can readily be repaired by this process. Provision is also made for the pipefitting, tinsmith and air-brake departments in the machine-shop building. Locker rooms and toilet facilities for both shop men and engine crews are essential. Considerable time in making repairs can be saved by providing jib or overhead cranes in the roundhouse and machine shop, to enable heavy parts of engines to be handled with the least amount of labor.

Oil House and Store House

Oil houses should be separated from other buildings, should be of fireproof construction, and of a size to suit the requirements. The storage tanks are generally in the basement and filled from the floor level above from barrels through pipe line and delivered from storage tanks to the faucets by special hand pumps equipped with measuring devices. When large quantities of oil are used, provisions are made to fill storage tanks in the house direct from tank cars.

This should comprise a structure of ample size, conveniently located to machine shop, with platform and track facilities for handling material to and from cars, building provided with sufficient natural and artificial light, steel shelving, bins, etc., separate alcove for electrical repair shop and provision for office staff on second floor.

Power House

Important engine terminals should be provided with a power plant of sufficient size to take care of the future as well as immediate needs of the terminal. In a number of cases this plant is required to provide steam for thawing snow at switches on main-line track leading to the terminal passenger station and supply heat and light to station buildings, and function in general as a service station. Labor-saving devices should be installed in the way of coal- and ash-handling machinery, automatic stokers and large-capacity overhead coal-storage bunkers. Consideration should also be given to operating with condensers, requiring cooling tower if fresh water is used, the surplus water being delivered to flood ashpit for locomotive cinders if this type is used. Tanks of ample capacity should be located at power house with water mains of proper size supplying water for shop use and filling of tenders at terminal tracks, locating water columns away from switches in cold climates to prevent freezing. At smaller terminals, discarded locomotive boilers are used to furnish steam for power and heat. A close study made of these installations will often reveal the fact that in many cases savings can be effected by the use of modern water-tube boilers.

INCREASING THE CAPACITY OF OLD LOCOMOTIVES

(Continued from page 12)

and have been successfully used in regular freight service on a mountain division greatly needing such power.

When rebuilding locomotives there is a favorable opportunity for replacing old tenders as well, transferring the latter to older locomotives for spare use or as substitutes for damaged equipment. When the condition of old steel tender frames requires that they be replaced, the one-piece steel casting and a larger-capacity tank should be used as both will reduce future expense in repairs. The success of autogenous welding eliminates any objections to the use of large steel castings for fear of breakages.

Tanks should be reconstructed in coal space to permit gravity delivery of the greatest amount of fuel that is possible at the coal gates within reach of the fireman's shovel. Application of power-operated coal pushers should be made to tanks where alterations for the gravity delivery of coal cannot be satisfactorily made and where the service conditions will show a saving in expense by its use over hand methods of shoveling forward coal while on the road or at short lay-over stations. Moving forward the rear coal board or plate on tanks and building higher side plates or "dickies" is one method which has been successful in making the maximum amount of coal accessible at the gates.

that it is your desire that I should discuss the subject with particular reference to the steam railroad. For the purpose of outlining briefly my own views concerning the larger problem, I would like your permission to read from a report which I submitted to the Council of National Defense in November 1917:

A nation should have a national transportation system and such a system should embrace and make proper use of all available and suitable agencies. The fullest possible economic coöperation should be encouraged and required between all such agencies. Inasmuch as the business of transportation for hire partakes of a monopolistic character, all agencies so used should be subject to governmental regulation in the public interest.

Among the many agencies of transportation, the following are in most common use: the natural and artificial waterways with the various craft designed to operate thereon; the highways with the different vehicles and contrivances designed to operate thereon; and the specialized roads, such as electric and steam railways with the special equipment designed for each. Other agencies may be developed.

The coördinated transportation system of a nation should be so adjusted that each agency will perform the particular function for which it is best adapted, and, speaking broadly, that country which is provided with the most efficient transportation system—other things being equal—ought to be the most prosperous.

Mr. Theodore N. Vail once told me that for many years it had been his ambition to so develop the telephone system that a man in his own home in any part of the United States could talk with a man in his own home in any other part of the United States, and he very nearly, if not quite, lived to see the realization of his ideal. To my mind the means of transportation should, in effect, be just as universal and all-embracing as the means of communication, and the ideal which Mr. Vail sought to achieve as regards the telephone should be an inspiration to accomplish also the highest development in transportation. Unfortunately, however, we have not yet developed a single agency of transportation of such universal adaptability as the telephone. If we are to have a complete and well-articulated national transportation system, it can only be had, as things are now, by the coördination of a number of different transportation agencies, including the steam and electric railways, the utilization of coastwise and inland waterways, the full economic use of the highways, improved and unimproved, the use of the motor truck, and such other transportation agencies as may be best suited to the particular requirement. Of all the transportation agencies at this time available, particularly for interior service, the steam railroad is undoubtedly the most important.

At the termination of Federal control the steam railroads in the United States had an aggregate length of about 260,000 miles. They also owned in addition thereto approximately 145,000 miles of second, third and other tracks. Further, they owned approximately 2,350,000 freight cars, some 65,000 locomotives and about 55,000 cars designed for passenger-train service—the entire property representing a combined investment of approximately \$20,000,000,000. I am now speaking of those roads subject to the jurisdiction of the Interstate Commerce Commission and which are dealt with in the official reports of that body. More than eight hundred separate and independent companies own and operate the mileage which constitutes the Railroad System, so-called, of the United States.

The new Transportation Act provides among other things that in times of emergency the Interstate Commerce Commission shall have authority to treat all of the cars, engines and facilities of all the railroads, regardless of ownership, in such way as to best serve the interests of the public and the commerce of the country.

The law also lays down a definite rule for the guidance of the Interstate Commerce Commission in the matter of fixing rates and in that connection says that rates shall be fixed so as to yield March 1, 1920, rates *shall* be fixed so as to yield $5^1/_2$ per cent, and *may* be fixed to yield 6 per cent upon the value of the property used for transportation purposes; and the Commission in harmony with the law has fixed rates designed to yield an annual return of 6 per cent upon an aggregate valuation which the Commission tentatively fixed for rate-making purposes in this particular case of about \$19,000,000,000.

If this country were fully developed and if we had already reached the peak load which the railroads will be expected to carry, the railroad problem would be a much simpler one than it is under conditions as they actually do exist. Our country has not stopped growing. It is far from being fully developed. Experience of the past demonstrates clearly that at least \$1,000,000,000 per annum must be provided as a minimum for capital expenditures for new equipment and facilities necessary to keep the railroads abreast of the transportation requirements of the country. If the Government owned the railroads, it could, of course, if the people so desired and Congress so determined, raise, by general taxation, the funds necessary to provide in whole or in part the additional transportation facilities required, or it could fix rates sufficient to provide either in whole or in part the large sums of new capital needed on that account each year. However, Congress by virtue of the Transportation Act of 1920 has decided that the policy of private ownership and operation of the railroads shall be continued and has undertaken to provide a plan of regulation to make that policy possible and successful. The owners of the properties, that is, the railroad companies, can only obtain new capital provided that they can satisfy investors of their ability not only to pay the agreed rate of interest, but can also give satisfactory assurances of their ability to repay the principal sum itself when due.

Congress undoubtedly believed when it fixed the rule for rate-making in the Transportation Act that it had provided a plan that would enable the railroads to establish and maintain a firm basis of credit, sufficient in fact to enable them to raise in the aggregate at least \$1,000,000,000 of new capital each year. It was clearly developed during the hearings preliminary to the passing of the Act that unless the railroads were able to raise that amount of new capital each year, they would not be able to provide adequate facilities to take care of the business of the country and in consequence private ownership as an economic policy would fail. The people in this country cannot afford to experiment with or to have any system of ownership or control of the railroads unless such system is able by and of itself to provide, as needed, the additional facilities necessary to move the growing traffic of the country. Personally, I believe the new Act will enable the railroads to do this. But if it should develop that the rate of return permitted under the law is insufficient to accomplish the end desired, it will then be necessary either to amend the law so as to provide a more liberal return or adopt some other method. The only alternative would seem to be ownership and operation by the Government.

The Transportation Act contains one other far-reaching provision, and in my opinion a wise one. It authorizes, as I have already said, the Interstate Commerce Commission in times of emergency to issue such orders concerning the use of the equipment and facilities of all the railroads as may best serve the requirements of the public for transportation. The law also states that the Commission may in the exercise of this power use such agencies as it may select.

The railway managers shortly after the termination of Federal control, and actuated by a desire to coöperate with the Interstate Commerce Commission in an effort to comply with the real spirit of the new Act, formed an Advisory Committee of eleven railway presidents geographically selected. A Car Service Division has also been established in Washington under the direction of an Executive Manager, who reports to the Advisory Committee.

[1] President, Baltimore and Ohio Railroad.

Presented at the Annual Meeting, New York, December 7 to 10, 1920, of The American Society of Mechanical Engineers. All papers are subject to revision.

This Car Service Division has a staff of about 150 persons, and it receives daily reports from all the railroads in the United States concerning transportation conditions, particularly as affected by car supply. This Car Service Division works in close harmony with the Bureau of Service of the Interstate Commerce Commission, and its purpose is to carry out the intent of the law so far as possible by the voluntary coöperation of the separate railroads.

Since the termination of Federal control more than 170,000 empty box cars have been moved on special orders by the Car Service Division from the south and east to the territory west of the Mississippi River, where they were urgently needed. An equal number of open cars have been moved from the western lines into the eastern territory, where they were needed for coal and other shipments requiring equipment of that character. Many other important transportation matters have been handled by the Car Service Division. At all times there has been a full understanding with the Interstate Commerce Commission. In some instances the Commission's support and interest have been supplemented by special service orders which they have issued.

The condition of the carriers' equipment at the termination of Federal control was much below the standard formerly maintained by the railroads under private control. Furthermore, the Government had not been able to, or in any event did not, provide as much new equipment during the twenty-six months of Government control as the railroads had been in the habit of providing during similar periods. The result was that when the railroads were returned to their owners they were inadequately supplied with equipment, and such equipment as they had was in an impaired condition, while there was a larger volume of business offering for movement than at any time before. The situation was further complicated by the switchmen's strike, which began in Chicago early in April and spread to a greater or less extent over the entire eastern region.

The carriers realizing that they were inadequately equipped to handle the unusual volume of business offering, and appreciating that even if the large amount of new capital necessary to purchase new equipment were available, time also was an element to be reckoned with and some months must necessarily elapse before new facilities could be provided, decided that the important thing to do was to make the best use possible of the facilities already available. With that thought in mind they unanimously pledged their best efforts to increase the daily movement of all freight cars to an average minimum of 30 miles per car per day; to increase the average car loading to a minimum of 30 tons per car, and to reduce the number of cars held out of service awaiting repairs to not more than 4 per cent of the total number of cars owned. If these three standards so set up could all be accomplished concurrently, it would in effect be equivalent to adding over 500,000 cars to those available for service. A number of railroads in the United States are already making more than an average of 30 miles per car per day, and on a number of lines the average car load is much in excess of 30 tons per car, and on some lines the number of cars awaiting repairs is not in excess of 4 per cent. But the railroads have not yet been able as a whole to accomplish the standards which they have set up for themselves and it was not expected that the standards would be immediately reached. I am confident, however, that they will ultimately be reached and exceeded. A very marked improvement has already been made. During the month of August the net ton-mileage movement on Class I railroads was in excess of 42,000,000,000 ton-miles, which was a considerably larger performance than ever accomplished before by the railroads in a similar period of time.

In spite, however, of all that the carriers may be able to do with the existing plant, they will not be able to handle all of the business that this country is even now capable of producing. It should be kept in mind that during the war unusual efforts were made to increase productive capacity in all directions. More ground was cultivated than ever before, and larger crops were raised, existing factories were greatly enlarged and new factories of unprecedented size were built. The productive capacity of the country was thereby greatly increased, for war purposes, it is true, but the development is there and can and will be used largely for peace purposes. During the same period the railroad facilities were not increased at all. In fact, it may almost be said that the capacity of the railroads, that is, the carrying capacity, was less at the termination of Federal control than it was at the beginning, for the reason that during the entire twenty-six months of Federal control the Government bought only about 100,000 freight cars, which was approximately the amount that the railroads had been in the habit of buying during each twelve months' period in the past. The number of locomotives bought during the period of Federal control was also considerably less than ordinarily would be purchased during a similar period. No passenger equipment at all was purchased during the period of Government control. It was found that the railroads with their existing plant could take care of the war situation, and properly all men and material available were used in other directions, but in times of peace the people are not willing to accept the character of service which the railroads gave during the war, not is it in the interests of the people as a whole that they should be required to accept such service. In order that the carriers may be able to properly handle the business offered in the future, they must make very large expenditures not only for additional cars and engines, but for additional running tracks and particularly for additional terminals.

So far I have assumed that the commerce of the country would depend largely, if not wholly, upon the railroads for transportation. It seems clear to me, however, that it is in the larger public interest that in developing a transportation system which will be adequate to meet the transportation requirements of our growing commerce, each suitable agency of transportation should be used to the extent that it is economically desirable.

Personally, I believe that the situation should be studied as a whole and along the lines indicated in the recommendation which I submitted to the Council of National Defense in 1917. Each transportation agency should be used to the extent that such use is economically desirable. To make less use than that of each available agency would be wasteful and uneconomic, and if a more expensive agency were used when a less expensive one might be equally available, that practice would also be wasteful and uneconomic. I think in the past there has been a tendency on the part of those who happened to be interested in some particular agency, to try to extend its use in many instances beyond the proper economic limits, and this has resulted in unwise expenditures which in the end proved to be uneconomic and consequently unprofitable. Such mistakes ought to be avoided in the future.

Again, to be specific, I do not believe that the motor truck as now developed and operating on any form of highway can compete in the carriage of long-distance traffic with the steam locomotive running on a steel girder properly supported. I do believe, however, that for short-distance traffic and in sparsely settled communities the motor truck, not only on the improved highway but even on the ordinary dirt highway, may be used in conjunction with the railway and thus afford the cheapest form of transportation. I think the same thing may be said also with reference to some of our inland waterways. I think there should be an intelligent effort to develop all agencies of transportation, each within its own sphere, but all so coördinated with each other as to constitute a nation-wide system which would approximate in its effectiveness the efficiency of the telephone system of which I have already spoken.

Undoubtedly it has happened at different times and places in the past that the railroads have taken business where the out-of-pocket cost, not to mention the cost of capital, has been in excess of the entire revenue. The country as a whole would be better off if such business could be handled in such a way as would give reasonable profits to those engaged in the enterprise. There was a time when railway managers were believed to be opposed to the development of other means of transportation which might become competitors for the business which they were hauling or desired to haul. But whatever may have been the attitude of the railway managers in the past, that is not their attitude at the present time and I am certain that they will be glad collectively or individually to coöperate with all other transportation agencies in such way as will inure to the greatest public good, because in the end all enterprises of an individual character must be tested by that rule. Whatever contributes to the public good is likely to endure, and anything inimical to the public good is certain to fail.

small way. Being private enterprises there was brisk competition and branch lines were constructed to get business which might otherwise go to a competitor. The same thing occurred in the construction of tracks to industries; the railroads assumed all of the expense, but they were able to reimburse themselves by rates charged on the business.

We do not need to follow the history of unrestricted competition on through the period of concessions and rebates as it is past history. Its results were the cause of the beginning of the regulation of railroads and of the gradual evolution of the theory that railroads were not private enterprises but public utilities, and that they should be operated in such a manner as to give everyone the same service.

Early Systems of Regulation

Systems of regulation were inaugurated by the National Government and by the separate states, and like any new power granted it was executed in all manner of ways. Politicians found it a ready excuse to make capital for election to office, and the early practices of railroad managements, while perfectly lawful at the time, were held up as criminal. The result was a wave of popular complaint against the railroads This, as usual, affected the regulatory bodies, and they gave the railroads the worst of every question that came before them.

The ultimate result was that railroads could not raise rates, but on the contrary, rates were continually being lowered, it even going so far that state legislatures undertook to decide what passenger rates should be, with the result that in several states a two-cents-per-mile rate was fixed as the maximum that should be charged on any railroad in these states regardless of whether it was over main lines or branches. The inevitable result was the bankruptcy of many railroads and the cessation of railroad extension and of facilities to take care of the growth of business.

But with the operation of the railroads by the Government it was soon shown that it was lack of facilities and rolling stock rather than private ownership that was handicapping the railroads, and the curtailment of service by the Government, in an effort to operate the railroads and their failure to expend the money necessary to furnish the added facilities, soon brought a demand from the public for a return of the railroads to their owners and an increase in rates that would permit them to furnish the facilities to give the public proper transportation service.

As a result of this the Esch-Cummins Bill was passed, making it incumbent on the Interstate Commerce Commission to permit rates to the railroads that, in addition to paying operating expenses, including a fair amount for depreciation, would yield a return of 6 per cent on a fair value of the property devoted to transportation purposes, either on the railroads as a whole or divided into such groups as the Interstate Commerce Commission might consider advisable.

The Duty of the Interstate Commerce Commission

Now, with a sane and common-sense law by which the railroads are to be permitted to earn a fair return on the money invested in them, and the acknowledgment that the public must pay a rate that will give a fair return on the investment, it becomes the duty of the Interstate Commerce Commission and the railroad managements to make a study of the situation and to see, first, that adequate facilities are provided to give the public the best transportation possible, and, second, to see that this is done at the least cost to the public.

In the past, due to unrestricted competition, many facilities have been duplicated, such as tracks from two or more railroads into the same industry, and branches of two or more railroads tenance and upkeep, the cost of operation and interest on the investment, of duplicate property.

These branch lines were built in the days when there were ordinary dirt wagon roads and all teaming was done with animals. Today, with the advent of the automobile and motor truck have come the so-called "good roads," and where these roads have been built passenger automobiles can travel 25 to 50 miles per hour and motor trucks loaded with produce or goods can travel 15 miles per hour, or, in other words, at practically the same speed as branch-line passenger and freight trains.

It can readily be seen that with the introduction of a class of locomotive that requires no rails and which can be used by the public at large, the use of the railroad, within the limits of the practical use of a single unit of transportation, must become less and less as good roads are constructed. Why, therefore, should the public be obliged to pay in railroad rates the cost of upkeep, operation, and interest on the cost of a branch line of railroad which they do not need, as with a good hard-surfaced road and no branch line of railroad someone would operate a motor bus for passengers and motor express for less-than-truck-load freight? A careful study should be made of branch lines of railroads, and where they are "good roads" of the hard-surfaced class, over which the business now handled by the railroad can be handled by motor trucks and buses, the question of dismantling the branch line of railroad should be given serious consideration.

The Cost of Branch Lines

Branch lines were formerly cheaply built, at from \$12,000 to \$15,000 per mile; they had narrow roadbeds, light rail, light bridges and fewer ties per rail than main lines; and they were equipped with locomotives that had become too light for main-line traffic. With the constant increase in the weight of locomotives on main lines for the past 15 years, there are no light engines to put on branch lines, and the result is that what are now perhaps light main-line engines but are heavy for branch-line service, are sent to the branches. This, and the rapid increase in the size and axle load of cars, has necessitated the strengthening of branch lines with heavier rail and stronger bridges; more ties to the rail; wider banks and cuts; ballast has had to be applied; with the result that the \$12,000 to \$15,000-branch now costs \$20,000 to \$30,000 per mile, with the increased interest charge on the investment and the increased tax on the public to be added to their taxes for good roads.

The cost per ton-mile for transporting freight and the cost per passenger-mile on the short branch lines are far more than the amount received by the railroad, the result being that the revenue from main-line business must be enough to pay for its cost, and in addition must be enough to cover the deficit on the operation of the branch lines. If, therefore, many of these lines that are tributary to a territory within the limits of auto-bus and auto-truck service could be taken up and abandoned, it would mean a reduction in the cost of main-line service.

On the other hand, on such branch lines as cannot be replaced with motor service and do not connect with or cross other railroads, there should be a rate that would yield an amount sufficient to cover cost of upkeep and operation, and to pay the required return on the value of the line, as by this means the main-line rates could be reduced.

Factors to Consider when Abandoning Branch Lines

In considering the question of abandoning a branch line, the first question that comes to the mind of the railroad man is the capital charge. The capital account would have to be credited with the book value of the line abandoned, and operation charged with the same less salvage, but this would be saved in direct outlay in a period of about five years and should be distributed over such a period.

After a careful survey of the situation on each railroad the use-

[1] Chief Engineer, Chicago, Rock Island and Pacific Railroad.

Abstract of paper presented at the Annual Meeting, New York, December 7 to 10, 1920, of The American Society of Mechanical Engineers. All papers are subject to revision.

less branch lines should be listed and a program made up to cover a period of five to seven years, at the end of which period they would all be up and charged to operation, and capital account on which the public must pay a return would be reduced that much, and in addition the public would be relieved of the cost of operation, maintenance and taxes on these lines.

Branch lines are a necessity and it should not be understood that any attempt is being made to belittle their importance, but the transformation that is constantly going on in large cities in connection with the suburban train service, by which stations near the center of the city are abandoned, due to rapid transit on elevated railroads or subways, furnishing as good or better facilities, is also taking place where short branch lines are being operated, where the business can be taken care of as well, if not better, by motor cars on hard-surfaced wagon roads.

The abandonment of short branch lines of railroad and the delivery of freight at main-line stations also means an increased use of cars, as a car sent to a branch-line station means, as a rule, a day going and a day returning to the main line, which is two car-days lost for each car, which will be saved if the car is loaded at a main-line station.

The abandonment of these branch lines will likewise do away with a lot of small mechanical terminals which are expensive to maintain, also with men employed as station agents and helpers on the branch lines, and it will increase the force at many main-line stations, where better supervision can be given to their work.

Tracks built to a single industry should be owned by the industry served and it should pay all cost of upkeep and all cost of operating. Tracks that lead to several industries should be limited to a single industrial track, which should be operated by one railroad, and all expense of upkeep and operation should be paid by the industries served by the line. Also less-than-carload freight should be collected for all railroads at the various stations in the city and should be taken to a central point by one railroad or terminal company, and there made up into carloads and billed over the railroads to which it is assigned. The cost of this service should be kept separate and added to the carload rate from the consolidation point. In short, those getting special services should pay for that service, and those who do not use the special service but perform a part of it themselves should not have to participate in the cost of this special service.

Rate Making as Affecting Branch Lines

In the effort to compel the reduction of rates, both the federal and state regulatory bodies have encouraged the idea that the heavy-traffic main lines were able to handle traffic so cheaply that they should absorb the losses due to rates being too low on the branches, and so in former times a differential rate often existed and branch lines had higher rates than main lines. Now, however, that it has been decided that the railroads shall have rates that will pay the cost of production of transportation, this cost should be allocated as far as possible and paid by those getting service. With the special service paid for separately it will permit of a reduced rate for main-line service from terminal to terminal, or from intermediate stations to terminals, which is what the vast majority of the people use.

A railroad line will, under present conditions, with the advent of the auto and truck, secure all of the business within 50 miles on either side. In the western portion of the country, however, there are large areas that are not within 50 miles of a railroad, where the quality of the land is just as good as that adjacent to the railroad, but which is not cultivated for lack of transportation facilities. The lack of return on investments in railroads during the past ten years has prevented these railroads from securing the money with which to develop the territory that naturally belonged to them, with the result that the cost per ton-mile has been much more over these lines than it would have been with a proper system of feeders. Some of the more prosperous railroads have systematically constructed feeder lines, and their prosperity under the adverse conditions was largely due to this policy having been carried out for a number of years previous to the strenuous years just preceding the war.

With the requirements of the Transportation Bill that the Interstate Commerce Commission shall pass upon all new extensions, railroads that have undeveloped territory adjacent to their lines which will warrant the construction of feeder lines and increase their main-line business, thus reducing the cost per ton-mile of all business over the main line, should apply to the Interstate Commerce Commission for authority to construct such lines and for a freight and passenger rate over the new lines that will pay the proper return on the investment and the cost of maintenance and operation of the line.

The Construction of Branch Lines

These new lines should be located on the best grade line that the country affords, but in the beginning heavy grades and sharp curvatures should be inserted where they will make a decided saving in first cost; second-hand rail and obsolete and non-standard switch stands, frogs, etc., on hand should be used; station buildings of as cheap a class as possible should be constructed, exemption from taxes for five years should be secured from counties through which such lines are to be built, and everything should be done that will decrease the first cost so that the rates can be made as low as possible while business is being developed along the new lines. Later, when the business has developed and earnings will permit, the class of structures can be improved, and should such a line eventually be extended and become a main line the heavy grades and sharp curvature can be taken out at comparatively small expense.

It has been the practice in many cases in the past to charge but a nominal freight rate on material for these lines and to make no charge for general expenses, interest during construction, services of general officers, etc. This should not be done in the future, for if these expenses are not charged to the new line they will have to be absorbed in the operating expenses of the parent line. Each branch line should carry all charges for labor and material used in connection with its construction.

The same methods should apply in the maintenance and operation of the branch lines: all labor, material and freight for use on a branch line should be charged to it. To follow this out properly there should be graduated prices on material so that if a poorer quality of material, such as ties, rail, fastenings, etc., was used on the branch, it would be charged a cheaper price for this material; the whole matter to be handled so that the branch line is charged with what it gets—no more or no less.

The Operation of Branch Lines

No through rates should be made from points on branch lines; the local rate should be applied to the junction with the main line and main-line rates applied to the shipment over the main line. Shipments from points on the branch lines to points beyond the junction will of course get the benefit of the lower main-line rate, and, as the branch-line mileage will usually be but a small percentage of total distance, will probably cost no more in the aggregate than they do under the present system.

In operating a feeder line constructed to develop the country, a mixed train up one day and back the next is all that should be furnished until business enough has developed to warrant additional service. With the regulation of railroads by the Interstate Commerce Commission this can be done but only if the Interstate Commerce Commission has full authority over rates, both interstate and intrastate.

It will also be necessary, in order to permit the Interstate Commerce Commission to handle the question of new lines and abandonment of old lines, to have all railroad charters issued as national rather than state charters, otherwise it will be impossible to abandon useless lines or to make rates over branch lines that will cover the cost of operation and maintenance and yield a proper return on the investment, as state commissions look at the matter from a local standpoint and will object to the abandonment of lines or increases in rates within their state; whereas transportation is a national problem and should be so handled.

Finally, we shall be unable to make these changes in the maintenance and operation of the railroads unless the Interstate Commerce Commission takes a broad view of the transportation situation and handles its regulation along economic lines as a national rather than local matter, and does not let local interests interfere with the carrying out of a broad national policy.

I cost and the most expensive item of cost in railway operation. What proportion of the total cost is represented by terminals and terminal yards is impossible to say, but a high official of one trunk line entering New York recently made the guess that perhaps the reproduction cost of their end and intermediate terminals, together with equipment, would be as much as all the remainder of the road with its equipment. On the average, does it seem unlikely that at least 30 per cent of the physical valuation of the railways in the United States would be represented by terminals and terminal yards? Any figures short of a detailed valuation must be a guess, though a guess based on experience.

To make a similar guess as to the cost of terminal operation would be more difficult and with perhaps a less accurate basis. There is no segregation of cost figures that will give a reliable estimate as to how much of the total expense of transportation is absorbed by the terminals as compared with that absorbed by train transportation on the open track. The ratio will obviously depend on the length of haul, being greater when the haul is between nearby points such as Philadelphia and New York and less when between Chicago and New York; but on the average can it be safely put as less than the estimated constructive cost ratio of 30 per cent?

Again, the writer would like to give figures as to such cost of final delivery, but conditions vary so much in different cities that no reliable statistics can be given. Several investigations have been made in New York and one established the figure of cost of trucking from the railway freight house to the consignee's warehouse as amounting to as much as 80 per cent of the whole railway charge for carriage from Buffalo or Pittsburgh to New York. Place any figures you like within reason as the part of the total railway charge that should be allocated to the cost of passing a car through a New York terminal yard and the unloading of the goods, and it is evident that it costs much more to handle a ton of freight through New York to the point of ultimate destination than it does to haul that same ton some 400 miles, including in the latter expense the cost incurred in handling the goods in the originating and intermediate terminal yards.

Fixing Terminal Charges

There was a time when this question of railway terminal charge was largely one of dispute between shipper and railway companies. At strongly competitive points the companies held rigorously to any special convenience of advantageous location that they might enjoy to the exclusion of other lines. Today we are entering upon a new era of railway economy. To a great extent competition is removed and there is established the base principle that rates must be not only geographically equitable, but should be so fixed by governmental authority as to give a minimum net return which is also substantially a maximum net return on physical valuation.

It is obvious that rates can be raised so high that the resultant gross returns will show declines and not increases. Managers must therefore see that rates are not carried beyond the critical point, or, to put it another way, they must see that business is conducted economically. But that responsibility is also placed on the shipper. If he would avoid further raises in rates he can aid by focusing public attention on the unnecessary burdens placed by legislation on transportation companies, on the failure of the transportation companies to use their properties in the best manner to produce the most economical results for all concerned, or on the failure of public authorities to coöperate with the transportation companies and with each other.

Let us briefly consider terminals and terminal yards from this point of view. The capital invested is probably 30 per cent of all railway capital, and the cost of operation is perhaps as high a terminal operation, therefore, will result in a sensible reduction in operating expense, which reduction inures first to the benefit of the shipper and only to the benefit of the company when an increase in rates no longer produces an increase in gross returns.

How can savings in terminal expense be obtained? In the old competitive days it was necessary for each company to have its own complete terminals and to prevent competitors from obtaining facilities as ample or so well located. There resulted, consequently, as many terminal yards as there were companies, and frequently each terminal yard had its own separate arrangement for the handling of every class of commodity. Under the present law the systems are not actually combined, nevertheless the cutthroat competition has been removed, and the companies are not only free but are encouraged to eliminate wasteful duplication. The Chicago Terminal Commission has already answered this question by saying that "there are decided advantages in coöperative operation."

In 1918 the railways in different parts of the country began to put such coöperative operation in effect and reports show that savings of very measurable proportions resulted. In the northwestern, central-western and southwestern sections covering twenty-eight states, estimated annual savings amounting to $5,750,000 have already been obtained. Would there not be really great savings if all the terminal facilities in all our cities should be pooled and duplication be avoided?

The Cost of Terminal Operation

How can terminals be more economically operated is another question. Many of our terminals, especially passenger, are seriously overburdened, and yet on account of surrounding urban development the facilities cannot be increased. The commuter seeing our great stations crowded morning and evening does not realize that during the remaining twenty hours the efficiency is gradually reduced to zero, giving a very low average load factor. Would electric operation result in simplification and economy? At end terminals with electric equipment, local or suburban trains which constitute the great majority of passenger trains could be handled in and out and do their own switching without calling for shifting engines. Between end terminals the engine runs could be lengthened to any reasonable degree. The electric locomotive, unlike his steam brother, does not have to be taken to a roundhouse after a limited performance.

The question has been put, "What can the railways do to reduce the cost of terminal operation?" The complement question can also be put, "What can the shippers do?" A few years ago shippers used both railway freight houses and cars as places of free storage for long and indefinite periods. High demurrage charges rigorously enforced, however, have greatly reduced this irregular and wasteful proceeding, and in fairness to all parties it should be stopped entirely. There is perhaps only one way in which this can be done and that is by having the railway companies do all the unloading and delivery, either by their own agencies or by some authorized single agent acting for them. To cover the cost of this delivery service, freight rates would have to be raised correspondingly, but the total would be much less than the present cost to shippers, which is a combination of the railway charge and their own trucking expense.

New York Terminals a National Question

At a meeting in New York where terminals are being discussed one cannot refrain from speaking of New York's terminals, nor is it proper to refrain because New York's terminals are really the affair of the whole country. In what can be called the Metropolitan District, embracing a part of New Jersey as well as the City of New York, there is located nearly one-twelfth of the whole population of the United States, and this same district is the greatest manufacturing center of the United States. Forty per cent of the export and import traffic of the whole country passes through the port.

Abstract of paper presented at the Annual Meeting, New York, December 7 to 10, 1920, of The American Society of Mechanical Engineers. All papers are subject to revision.

Fuel and Its Conservation

A Group of Papers Dealing with The Fuel Supply of the World, Fuel Conservation, Distillation of Fuels, and Form Value of Energy, with Discussion Thereon, Which Were Presented at the 1920 Annual Meeting of the A.S.M.E.

ONE of the most notable features of the 1920 Annual Meeting of The American Society of Mechanical Engineers was the interest aroused in the sessions devoted to fuel and its conservation. These were held under the auspices of the newly formed Professional Section on Fuels, and in order that all might have an opportunity to express their views concerning this most vital question, two adjourned sessions were necessary. The papers presented were by L. P. Breckenridge who spoke on the Fuel Supply of the World; David Moffat Myers, on Fuel Conservation; O. P. Hood, on Distillation of Fuels as Applied to Coal and Lignite; and Messrs. C. G. Gilbert and J. E. Pogue, on Form Value of Energy in Relation to Its Production, Transportation and Application. Abstracts of all of these papers are presented below, as well as an account of the discussion which they brought forth.

THE FUEL SUPPLY OF THE WORLD

By L. P. BRECKENRIDGE,[1] NEW HAVEN, CONN.

FOOD and fuel are basic necessities of our present-day existence. Here in America as recently as one hundred years ago men were selecting a place to live where food could easily be produced and where wood was nearby for fuel and for the building of the home itself. Up to 1820 fuel was needed primarily for cooking food and for keeping warm. At that time power was produced by wind for the sailing vessels and by falling water for the grist mill, sawmill, cotton mill, woolen mill, and forge. The total amount of coal mined in the United States up to the end of the year 1840 was only 12,000,000 tons, an amount which is now produced in six working days. In fact, the total coal mined up to the end of 1880 was not more than 1,000,000,000 tons, an amount now produced in twenty months.

Fifty years ago the total coal production of the United States was less than one ton per capita (0.96 ton). Today it is slightly over 6 tons. This great increase is accounted for primarily by our growth as a manufacturing nation, involving great increases in the requirements for transportation, but to this must be added the evident fact that we have surrounded ourselves with many comforts, then unknown, as well as luxuries which still are never found in many foreign countries.

We are rich indeed in fuel, but our wealth of fuel resources should not make us wasteful of these resources which are a world need and which, when once used, may never be replaced. It is hoped that a study of the facts presented in Tables 1 to 7 will serve to emphasize the larger problems of fuel as related to their place of production, extent of exhaustion, methods of transportation and especially their methods of use, pointing—as all the facts do—to the great necessity for coöperation for conservation.

The time has come when the fuel problems of the world must be given consideration in a large way. Communication and transportation have made all countries of the world near neighbors. Food and fuel are essential to the world's life and progress. The United States now for the first time has cargo vessels. It will fail in its duty if it does not make wise use of its resources and its facilities to aid the people of the world.

The title of each of the tables given is sufficient to indicate its import. War conditions have made many temporary disturbances in statistics of this character, and for this reason it has seemed wise in some cases to choose prewar conditions where it is simply the trend of progress that it is desired to indicate.

A Plea for Thrift and Conservation

The difficulty of securing a supply of coal coupled with the high price paid for it, has in itself brought about a desire to exercise all possible care in its use. The public at large more and more realizes the need of coöperation to secure conservation in some large way. It is in connection with the last plan, "coöperation for conservation" rather than on "individual thrift" that the writer sees the most promising chance for initial success. Especially is this true as a wise first step. Individual thrift should always be practiced, but the large savings of fuel that could be made by coöperation are way beyond anything that could be expected from individual effort. The suggestions for coal conservation which follow are not new—some of them are already begun—but it is only when all of them are fully realized that we shall be able to feel that we are really making satisfactory progress in preventing waste of fuel, as well as waste in labor and capital, which are required to produce and transport it.

How to Prevent Waste of Coal

1 Extend as rapidly as possible improved methods of mining coal. Under present conditions, one-third the bituminous and one-half the anthracite coal is left in the mine under such conditions that recovery is practically impossible.

2 Extend improved methods of "preparation" of coal at the mines. A premium might well be allowed for well-prepared coal, or a penalty imposed for impure coal.

3 Reduce the hazards of coal mining. For every 1,000,000 tons of coal mined there are between four and five fatalities.

4 Operate the mines a maximum number of days each year. Mines are operated from 200 to 240 days in one year. Lost time is due to three principal causes: shortage of cars, shortage of labor or strikes, and mine disability.

5 Utilize a larger amount of the mine waste. Briquetted fuel, pulverized fuel and electricity from mine waste are all possible of successful development.

6 Increase the use of by-product coke ovens. The by-products wasted by beehive coking are equal to fully 600 lb. of coal per ton of coke produced. Increase the use of domestic coke from the local gas plant.

7 Extend the use of blast-furnace gas for power generation. Much progress has recently been made. It will require coöperative effort to utilize fully the power which might be made from blast-furnace gas.

8 Extend the use of the gas producer, the gas engine and the heavy-oil engine for power generation, more especially where electrical energy is not available. Develop the lignite fields—by power from gas producers—and briquetted fuel for domestic use.

9 Extend water-power development. Hydroelectric power often combined with steam power offers large possibilities for saving coal. It will require comprehensive expert study before any new development can be undertaken, or satisfactory financial returns may not be possible.

10 Extend very generally the best-known performance of locomotives. The better locomotives of 1920 use only two-thirds of the coal required 20 years ago to do the same work. Much saving should be expected in the operation of steam locomotives. Electrification will save coal where water power is conveniently available. Instructions to firemen should be given and followed up even more carefully than in the past.

11 Encourage the tendency of the small industrial plant to purchase its power. The best coal is often sent to the small plant. Small plants, like individuals, should be examined by experts and all reasonable effort made to conserve fuel. Correct equipment and correct methods of operation would save 20 to 25 per cent of the coal used in industrial plants. It is the coal saved by the industries that will set free transportation facilities sorely needed for other purposes than hauling coal. One-third of the railroad tonnage is coal.

13 Extend the custom of coal storage. The facts relating to this important practice are now available. Coal may be safely stored and the load curve on the mining industry may be much improved. The coal should be stored at or near its point of consumption.

14 Extend electrification. The full use of electrical energy offers the most promising means of saving coal. Conservation by coöperation of water power, steam power and electricity opens up large possibilities for saving coal, capital and labor. This is contemplated by the superpower plan now being investigated by the Department of the Interior and a report is in preparation by an engineering staff which will set forth the facts as to: (*a*) Needs for superpower, (*b*) characteristics of an installation, (*c*) location of suitable superpower lines, (*d*) estimated costs, (*e*) estimated economies and other details.

DISTILLATION OF FUELS AS APPLIED TO COAL AND LIGNITE

By O. P. HOOD,[1] WASHINGTON, D. C.

Much has been written on the subject of the distillation of coal, covering the field from the intricate chemical reactions involved to the economic aspects having a bearing on statecraft. The subject is by no means new since men of perception have for many years pointed out the fact that coal is a raw material from which many values other than the heat of direct combustion can be obtained.

The growing appreciation of these values by the layman as a result of present writing is, however, new. There is a widespread feeling that we are not wise in our present methods of using coal. It is well to awaken general interest in this subject, and presenting the matter in exaggerated form to more quickly convey an impression is somewhat justifiable, but it is quite possible to overdo the matter. When coal is used raw for heat generation it should always be with a proper understanding that this material might, under more favorable circumstances, be used for higher purposes. Beside major products of coke, gas, and pitch, an alluring chain of oils, dyes, and medicinals might have been produced.

While all this is possible it does not warrant the conclusion that all coal should be made to yield the last-mentioned products. Because wheat can be made into cake the market for bread is not to disappear. There will always be much use for raw coal, for in this form the individual has the disposition of a maximum amount of energy with the least fixed liability. It must be recognized,

---

[1] Chief Mechanical Engineer, U. S. Bureau of Mines, Mem.Am.Soc.M.E.

Abstract of a paper presented at the Annual Meeting, New York, December 7 to 10, 1920, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. All papers are subject to revision.

therefore, that the distillation of coal is not for universal application, but that it will find its appropriate field of usefulness together with other and cruder methods.

The layman is likely to overlook the fact that processing of coal to obtain more than one or two products is necessarily a large enterprise and not to be entered into with small means or on a limited scale. Even on a large scale the tendency has been to look to a single product to justify the installation; e.g., in the production of metallurgical coke the gas has been wasted, and in the production of city gas the disposal of coke was a problem.

The investment required in large plants for coal processing is so great that it is no reproach to forego this form of ultimate economy so long as our savings are more needed for development in other directions. In other words, conservation of capital is as necessary as conservation of raw material.

There are, however, rapidly developing fields in which the processing of coal is extremely desirable and is practicable. These fields are made apparent by the greatly increased cost of coal, by a general realization that there is a limit to easily won high-grade coal, by the decline of natural-gas supply, the increased cost of transportation, and a growing appreciation of and dependence upon fluid fuels, both gas and oil.

There is a popular hope that if elements of higher value are recovered from coal by distillation, the remaining fixed carbon can be sold at a price lower than the raw fuel; in other words, that coke as a domestic fuel can be sold at a cheap price. Where in any process a chain of products is produced, the actual cost of production of each is largely a matter of bookkeeping and each is priced at what the market will bear. So far, the market has absorbed coke at a price which leaves little hope for cheap fuel from this source and it is not likely that processed coal can yield cheap fuel. It is more likely to produce a fuel whose special qualities of cleanliness and smokelessness will command a good price and supplement our declining store of anthracite coal. There is also the hope that by extensive distillation and other processes manufactured gas may reinforce our rapidly disappearing natural gas. There is little to justify the hope that relative prices for heat units in the form of gas can ever again be as low as they have been in the case of natural gas, for it is now recognized that even natural gas has been sold too cheaply to return the investment at the end of the producing period.

Processes of Distillation

The fact that motor and other oils can be obtained from coal distillates and that there is a market for all that can be produced, strengthens the position of distillation processes. There is a growing appreciation of the fact that the character of coal distillates is quite as much a factor of the process as of the coal used. The amount and quality of the distillates is determined by the heat experience of the primary complex constituents of the coal, so that variation in the engineering structure and mechanism of the apparatus, together with temperature treatment, gives opportunity for a variety of processes and results. These processes can, therefore, within limits, be fitted to the major products desired. A great deal of attention has been given to distillation resulting from temperatures not exceeding about 1400 deg. fahr., which are lower than used in coke-oven or gas-retort distillation. Prof. S. W. Parr states that "in general, it is believed that all the products of decomposition have a higher intrinsic value as delivered under low-temperature conditions chiefly because excessive secondary decompositions are avoided." With the usual methods and lower temperatures there will be considerable difficulty in transmitting heat to coal at a sufficient rate to obtain reasonable capacities from a given investment and in this particular low-temperature distillation is at a great disadvantage, which must be equalized by a greater refinement of its products. It is therefore hard to see how low-temperature distillation can be expected to yield a cheap fuel.

Distillation of coal in by-product coke ovens is already the major process in the production of metallurgical coke, and in a few years probably only the peak load of productive years will be carried by beehive ovens. The gas produced is used in the adjacent industries which determine the location of the plant, and much of the tar is burned instead of fuel oil. An appreciable addition to the supply of motor fuels is made by the benzol which is recovered, and ammonium sulphate for use as fertilizer is recovered in quantity.

A return to distillation methods in the city gas industry is indicated now that gas oil is no longer cheap for the enrichment of water gas and an outlet for coke in domestic heating service becomes more assured. This is the most favorable field for the expansion of distillation processes.

There is great need for a high-class domestic fuel in the lignite areas of the United States where there are large supplies of low-grade fuel. The increased difficulties and cost of transportation of eastern coals into these districts makes the problem a specially urgent one. Experimental work has shown the possibility of applying distillation methods to lignite, obtaining gas, tar, ammonium sulphate and a carbonized residue of excellent heating value. In most regions where this need exists the solid fuel would be the main objective of the process, possibly wasting the others. The char is too fine for domestic use without briquetting, but when put in proper form it makes a fuel comparable with anthracite.

In the southern lignite area there is also a need of developing a distillation process which will make lignite available for the production of city gas. This seems quite possible from the indications of laboratory work, but in both of these fields there is no commercial development. It seems as though the laboratory and small-sized experimental plant had contributed about all that it could and the business awaits that longer step which must be taken to realize these results in full-sized apparatus. In fact, many fuel-distilling processes seem to have reached this interesting stage of expectancy.

FUEL CONSERVATION

By DAVID MOFFAT MYERS,[1] NEW YORK, N. Y.

Seventy-five to one hundred million tons of coal per year could be saved by the adoption in the United States of well-known and well-tried methods of fuel conservation, and this saving would be in addition to a similar reduction in the consumption of other fuels. The writer's experience in the Fuel Engineering Section of the United States Fuel Administration demonstrated without possible doubt that such conservation would involve no experimental features, and that it could be readily accomplished by the simple adoption of sound engineering principles in the use of fuel by consumers. Prevention of waste is merely a matter of the application of well-known engineering principles.

Based upon only 75,000,000 tons, the money saving would be $450,000,000 per year, or enough to pay nearly one-half the interest of our national war debt.

The transportation of coal would be relieved to an extent equivalent to a million and a half 50-ton carloads per year, or 50 per cent more than the coal-carrying capacity of the Pennsylvania Railroad lines east of Pittsburgh. The significance of this will be realized when it is stated that the chief difficulty in securing coal today is due to lack of transportation facilities.

The services of 75,000 miners would be conserved, so that the same force would be able to handle the natural increase in mining production. The additional labor connected with the loading, transportation, and unloading and firing of a million and a half less cars of coal per year would also be eliminated.

Fuel conservation is good for other countries, as it enables us to do our part in supplying their markets. It should be emphasized at this point that the kind of conservation which the writer has in mind is "constructive conservation," which means using fuel efficiently without reduction in the output of our manufactured products and without the slowing down of any of the natural phases of our national and social life. It is necessary to inject this statement owing to the fact that during the war "destructive conservation" was also largely practiced, which simply mean the cutting-off of coal supply to various industries and uses with the consequent impoverishment of our industrial and social life.

All consumers of coal would benefit financially by a program of constructive conservation. During the war, by the adoption of

[1] Consulting Engineer, Griggs and Myers, Mem.Am Soc.M.E.

Abstract of a paper presented at the Annual Meeting, New York, December 7 to 10, 1920, of The American Society of Mechanical Engineers. All papers are subject to revision.

It was impossible, at that time, owing to conditions imposed by the war, to adopt measures affecting also the design or equipment connected with the use of fuel. A future program should include such measures. The efficiency of any process that is connected with fuel or any other material is equal to the efficiency of the operation multiplied by the efficiency of the equipment. In other words, the man multiplied by the machine.

The Waste of Fuel in the United States

There is at present a huge and unnecessary waste of fuel in this country. The waste is everywhere. There is not an industrial plant in the country where 10 to 30 per cent saving of fuel might not be effected by common-sense engineering. Some of the items relating to this waste are as follows:

(1) Waste in the boiler plant, including the very large item of inefficient combustion of fuel under stationary and locomotive boilers. Sixty-seven per cent of all the coal mined in this country is consumed for the purpose of making steam on land.

(2) Coal consumed in the old-fashioned, wasteful beehive coke ovens represents 9.3 per cent of the total. Only 4.3 per cent is consumed in the by-product coke ovens.

(3) In domestic heating it is estimated that 12 per cent, of the coal is used. Very large savings were made in this department during the war, and much more can be done by proper conservation methods. The psychological importance of emphasizing fuel economy in this field is evident owing to the fact that it would deal with 20,000,000 people or householders, whereas by comparison fuel conservation in the industries would deal with only 200,000 plant managements and those of the railroads.

(4) Fuel is extravagantly wasted by improper use of steam after its generation. For instance, by the use of:

(*a*) Inefficient types of prime movers
(*b*) Careless maintenance of power-consuming machinery
(*c*) Ill-advised installations unsuited to the purpose they would fulfil
(*d*) Huge volumes of wasted exhaust steam expelled to the atmosphere or to condensers, and live steam used for heating without first developing its quota of energy
(*e*) Unnecessary use of live steam where exhaust steam with proper engineering would fully meet the requirements
(*f*) Badly designed and ill-kept transmission systems.

Of these forms of waste item (*d*) needs the greatest emphasis. Everyone knows steam is being wasted when they see clouds of exhaust blowing out into the air, but how many people (not engineers) realize that our modern and highly efficient central stations are guilty of wasting some 80 per cent of the heat of the steam into the condenser, while at the same time, particularly during the heating season, hundreds of buildings and factories in the vicinity are burning thousands upon thousands of tons of coal for heating purposes, and that the owners of these would gladly dispense with their expensive heating plants if the central station would sell them heat as well as power.

Fuel Savings in Industrial and Private Plants

The other side of the problem relates to the private plants, each of which must be diagnosed according to the merits of the case. Many industrial plants can utilize all of the exhaust steam from their own power plants all the year round, and in such cases their power is merely a by-product of their heating fuel. If they were to shut down their engines or turbines they would still have to burn about 90 per cent of their former coal consumption, so that only 10 per cent of their engine water rate is chargeable to power. Such a plant of course produces its own power so cheaply that no central-station condensing power plant will ever be able to compete with it. Frequently it would easily be able to generate more power than it can use without wasting any exhaust steam, under which circumstances it should be enabled to sell its surplus power to a central-station system.

The other extreme exists when the private plant has no use for heat and wastes all of its exhaust to the atmosphere. Coal, and ments were sufficiently large, could afford to install modern equipment and make its own power more cheaply than it could buy it. Coal might not be saved over the plan of buying power from the central station, but money would. A very common case is that of the private plant that can utilize all of its exhaust heat during the heating months but wastes it through the non-heating months. Such a plant should make its own power in cold weather and buy it in warm weather. What we need to develop is a flexible plan of coöperation between the central power stations and the privately owned plants.

The superpower system advocated by W. S. Murray, apparently fails to consider the vital factor of industrial and building heating, and unless this factor is interwoven in the system in the manner the writer has indicated above, the waste of steam and fuel (to the condenser) in large central stations would be augmented rather than reduced. If power alone were the only consideration necessary, Mr. Murray's plan would avoid this important fault. As applied to the railroads alone, which consume 28 per cent of all the coal we produce, the plan would appear to have many important advantages.

Our Failing Supply of Fuel

The need of a definite policy of fuel conservation is urgent. Natural gas, the most nearly ideal of all our natural fuels, today is practically gone. Inside of three years there will be no more available for industrial uses, and all owing to our failure to demand a definite policy of conservation. We permitted instead a definite policy of waste.

The next natural fuel to go will be oil. The supply in the United States it is estimated will be used and wasted out of existence in 20 to 30 years. Our production is stated at one million barrels of crude oil a day, which is more than 60 per cent of the world's total output, but this is not enough for our present domestic consumption. The peak of production will be reached in a very few years, whereas the consumption is increasing steadily. The demand for motor fuels is the greatest of all the items of consumption, and fuel oils is said to be the next largest. A bill has been introduced for an appropriation of $250,000 to enable the Department of Agriculture to conduct experiments looking toward the discovery of a new motor fuel. Coal-tar products including benzol are under consideration as well as alcohol. That the expensive method of producing oil from the shale beds of Utah, Colorado, Wyoming, and Nevada is being more and more brought to the attention of investors, is an indication of the urgency of the oil situation. All this is occurring years earlier than should have been, owing once more to our lack of a definite policy of fuel conservation.

We formerly had no policy whatever in regard to utilization of the vast water powers of this country. The economic waste that existed under these conditions was such that we were eventually forced to adopt a definite policy, as illustrated in the recent Water Power Bill. This aims to protect the rights of future generations in this great natural resource.

Government Aid in Conservation

It is now the time to consider how the Government can assist in the conservation of coal and oil. It is the writer's personal opinion that coal and other natural fuels present a problem that so intimately concerns the welfare of all the people that it must equally concern the Government which represents the people, and that therefore until the general public through its Government takes action in the matter there can never be any truly adequate answer to this problem. The mere financial incentive to stop the unnecessary waste of fuel is not strong enough to do the job, for the reason that the great bulk of coal and other fuels is consumed in industrial undertakings, wherein substantial profits are readily available without the trouble of economizing in the application of fuel. This fact may be strikingly realized through the statement of an authority that of the total cost of all the manufactured products of the country only 2 per cent is fuel cost.

The public at large does not yet fully realize the importance of fuel as a national issue, but the writer believes that even now it is coming slowly into such a realization. Therefore, although the time is not yet ripe for any radical step in this direction, yet we may and must look forward ultimately to a solution along these lines.

The public must be made to see how adversely it is affected by this great and uncontrolled waste of fuel so that Government coöperation and assistance will be demanded. This means that time will be necessary in which to educate the public as to the importance of fuel conservation as a national issue in order to secure the necessary interest by Congress and Government bureaus.

Finally, the writer wishes to offer for consideration and constructive criticism the following policy of fuel conservation to be adopted with the coöperation of the Government:

(1) Regulation of quality of fuel.

(2) Measures for prevention of flagrant waste of all fuels.

(3) In the matter of transportation, zoning is productive of large economies.

(4) Better means of coal storage are urgently needed to flatten out load curves at the mines, which are now overcapitalized and overequipped 40 per cent.

(5) Possibilities of conservation by the United States Bureau of Mines.

(6) Great advantages to be secured by appointment of a resident engineer in each state, to keep in close touch with local industries and with a clearing house of information in Washington.

(7) A body of citizens advisory to Bureau of Mines should assist in the planning and development of the conservation program. It should be representative of business men, engineers, and citizens from various parts of the country.

(8) Correct design of new power plants, and perhaps changing of power equipment in existing power plants.

(9) Government should encourage new inventions and investigation, leading to the economical use of fuel.

(10) Better educational measures. Every technical school should have lecture courses on fuel conservation, more for the purpose of emphasizing its importance rather than from intensified and specific instruction. Educational courses for chief engineers and firemen. Examination for license in this profession. Provide throughout the country uniform examinations with corresponding certificates for operating engineers and firemen thus educated in steam and fuel and economics.

(11) Measures looking toward the development of low-temperature distillation of coal (and lignite) for the conservation of the immensely valuable by-products which at present are wasted when raw coal is burned for steam making. The resulting smokeless carbonized coal would then become the boiler fuel of the future in proportion to the extent to which this by-product industry could be economically developed.

FORM VALUE OF ENERGY IN RELATION TO ITS PRODUCTION, TRANSPORTATION, AND APPLICATION

By CHESTER G. GILBERT,[1] WASHINGTON, D. C., and JOSEPH E. POGUE,[2] NEW YORK, N. Y.

Coal, oil,[3] and water power are the principal sources of energy in the United States. Although commonly regarded separately, they really constitute a single resource group which provides the energy essential to modern conditions and contributes commodities of growing importance besides. Two-thirds of the energy extracted is consumed as power in doing the work of industry and transportation, while the remainder is devoted to the production of heat and light, and the furtherance of chemical work. The commodity values held in coal and oil, while having an important and growing bearing upon modern needs, are largely ignored. Not only is the civic and industrial life of this country utterly dependent upon the energy materials, but the production, transportation, and distribution of these essentials constitute a prominent aspect of the country's activities.

Can this country continue to rely almost exclusively upon the railways for its supply of energy? Coal alone now engages nearly half the freight capacity of the railways. Can the cities and homes of the country afford to turn to bituminous coal with its smoke and dirt for their fuel dependency? Anthracite is fast becoming a luxury and metallurgical coke is not a satisfactory substitute. Is the public ready to curtail the use of automobiles and motor transport within the next few years because of an inadequacy of gasoline? The petroleum resource is already showing signs of strain. Is it wise for this country to ignore its water-power resources? Under present conditions water-power sites, with choice exceptions, cannot be developed. If we are prepared to answer these questions in the affirmative the whole matter may be dismissed. Otherwise, the present situation must come up for revision.

These are the most immediate points of practical contact with the energy problem. They all involve issues of the day: transportation, domestic fuel, motor fuel, water power. But these are not all. What of the congestion in our terminals and cities because of coal distribution and ash removal? What are the civic losses due to smoke? What of the values going to waste when raw coal is burned? Can these be saved and made to contribute to a lowered fuel cost? What are the chances of building up a large coal-products industry in this country? Has chemistry as yet wrested its full count from coal tar? What shall we miss by not cultivating this field? Can coal solve our nitrogen problem? What are the by-product possibilities in petroleum?

These questions are pressing forward for attention. They involve the foundations upon which our industrial stability, our domestic comfort, and our national welfare are based. With bountiful resource wealth and with mastery of technology we have proved ourselves to be lacking in adequate economic procedure to take advantage of our endowment. The conditions under which energy is brought into play in the United States are mainly an inheritance from a period when the character of energy resources was imperfectly known and the technology of energy employment was crudely developed.

The employment of our available resource in energy involves three progressive stages: production, transportation, and utilization. It may be of interest to examine coal, oil, and water power in turn with respect to their status under these headings.

Coal

The production of coal is scattered, uncoördinated, and wasteful. The coal mines of the country carry a variable but large idle capacity, accompanied by an uncertainty of operations, that is at once a menace to the stability of the labor supply and to the maintenance of an adequate output; the technique and practice of storing coal is imperfectly developed; the seasonal fluctuations in the demand for coal remain uncompensated. These conditions are essentially the product of past circumstances—excessive competition, overdevelopment of the resource, and inadequate prices at the mine mouth, which led to poor engineering and low recoveries of values.

Transportation is the weakest link in our coal supply. Coal forms over a third of the country's freight; the mining of coal is dependent upon an unbroken movement of coal cars past the mine mouths; the number of coal cars has never been equal to the full capacity of the developed coal mines. With every period of industrial prosperity, a car shortage is bound to result. Moreover, as a result of the size and industrial status of this country, the railways have a sufficient responsibility without the carriage of coal.

Present utilization of coal involves a very low recovery of the energy content and an almost total loss of the commodity values present. This of course necessitates the production, transportation, and distribution of a much larger quantity than would otherwise be required; concentrates the whole cost, in respect to the consumer, upon the modicum of energy extracted; requires the imports of materials which might be manufactured from the non-energy components; holds back the development of latent possibilities

[3] In an economic sense, natural gas may be regarded as a variant of oil and needs no separate consideration in this summary paper, since the principles governing the production, transportation and utilization of both oil and natural gas are similar.

Abstract of a paper presented at the Annual Meeting, New York, December 7 to 10, 1920, of The American Society of Mechanical Engineers. All papers are subject to revision.

waste than is found in the mining of coal, with far more serious consequences because the domestic supply is altogether inadequate for meeting the present requirements of the country and the domestic resource is rapidly suffering depletion. Less than half of the oil underground is raised to the surface; there has long been an overproduction in respect to the higher types of uses, prompting the surplus to be used for crude purposes in the place of coal and water power.

The transportation of petroleum makes use of an extensive system of pipe lines, thousands of miles in length, spread over half of the country, connecting points of production with refineries, markets, and seaports. The efficiency attained in the transportation of petroleum energy is in marked contrast to that characteristic of coal energy, and should point the way to the reconstruction of the latter, whose faults are now throttling the commodity transportation of the country as well as contributing to unhealthy urbanization and sectionalization.

The utilization of petroleum is far in advance of coal in that the bulk of crude petroleum now produced is separated into its chief components—gasoline, kerosene, fuel oil, and lubricants—whereas coal is employed dominantly in the raw state. Here again the oil industry points to the analogous need for a coal-refining industry to separate coal into mobile forms of energy and commodities. The utilization of the various petroleum products displays various degrees of efficiency, with the greatest discount applying to the low-use products such as fuel oil. The by-product actualities held in petroleum are not yet adequately utilized, nor are the by-product potentialities sufficiently developed.

Water Power

Only a small fraction of the water-power resources of the country is developed. This is due to the abundance of coal and oil, on the one hand, and the high rate of interest demanded by capital in respect to hydroelectric developments, on the other, with complications growing out of public sentiment and legal restrictions regarding water-power rights under Federal control.

The transportation of hydroelectric power, so far as it is produced, is technically satisfactory. The lack of a common-carrier system for the transmission of electrical energy, however, contributes to the undevelopment of water-power sites by making it necessary for the generating project to provide its own transportation.

The utilization of electricity for power production and lighting has been more highly perfected than that of any other form of energy; the application of electricity has also been more efficiently developed than the production and transportation of this energy form, viewed in an economic sense. The status of electric application is a cause for congratulation in an energy situation fraught with shortcomings, but at the same time this development has exaggerated the lack of balance obtaining in the present state of development of the energy industry and invites further neglect of the other energy forms.

Technique of Energy Analysis

This brief review is sufficient to indicate that the various components of the energy situation have developed to different degrees of attainment, and with little relation of one to another. In an industrial age, energy, the basis of industry, has failed to become an integrated industry itself. The production of energy is still individualistic, corresponding to economic conditions of the past; industrial activities in general have evolved to an interlocking and coördinated whole; not so energy. With minor qualifications the field of energy has merely grown in size and the system of energy supply is now modern in proportions but ancient in structure.

The reconstruction of an economically and socially competent supply of energy is an issue of profound importance, which cannot be met by discordant attentions to its component parts. The greatest weakness in the present situation is the dissociated character of its growth; little can be accomplished by merely perfecting

short of the mark.

The technique of conducting an adequate survey of the problem of energy supply involves a fundamental consideration of "form value" and "resource value." Form value is an intangible quality denoting the broad applicability of the energy form in contrast to its theoretical thermal value as ordinarily expressed in B.t.u., and involving the consideration of transportation as well as of utilization. Resource value is an intangible quality expressing the availability of energy in terms of location and chemical character of its source, and involving the potentiality of chemical control for purposes of multiple production.

Form Value

The concept of form value is of sufficient importance to warrant further attention. The significance of form value has been admirably illustrated by a series of valuable charts prepared by the W. S. Rockwell Company, covering industrial heating operations. The complete paper reproduces a member of this series, showing the factors governing the selection of fuel for industrial heating

Comparative costs of the most commonly used forms of energy in terms of thermal value are also given in the complete paper and they clearly illustrate the fact that form value is of greater importance than thermal value as a decisive factor in energy selection, for otherwise no other form of energy could compete with bituminous coal and the chief elements of progress in energy supply thus far attained would be nullified. The importance of form value is so obvious that it is difficult to understand why it has been so universally neglected as a broad economic concept.

Form Value in Respect to Application

The applicability of energy involves not merely the utilization of energy, but the transportation of it as well; both considerations necessitate a coördinate view of the value of the energy form in respect to what the demand for energy requires. This concept leads to a study of form value relative to application as the initial step in the development of an energy supply.

As is well known, energy may be brought to the points of application in solid, liquid, gaseous, or non-substantial (electrical) form. Under each form there are varying degrees of energy concentration. The market for energy, as developed by the innumerable natural and artificial factors that have contributed to building the present range of requirements, demands all four forms in their numerous varieties.

Before we are in a position to consider adequately the transportation phase of the energy problem, therefore, we must first determine what will best serve the needs, having regard for the potentialities as well as the actualities, afforded not merely by one system of supply, such as the electrical, but by all other types as well. To impart a special impetus in any one direction is to retard developments in all others. We should bear in mind that expansion in any one form of energy automatically follows the development of appliances for transforming that energy into useful service and that electricity has outdistanced gas more by virtue of this fact than because of inherent superiorities.

The demand for energy is a composite of requirements varying regionally according to the prevailing industrial type, and locally according to the details of the application. Both regionally and locally considerable possibilities of correlation are present, especially as between the needs for industrial power, on the one hand, and the requirements for industrial and domestic heating, on the other; since the two types of demand are to a large degree complementary. On the whole, a difficult compromise will have to be reached between what the market at the moment desires, and what it may be educated to take.

Energy application in this country in point of development thus far is the composite result of promotion and advertising. We have electrical experts; powdered-coal enthusiasts; fuel-oil advocates; mechanical-stoker adherents; but no recognized court of appeal for an unbiased consideration of a given item. Detail

after detail of power or heating installation has been added to the country's total as a result of the particular hands to which the item happened to be assigned. The character of this development renders the quality of the demand singularly difficult of economic appraisal, since the point of view of the analysis itself is apt to be colored by the same historical precedence.

Form Value in Respect to Transportation

While the market is under appraisal, the transportation of energy will require consideration, since the form value with respect to application is not wholly independent of form value with respect to transportation, although the reverse relation is to a partial degree true. The energy market has thus far been dominated by the transportation facilities available, whereas there should be a give-and-take relation between the two.

The means for transporting energy, are, of course, cars for the solid and liquid forms, pipes for the liquid and gaseous forms, and wires for the electrical form. With these facilities in mind, an appraisal of energy transportation must have an eye both to the application of the energy at the points of use and the resource value at the points of origin. The prevalence of energy haulage in the solid form has not only reduced the efficiency of energy utilization but has lowered the resource value of the energy as well, not to mention the loss arising from competition with commodities in a congested railroad system. The means of transportation which have naturally developed, or which may be arbitrarily provided, should be studied not only with relation to the effect upon transportation itself, but with respect to their influence upon the efficiency which may be derived from the energy and the values which may be won from the resource. The transportation of energy by either pipes or wires tends to stimulate the enlargement of resource value through by-product recoveries, and the increase of form value through added efficiency in application. The proper balance between a system involving the use of cars, pipes, and wires is an ideal upon which sufficient information is lacking even to speculate, and chiefly because transportation has not been studied with due regard to form value and resource value.

Resource Value

Of the three major elements entering into the energy situation, resource value has suffered the greatest neglect, both by the circumstances of development as well as by current plans for reconstruction. One element of resource value—location—it is true has been overemphasized in the course of industrial development, with the result that we now have an unhealthy centralization and urbanization with an aggravation of sectional and class differences. The major element of resource value—chemical character—is only just now coming in for some degree of attention, although the interest in it is not usually carried through to the point where the interdependence of resource value, transportation, and form value becomes clearly illuminated. The chemical character of the resource raises the problem of chemical control for purposes of multiple production, in order that valuable materials occurring with the energy, as well as much of the energy itself, may be kept from going to waste. In other industries the only way in which advancing costs have been effectively met has been through multiple production and its better-known partner, mass production.[1] The main reason why energy prices have advanced so strongly is that in the absence of an energy industry there has been no chance for savings in these directions while producing costs have steadily increased. Energy will lose much in social potentiality if its resource value is not enhanced over that obtaining at the present time.

In fine, energy needs to be placed upon a sound industrial basis, and this requires that due consideration be given to all these factors that are studied as a matter of course in connection with the establishment and nature of a new industry. The need is for adjustments in energy form to the end that greater efficiency in utilization and transporation shall be obtained, and a full measure of resource value received.

[1] In an economic sense, mass production and multiple production are the same. Mass production is the mechanical equivalent of multiple production which involves the element of chemical control; in many industries the two become actually identical.

DISCUSSION AT FUEL SESSION

The oral discussion which followed the presentation of the papers on fuel was entered into by a large number, and that all might have an opportunity to express their views two adjourned sessions were necessary. One of these was held on Wednesday morning, the other on Thursday evening.

At the first session discussion was largely confined to Professor Breckenridge's paper on the Fuel Supply of the World, and that by David Moffat Myers on Fuel Conservation. The use of peat, oil shale, and coke as aids in fuel conservation was touched upon by many. George Otis Smith stated that in one area in western Colorado and in eastern Utah it has been estimated that there are about ten times as much shale as fluid petroleum. He also pointed out that the oil-shale industry could not be expected to develop as rapidly as the petroleum had done, as it involved a much larger expenditure per heat unit for human labor.

Edwin DeLany referred to a process of making fertilizer from peat and expressed the fear that the supply of peat would be used up long before it was in great demand as a fuel.

In connection with the coke industry, Frank H. Kneeland stated that while it requires the greatest coal consumption of any of the industries, it was possible, through the processes of distillation, to create a coal containing 35 per cent volatile and producing a residue of solid fuel containing 8 per cent volatile, which is practically the same as Pocahontas coal.

R. P. Bolton was the first to discuss the question from the standpoint of conservation. He referred to the saving made by shutting down small electric plants and using electrical energy from central stations. In one case, he stated, such procedure had resulted in a direct saving of 25,000 tons, and allowing for the coal used in the central station, a net saving of 15,100 tons.

H. M. Crane spoke at some length regarding the use of fuels in the automotive industry. He stated that the petroleum industry is attempting to obtain fuels suitable for small isolated plants and for use in automobiles. The conservation of such fuels, he declared, is dependent upon their proper use by the public.

Harrington Emerson confined his discussion to the saving to be effected by a study of locomotive fuels. The locomotives of the country, he stated, burn 140,000,000 tons of coal per year, and looking at railroads as concerns buying coal at wholesale and retailing it by the ton-mile and passenger-mile, they had lost, as a whole, during the year 1919 nearly $15 for every ton of fuel burned.

Horace C. Gardner called attention to the conservation to be effected by coöperation with the Government. The trouble, he said, was that we really have 49 governments and we must get the coöperation of all of them. He suggested that this was a problem for consideration by the newly created American Engineering Council.

Joseph Harrington was of the opinion that fuel conservation was a problem of applying the knowledge that we already have rather than attempting to develop new knowledge on the subject. He also stressed the importance of publicity and education.

W. C. Buell called attention to the fact that in the steel districts a great deal of work has been done on fuel conservation and that in one case of which he had knowledge a billet-heating furnace producing 70 tons per hr. was operated at a thermal efficiency of 60 to 63 per cent.

Gardner T. Voorhees discussed the question from the viewpoint of the large public-service and electric plants. He stated that a device might shortly be expected on the market which would take the heat from the steam which is now exhausted into the condenser and by using one pound of steam from the boiler furnish several pounds of steam at moderate pressure for heating purposes.

Prior to the adjournment of the morning session the chair announced that at a conference between the chairmen of the Professional Section on Power and the Professional Section on Fuel, it was decided that the activities of the Fuel Section should end in the steam pipes between the boiler and engine.

Discussion at the First Adjourned Session

At the first adjourned session discussion was opened by E. H. De Lany, who spoke of conservation and the possibilities of coöperation with the Government. Referring specifically to the con-

people and he also has rights which he enjoys in common with them.

C. S. Blake stated that conservation rested very largely with the owners of power plants and that it had been his experience since the war that many owners did not care to practice fuel economy. The country does not lack engineering skill to give advice in the economical use of fuel, he said, but the ratio of fuel cost to value of production was such a small percentage that it was hard to interest manufacturers in this much-needed economy. In order to bring about this conservation he urged that a system of education be carried on between The American Society of Mechanical Engineers and the fuel users and without Government force.

D. T. McLeod discussed the same question and at considerable length. Conservation, he said, should start at the mines, for present mining methods do not recover anything like the amount of coal that is possible. He also stressed the importance of conserving by-product coals. He concluded by relating some of his experiences with regard to operations at the mines, especially as to labor conditions and their effect upon production.

R. H. Kuss commented upon the need of information as to fuel economy. The Federal Government, he declared, was not prepared to give such assistance. A. G. Bailey also spoke of Government aid. We should have, he declared, every chamber of commerce helping to bring public opinion to bear on both city governments and public-service commissions.

R. P. Bolton referred to the great saving that could be made by conservation of the domestic supply. The heating of New York City, he said, involved the burning of 7,000,000 tons of coal a year. As a means of saving in the transportation of this coal he suggested that a system might be created by which the coal would be brought to the city through pipe lines similar to those in use in the oil industry. Two 14-in. pipes, he declared, should be sufficient.

H. H. Kimber spoke at some length regarding pulverized fuel and the many uses to which it has recently been put.

D. C. Buell offered two recommendations as to procedure for future meetings. The first of these was that the Society work out a form giving the proper value of the different items which an engineer must consider in studying the waste of fuel, and the second that the Society send a delegate to the annual meeting of the International Railway Fuel Association.

G. T. Pogue closed the discussion of the second session with the suggestion that the Fuel Section devote some attention to the economics of energy service.

Discussion at the Last Session

At the final adjourned session on Thursday evening E. H. De Lany opened the discussion by referring to the great need of educational work in fuel conservation, and said that in his opinion lectures on fuel conservation would be of great value. Loring Freed referred to the low-temperature carbonization of coal and suggested that the Society go on record as advocating a campaign of education to encourage the use of low-candle-power gas and low-B.t.u. gas.

George H. Sharpe, in discussing the division of work among the sub-committees that had been proposed to handle the question of fuel conservation, suggested that an engineering representative from the coal operators be placed on one of the sub-committees. If this were done, he said, he believed it might lead to the creation of plans whereby it would be possible to work the miners 250 or 275 days a year, with a resulting reduction in the cost of coal of somewhere between 30 and 35 per cent.

A. D. White suggested that a committee be appointed to formulate rules for the use of coal, similar to those now in use for the building of boilers. David Moffat Myers also commented upon what he termed " the code of conservation," and stated that while excellent results had been secured during the war by the use of plant, Government engineers should look over the plans and pass upon them so that they may conform to proper engineering economics and will not result in wasteful operation. The French Government, he stated, is doing this very thing.

George A. Orrok was of the opinion that the greatest offenders in the waste of coal are the householders who, he stated, waste 40 to 50 per cent of the coal they buy. The city of New York alone, he said, uses about seven million tons of coal annually for domestic purposes, and if some method could therefore be devised to educate the ordinary man in the use of coal, it would probably result in the saving of 30 to 40 million tons of coal every year.

Joseph F. Shadgen, speaking of conservation, stated that while education was exceedingly desirable, it was his experience that an appeal could best be made to a man by showing him that he was losing money. A. A. Adler said it was his belief that it would be impossible to educate the public into saving fuel by means of laws. He also spoke of the savings to be made by having houses properly designed and suggested that the architects be interested in the question of fuel economy.

E. Kilburn Scott referred to present methods of mining, and stated that he believed some commission should determine as to whether in the interest of economy the long-wall system could not be employed in this country much more than it is. In reference to Government coöperation for fuel economy, he urged that consideration be given to a closer coöperation with municipalities. In England, he stated, there is a conservation officer just as there is a health officer, and his job is to see that there is no waste and to issue printed matter to educate the public in the proper use of coal.

R. P. Bolton differed from the previous speaker and gave it as his opinion that the first class to be educated were Government officials and municipal authorities. He also referred to the question of economy in the individual homes of the people and stated that if the tenants in our large apartments had to pay for the steam they used, a very great difference in the amount of fuel burned would be seen.

M. S. Hutton suggested that if the newly formed Fuel Section should create a committee upon conservation, it should coöperate with the Federated American Engineering Societies, as under this larger organization any work that might be done would carry great prestige and weight.

F. R. Low told of the objections that were offered to the Boiler Code when it was first presented by the Society, and how little by little, as states began to adopt it, the owners of boilers had accepted it as a standard. This was so because boiler explosions were communal disasters. Similarly, he declared, the wilful and unnecessary waste of fuel is a communal loss. Fuel conservation, he asserted, is a question of educating the individual and not of the passage of laws. "Cannot we impress these things upon the public," he said, "to an extent which will be fully as effective as a law which says 'Thou shalt not?'"

Elias Schlank closed the oral discussion by suggesting possible ways in which this education might be accomplished. Among other things he urged that the engineer take a larger part in civic affairs and that the children in the schools be taught the need and necessity of conservation.

Written Discussion

John W. Lieb, Jr., presented an extended discussion on the fuel problem in connection with the operation of public utilities, which use approximately ten to twelve per cent of the total bituminous production in this country. He said that whereas in 1916 the average price of good quality bituminous was roughly three dollars per ton f.o.b. tidewater, New York, of which about one-half was the charge for freight, at the present time the freight alone amounts to more than three dollars a ton. Apart from the price, however, it had been impossible during the past two or three years to obtain from coal operators a contract which, from a legal or commercial standpoint, is either reasonable or equitable. In fact, the "terms

and conditions" of the contracts, examples of which Mr. Lieb submitted, were such that they become at the pleasure of an unscrupulous operator practically a "scrap of paper," of little binding value.

Before the World War, said Mr. Lieb, there was sharp competition in the bituminous market and it is probably true that the competitive prices were too low and did not afford sufficient return on the investment. It was then possible to buy coal under a specification which assured its quality and would guarantee a certain number of B.t.u.'s per lb. within commercial limits, and a specified percentage of volatile matter, ash, degree of fusibility, etc. It was thus possible to gage boiler performance accurately and to obtain good boiler-room efficiency. All this has gone by the board. No specifications of any kind are obtainable at present. The boiler-room engineer cannot tell from one hour to the next what kind of coal is coming down on to the boiler-room floor or into the stoker hoppers. It has been a not infrequent experience to receive coal so deficient in quality that only 75 or 80 per cent of the maximum capacity of the boilers has been obtainable and station operators have been seriously concerned to meet the demands made upon them by their customers. Under these conditions, the speaker contended, the economic efficiency of utility plants (lb. of coal per kw-hr.) during the past two years cannot be taken as a fair or correct index of their normal and real economic efficiency.

Mr. Lieb then reviewed the history of the coal situation during the period of the war and subsequent to it, referring to the establishment of the Tidewater Coal Exchange, the restrictive orders under the Garfield Fuel Administration, the strike of bituminous coal miners in 1919, provisions for priority shipments, etc. He said that while the New York Edison Company had withdrawn from the New York Tidewater Exchange because it was unable through the Exchange to receive the specific coal which it had bought, the Exchange had been effective as a war measure. It had simplified railroad operation at the ports by having separate tracks for each pool classification and cars could be unloaded continuously without "drilling" out the cars of each individual shipper. But for the priority orders to the public utilities during August, September and until October 15, they would have met inevitable disaster and the country would have faced a national calamity.

Mr. Lieb then gave the following figures obtaining under the conditions prevailing during the period 1916–1920:

	1st 6 Mos. 1916	1st 6 Mos. 1920	Increase, per cent
Kilowatt-hours generated	322,750,850	422,070,915	30.8
Coal consumed, tons	289,289	438,834	51.7
Cost of coal (in bunkers) used	$921,331	$3,195,984	247.0

The pounds of coal per kilowatt-hour generated rose from about 2 lb. in the first six months of 1916 to $2^1/_3$ lb. the first six months of 1920, reaching as high a figure as 2.5 lb. for the second half of 1919, a decrease in efficiency of 25 per cent.

In the meanwhile the price had risen from approximately $3.20 per ton in the first half of 1916 to $7.30 per ton average for the first half of 1920; or, as expressed in cost of coal per kw-hr. at the generating-station switchboard, from 0.29 cent per kw-hr. to 0.76 cent per kw-hr., with a present cost of coal in the bunker of approximately $8.80 per ton and a coal cost of 0.9 cent per kw-hr. generated.

The question of storage of coal, Mr. Lieb said, might be regarded from two viewpoints: first, the endeavor to stabilize the output of the mines, make production more regular and uniform, and provide more continuous employment to the labor at the mines; and second, to protect the user against irregular deliveries due to unfavorable weather conditions, interference and delays in transportation, congestion at port terminals and harbor and switching difficulties. The former would call for storage at the mines, the latter, at the point of consumption.

The amount of storage necessary would depend on the size of a mine and the scarcity of cars, and car shortage had undoubtedly been the most serious of the difficulties encountered during the past year or two. Roughly, the average output of the mines is not over 50 per cent of their capacity, and, considering this caused entirely by lack of cars, it would appear that as the car shortages are rather daily than weekly or monthly, a bin storage capacity of 40 cars or approximately 2000 tons would be ample to take care of a 1000-ton mine. Taking the mean between the cost of wooden and concrete construction, the fixed charges on a 2000-ton pocket and machinery would amount to 7.5 cents per ton, which would be quite lost in consideration of the added output of 80,000 tons per year, and the more constant employment of labor with its enhanced efficiency.

The problem of storage at the point of consumption presented greater difficulties. It had been the experience of public utilities over many years that even in normal times it was necessary to provide for a reserve supply of fuel in storage to last from 45 to 60 days, dependent upon the proximity of the utility to its base of supply, its location on rail or water routes, dependency on one or more alternate transportation routes, rail or harbor terminal facilities, labor, barging, etc. On the limited areas usually available near large power plants this required the massing in piles of considerable height, introducing the difficult problems of protection against spontaneous combustion and the necessity of moving the coal in case of trouble. These contingencies, however, had to be met and the expense faced in order to safeguard continuity of operation.

It had been proposed that in order to stimulate the accumulation and storage of coal during the summer months when its transportation can be more easily accomplished, a lower freight rate be established during the season of favorable transportation conditions and a higher rate for the remainder of the year.

In conclusion, Mr. Lieb said that it would be seen that the problem of an adequate and regular supply of fuel to the public utilities was an important factor in our national economy, and that such a measure of practicable supervision and regulation of the production and distribution of the fuel supply to the railroads, army and navy, public utilities and public institutions should be assured as would secure to the public the guarantee of continuity of operation of these essential factors of modern civilization in the paramount public interest.

J. H. McNally. Since it is the intention of the Fuel Section to obtain, through coöperation, an exchange of ideas on the subject of fuels it is my theory that this coöperation should begin with the coal operator and not at the power plant. In seeking to coöperate with the various engineers in the power-plant field, we have great difficulty in ascertaining the kind and quality of coal that they desire, the usual saying being any low-ash, low-sulphur steam coal. As you know, this grade of coal is being very rapidly acquired by the metallurgical industries, so that in a short time none will be available for steam purposes, and it is my belief that a general educational campaign along the lines of utilizing our lower-grade coals, where fusion temperature and not sulphur is the index of the quality, would be very much in order.

Horace C. Porter. There is a confusion of statement and possibly of ideas as to the economic practicability of expansion in the industry of converting coal into coke, gas, and by-products. It is often assumed that this expansion would necessarily mean the displacing of raw coal for boiler fuel. As a matter of fact, however, coke and gas cannot compete with raw coal as a boiler fuel, even with the credit from the by-product ammonia, unless it be in large superpower stations, which sell the highest-grade coke and part of the by-products at prices well in excess of their relative B.t.u. values.

The abandonment in some measure of raw coal as boiler fuel may result from increasing use of centrally developed electric power from super-stations. Gas-fired boilers also may sometime prove to have lower overall costs than coal-fired, but the great field for expansion of coal carbonization lies in the other 35 to 40 per cent of our coal consumption not applied to steam raising. Beehive coking can and should be practically all displaced by recovery coking. The coal used in metal-heating and other industrial heating furnaces is probably 10 to 15 per cent of our total consumption. Gas and coke, or semi-coke, in the domestic field can be largely extended with profit, if the regulatory commissions will generally permit a B.t.u. standard for gas low enough so that manufacturing methods of highest thermal efficiency and therefore lowest costs can be used.

But for boiler firing, a much larger field, the problem is more

order to pay for themselves, must have a practical value in application equal to 160 per cent of that of the coal, and this they do not have as boiler fuels in the present state of the art.

O. P. Hood. Mr. Myers points out many places where there is evident waste of coal and suggests that Government interest itself in the matter. Our machinery of government has developed through an effort to minimize these wastes of human imperfection, but comparatively little governmental machinery touches the waste of natural resources and the production of energy. In fact, it has been considered wisest to leave such matters as largely as possible to the interaction of individual effort. When, however, one realizes the national significance of serious waste, it is a natural thought to invoke the power of the state to police the situation. That the Government must help in the matter of energy conservation in order to protect its own life will sometime become evident to all the people and at that time many governmental agencies can be effectively employed to save coal. At the present time it is a question as to what extent the Government can interest itself effectively in this basic question. However, one perfectly safe method with which most everyone will agree is the use of educational methods which contain no element of compulsion.

It has been the opinion in the Bureau of Mines that perhaps the greatest need and the one on which attention should first be focused is that of providing machinery whereby the coal industry may be helped to maintain a reasonable standard of quality. The Bureau of Mines proposes a fuel-inspection system which contemplates as a salient feature advice to the public as to the quality of coal as shipped. The only force depended upon to produce results is a public statement of the facts, rather than the arbitrary police power needed in time of war. For this purpose the machinery for accurate sampling of full carload lots by an impartial organization is necessary. The Government now possesses facilities for analyses and publication.

It is proposed that each mining company set its own standard of quality, consistent with the particular vein, preparation, and market which the business affords, and that the government shall publish such standard and certify as to whether such standard is being maintained by the mining companies. Such work would not replace inspection by the mining companies. It would not certify as to the quality of each and every shipment, but it would inspect and sample at irregular intervals a sufficient number of cars of coal as shipped to indicate whether the declared standard of the mining company was being maintained.

It is believed that some measure of this kind, akin to our meat and wheat inspection system, fits the public temper at the present time and would be a real help in fuel conservation without going too far in governmental contact with business.

Walter N. Polakov. We have created public-service commissions and other governmental and official bodies to supervise the functioning of our public utilities. But so far as fuel consumption goes our gas works are using only about 1 per cent and our public-utility companies about 7 per cent of the coal, which is less than that annually destroyed by beehive coke ovens alone. Also the industrial steam trade consuming 33 per cent and the railroads, who are the greatest wasters, are allowed to continue to do so quite unmolested by public opinion.

During the war we created the Fuel Administration, but we were not consistent enough to carry out the good intentions to a true, logical conclusion by denying to the reckless and incompetent plants the privilege of wasting fuel. But even half-hearted measures to meet temporary expedients taught us a bitter lesson. We all have learned how easy it is for those who know to show how to prevent a goodly part of coal which we throw away and to secure which we keep thousands of men in mining and railroad industries doing utterly useless work. Patriotic motives being rapidly forgotten, the half-billion-dollar loss in fuel is cheerfully included in the cost of production of various commodities and now we have come to repent. Of course I do not mean to say that waste of coal by manufactur rs is alone responsible for high prices and dull

Referring now to the paper by Messrs. Gilbert and Pogue, its exceptional value is due, in my estimation, to the fact that the authors clearly conceived and successfully applied to the solution of their problem all three forms of modern engineering: (1) technological, (2) economic and (3) social. Every industrial, creative problem must necessarily be studied from all these aspects, for otherwise the "abstract" engineering of a technician may prove to be either economically unsound or socially worthless.

The relative importance of form values in practice is usually obscured if not altogether disregarded because of wide divergence in economic advantages depending upon managerial ability of users of energy. Charts as prepared by Rockwell are theoretically interesting but practically misleading. Under poor management of the best-fitting and theoretically advantageous form energy it does often appear as wasteful. The electrical form of heating is inferior to gas or steam, but when management cares little as to methods of operation, electricity gives ultimately higher economy. Likewise fuel oil used under boilers is wrong from a broader economic aspect, but in practice coal is used so recklessly under either incompetent or disinterested management that fuel oil gains in popularity. In other words, the problem that must be solved in parallel with that pointed out by the authors is one of the immediate elimination of such wastes in power generation, distribution and utilization as now obscure the true significance of "form value" and stand in the way of both "integration of industry" and establishment of an "unbiased court of appeal," for otherwise its consideration will be distorted by wide variations in the degree of managerial efficiency in employing different sources of power.

G. H. Sharpe. Before the war, coal organizations, confining myself particularly to the Eastern bituminous field, started their selling organizations about April 1st, the recognized beginning of the coal year, and vigorously solicited contracts for the delivery of coal over the twelve future months. Purchasing agents for industries and railroads, however, studiously refused to enter into contracts providing for a regular flow of coal during the months of April, May, June and July, and in many cases, August, thus crowding the major portion of their demands into the months of September to March, inclusive, with all the attendant handicaps of difficulties in transportation and lowered output per miner during the winter season.

The coal operator found no reasonable market for his output during these dull months and knowing the expenses of a shutdown, turned to the middleman or broker, and he in turn drove a hard bargain for the delivery of a fixed tonnage per month over the year.

This practice has built up a brokerage class who are much wiser than the purchasing class in coal distribution and much stronger financially than the larger percentage of operators, and they have simply seized the opportunity that has been afforded them during the past year.

As engineers it is our duty to aid in the education of the coal consumers. They must buy and store coal every month in the year and they must buy and store a greater tonnage from April to September, inclusive, than during the remainder of the coal year. The larger public utilities are, as a rule, consistent in their coal purchases, but the greater number of small public-utility plants are dilatory, so that in the end all must suffer equally for the Fabian tactics of the majority. Some of the public utilities, however, are able to pass the additional cost along to the public, who, after all, are in a great measure responsible for the conditions.

Charles C. Phelps. Many engineers have no opportunity for saving fuel except in the particular plants with which they are connected. Hence it is of interest to have data for comparing results obtained in different plants. An article by David Brownlie published recently in the *Chemical Trade Journal and Chemical Engineer* gives interesting figures representative of British boiler plants. In an investigation of 250 miscellaneous plants and of 60 chemical plants, tests representative of everyday operation and

Power Test Codes

A.S.M.E. Committee Appointed to Formulate a Test Code for Reciprocating Steam Engines, Submits the Preliminary Draft Given Below

IN 1918 the Power Test Committee of the A.S.M.E. was reorganized to devise and enlarge the Power Test Codes of the Society, published in 1915. The Committee is a large one, under the chairmanship of Fred R. Low, and under its direction are 19 individual committees of specialists who are drafting codes for the different classes of apparatus comprised in power-plant equipment. Below is reproduced the second of these codes to be completed, namely, the Test Code on Reciprocating Steam Engines. This Code was prepared by a committee consisting of William C. Brown, Chairman, Alexander G. Christie, Secretary, George H. Barrus, Harte Cooke, Herman Diederichs, J. F. Max Patitz, and Fred H. Vose.

This Committee will, of course, welcome suggestions for corrections or additions. These should be mailed before February 1 to the Chairman, care of The American Society of Mechanical Engineers.

Test Code on Reciprocating Steam Engines

Introduction

1 The code for steam-engine tests applies to tests for determining the performance of the engine alone (including reheaters and jackets, if any), apart from that of the independently driven auxiliaries which are necessary for its operation, and apart from that of feedwater heaters or other apparatus for reclaiming heat. For tests of an engine and independently driven auxiliaries combined with means for reclaiming heat (for example, a multiple-expansion engine from the receiver of which steam is withdrawn for heating feedwater or other purposes), the rules given in the Code for Complete Steam Power Plants should be followed.

Object

2 In accordance with the "General Instructions" the object of the test should be determined and recorded. If the object relates to the fulfillment of a contract-guarantee, an agreement should be made before the test between the interested parties concerning all matters about which dispute may arise, as noted in Par. 3 of the "General Instructions," and the points agreed upon should be stated in the Report of the Test.

Measurements

3 The measurements that must be made in a performance test of a reciprocating engine will consist of some or all of the following quantities:

(a) The cylinder diameters and stroke
(b) The volumetric clearance in per cent of the piston displacement
(c) The diameters of piston rods and tail rods
(d) The indicated horsepower
(e) The brake horsepower or shaft horsepower output
(f) The kilowatt output if engine is connected to a generator
(g) The speed in revolutions per minute
(h) The pressure in the steam pipe before the throttle
(i) The barometric pressure
(j) The percentage of moisture or number of degrees of superheat in the steam just before the throttle
(k) The back pressure in the exhaust pipe near the engine cylinder
(l) The receiver pressure
(m) The temperature of the exhaust steam leaving all cylinders
(n) The temperature of the drips if any, from jackets, reheaters and receivers.
(o) The temperature of steam leaving receivers, cylinder jackets, reheaters and similar parts
(p) The weight of return drips from jackets, reheaters and receivers
(q) The weight of the condensed steam in pounds or the weight of the water fed to boilers, less drips and leakage if the test is based on feedwater fed to boilers, less drips and leakage if the test is based on feedwater measurement
(r) The temperature of the condensed steam
(s) Engine-room temperature and outside air temperature
(t) The variation in steam pressure in the steam chest.

Instruments and Apparatus

4 The instruments and apparatus required for a performance test of a reciprocating steam engine are:

(a) Tanks and platform scales for weighing water (or water meters calibrated in place)
(b) Graduated scales attached to the water glasses of the boilers if the feedwater is measured
(c) Pressure gages, vacuum gages or mercury columns and thermometers
(d) Steam calorimeters
(e) Barometer
(f) Steam-engine indicators
(g) Planimeter
(h) Tachometer, revolution counter or other speed-measuring apparatus
(i) Friction brake or dynamometer, if available
(j) Appropriate electrical instruments if engine is connected to an electric generator.

Directions regarding the application, use, and calibration of these instruments and apparatus and statements as to their accuracy are given in Pars. Nos. ——— of the Code on Instruments and Apparatus.

Preparations

5 Before proceeding with an engine test Pars. 4 to 8 of the "General Instructions" should be carefully studied. The dimensions and the physical condition not only of the engine but of all associated parts of the plant essential to the object of the tests, should be determined and carefully recorded. The following paragraphs suggest methods by which this information may be secured if required.

Dimensions

5a The dimensions of engine cylinders should be taken when they are cold. If extreme accuracy is desired as in scientific investigations, corrections should be applied to the cold dimensions to conform to the mean working temperature. If the cylinders are much worn, the average diameter should be found. The clearance of the cylinders may be determined approximately from working drawings of the engine. For accurate work, when practicable, the clearance should be determined by the water-measurement method. To carry out this method, set the engine exactly on the center, with the piston at the end of the cylinder where the clearance is to be determined. From a quantity of water previously weighed pour enough into the clearance space by means of a funnel through some available opening, such as may be obtained by removing a steam valve in a horizontal four-valve cylinder, or through indicator cocks, until the clearance space is completely filled. By weighing the water remaining the amount necessary to fill the clearance space can be obtained, and by making the proper allowance for temperature the clearance volume may be calculated. The percentage of clearance is found by dividing the clearance volume thus found in cubic inches by the volume displaced by the piston in one stroke, also in cubic inches. Care should be taken to see whether the clearance space is so arranged that no air is retained when it is filled with water. If such pockets cannot be properly vented, this method will not give accurate results. When full, the gradual lowering of the water will show leakage by the valves or piston. Allow leakage to go on for a certain time, then from a quantity of water previously weighed pour enough into the clearance space to fill it up again, note the time it takes to do this and weigh the water remaining after filling up the clearance space. Then the weight of water from which clearance space is to be calculated (W_1) can be determined as follows:

$$W_1 = W - \frac{wT}{t - t_1}$$

Where W = weight of water filled into clearance space.
T = time to fill clearance space
t = time allowed for leakage
w = weight of water for filling space up again
t_1 = time required to fill clearance space again.

This method will give the proper correction to be subtracted if the leakage is not very great. If the leakage is too great, and the object of the test will allow it, the valves and piston rings must be put in proper condition.

The area of interior steam surfaces is all of that part of the interior of the steam cylinder, the piston head and the parts back to the valves that are exposed to the steam at the time that the exhaust valve is opened. If desired, the clearance surfaces can be calculated by subtracting from this interior steam surface the area of the circumferential walls of the cylinder from the location of the piston at the dead-end center to the location of the piston when the exhaust valve first opens.

the circulating water, steam is allowed to pass into condenser until the condensate flows out of the opening in the bottom. Then the steam is turned off the engine and careful note is taken whether or not the flow of water stops, thereby testing the tightness of the condenser. (See Par. 6a for method of testing condensers for tightness when measuring condensate.) The engine should then be blocked just beyond the head-end center, with the valves in mid-position with full steam lap, the throttle opened and the leakage weighed for each minute for fifteen minutes or a half-hour, thereby determining the rate. This operation should be repeated with the engine just beyond the crank-end center. Each of these tests gives the leakage by one steam valve, one exhaust valve and the piston. If the leakage is only nominal no further leakage tests need be made, but if the leakage is excessive its source should be determined. In any case it cannot be assumed that such tests give an exact measurement of the leakage under operating conditions. They merely indicate the degree of leakage.

5c In testing for the degree of leakage in the high-pressure cylinder of a compound engine the exhaust valves of the low-pressure cylinder, or the relief valves if they are connected to the condenser, should be opened to allow the leakage to pass. The low-pressure cylinder may be tested like that of a single-cylinder engine by admitting steam to it through the receiver and by-pass valve. Care should be taken when thus testing a compound engine that the pressure differences applied in both cylinders are approximately the same as the working pressure differences.

5d If the engine has no surface condenser, a small one can be fitted up, or the leakage condensed by letting it flow into a barrel of cold water. If the engine is reasonably tight it may be assumed that the leakage should not exceed one-tenth of a pound per rated horsepower per hour, or one per cent of full-load steam consumption, so that the capacity of the small condenser or barrel of cold water need not exceed this amount.

5e A method of testing for the degree of leakage of valves and pistons by observation in a four-valve engine, or an engine in which the admission valves can be worked by hand independently of the exhaust valves, is as follows: The engine is turned until the piston is about mid-stroke. The two steam valves are closed, the two indicator cocks are opened, and the full pressure of steam is admitted into the chest by opening the throttle valve. The starting bar is then moved first one way and then the other, closing first one and then the other exhaust valve, and the degree of leakage by the steam valves can be roughly judged by the force of the steam coming out of the indicator cocks. To test the exhaust valves and piston, the flywheel is blocked so that the piston will be at a short distance from the end of the stroke, and the steam is turned on. The leakage then escapes to the exhaust pipe, and can be observed at the open atmosphere outlet. If the outlet is not visible and there is a valve in the exhaust pipe, this can be shut and the indicator cock on the opposite end of the cylinder opened, thereby diverting the steam which leaks and causing it to appear at the indicator cock. In a condensing engine where no atmospheric exhaust is provided, and where there is no opening that can be made in the exhaust pipe between the engine and the condenser, some idea can be obtained in regard to the amount of leakage by observing how rapidly the condenser is heated. It is well to make these tests with the piston in different positions, so as to cover the whole range of the length of the stroke.

5f Another method of testing for the degree of leakage is called the "time method." Instead of observing the steam that actually blows past the valves or piston to be tested, they are subjected to full steam pressure, and when the parts are thoroughly heated, the throttle valve is shut and the length of time which is required for the pressure to disappear is observed. In testing the piston and exhaust valves, the flywheel is blocked as before, and, preferably, an indicator is attached, and lines drawn on a blank card at intervals of, say, one-quarter of a minute after the valve is shut, thereby making a record of the fall of the pressure. In a tight engine the fall of the pressure is slow, whereas in a leaky engine it is sometimes very rapid. The relative condition of the engine under test as compared with a tight engine must be judged by the observer, who must, of course, have had experience in tests of this kind on engines in various conditions. The leakage of a piston may be determined by removing the cylinder head, after first blocking the engine, and observing what blows through the open end with the pressure of steam behind it. The advantage of the time-method is that it saves the labor and time required in removing the cylinder head and replacing it, which, in the case of large engines, is considerable.

5g Leakage tests of single-valve engines cannot be made as satisfactorily as those of the four-valve type. The best that can be done as regards the valve is to place it at or near the center of its travel, covering both ports, and then make the test under full pressure. The valve and piston can be tested as a whole by blocking the flywheel and opening the throttle valve in the same way as in the other engines.

5h In testing compound engines for the degree of leakage the work is somewhat simplified, as compared with a simple engine. For example, leakage of the high-pressure cylinder can be revealed by opening the indicator cock on the proper end of the low-pressure cylinder, the steam valve of that cylinder being open. The test of leakage of the low-pressure exhaust valve and piston when the time method is used may be based on the indication of the receiver gage, instead of using an indicator. In that case the fall of the pressure due to leakage is read directly from the gage.

5i In four-valve engines the degree of leakage of the piston with the there is no chance for leakage, this is sufficient. For example, where a straight-way valve is used for cutting off a connecting pipe, and this valve has double seats with a hole in the bottom between them, this being provided with a plug or pet cock, assurance of the tightness of the valve when closed can be had by removing the plug or opening the cock. Likewise, if there is an open drip pipe attached to an unused or empty section of pipe beyond the valve, the fact that no water escapes here is sufficient evidence of the tightness of the valve. The main thing is to have positive evidence in regard to the tightness of the connections, such as may be obtained by the means suggested above. But where no positive evidence can be obtained, or where the leakage that occurs cannot be measured, it is of the utmost importance that the connections should be broken and blanked off. Leakage of relief valves which are not tight, drips from traps, separators, etc., and leakage of tubes in the feedwater heater must all be guarded against or measured and allowed for. It is well as an additional precaution to test the tightness of the feedwater pipes and apparatus concerned in the measurement of the water by shutting the feed valves at the boilers, making sure that they are tight, and turning steam on to the feed pump. If there is no leak the pump can run only as fast as is permitted by its own slippage. Leakage will be revealed by disappearance of water from the supply tank. A gage should be placed on the pump discharge to guard against undue or dangerous pressure.

5k To determine the leakage of steam and water from boiler, steam pipes, etc., up to engine throttle valve, the water-glass method may be satisfactorily employed. This consists of shutting off all the feed valves (which must be known to be tight), including the main feed valve, thereby stopping absolutely the entrance or exit of water through the feed pipes to or from the boiler; then maintaining the steam pressure in boiler and steam lines (by means of a very slow fire) up to a fixed point, which is approximately that of the working pressure, and observing the rate at which the water falls in the gage glasses. It is well, in this test, as in other work of this character, to make observations every ten minutes, and to continue them for such length of time that the differences between successive readings become constant. In many cases the conditions will have become constant at the expiration of fifteen minutes from the time of shutting the valves. In boilers with much brickwork, especially if run at a high rate, it will be several hours before pressure conditions become constant and safety valves stop popping. Thereafter the fall of the water level due to leakage of steam and water becomes approximately constant. It is usually sufficient, after this time, to continue the test for two hours, thereby obtaining a number of half-hourly periods. When this test is finished, the quantity of leakage is ascertained by calculating the volume of water which has disappeared, using the area at the water level and the depth shown on the glass, and multiplying by the weight of one cubic foot of water at the temperature observed. The water columns should not be blown down during the time a water-glass test is going on, nor for a period of at least one hour before it begins. If there is opportunity for condensation to occur and collect in the steam pipe during the leakage test, the quantity should be determined as closely as possible and properly allowed for.

6 *Steam Consumption.* The steam consumption of an engine equipped with a surface condenser should be determined by measuring the condensate from the condenser, assurance being obtained that all the steam entering the cylinders passes into the condenser. If the condenser leaks, the defects causing the leaks should be remedied or suitable corrections should be made. The water of condensation from jackets and heaters, if not included in the condensate, should be weighed separately and added thereto. If a surface condenser is not available, the steam consumption should be determined by feedwater tests, which require the measurement of the various supplies of water fed to the boiler, of the water wasted by separators and drips on the main steam line, of the steam used for other purposes than the main engine cylinders, and of water and steam which escape by leakage from the boiler and piping. All of these last quantities must be determined and be deducted from the total measured feedwater supplied to the boiler. The heat consumption is determined from the steam consumption as pointed out in Par. 12.

6a In making an engine test where the steam consumption is determined from the amount of water discharged from a surface condenser, leakage of the piston rods and valve rods should be guarded against; for if this is excessive, the test is of little use, as the leakage consists partly of steam that has already done work in the cylinder and partly of water condensed from the steam in contact with the cylinder. Leakage of the condenser itself may be determined by operating the condenser under vacuum when all steam from the engine is shut off, and observing the rate at which the water, if any, is discharged by the condensate pump. When salt water is used for circulating water, leakage may be determined by testing the condensate with silver nitrate or by some other suitable method such as the conductivity bridge or the Dionic tester. If a few drops of solution of silver nitrate added to a sample of condensate produce a white precipitate, the presence of salt water is indicated.

6b When no other method is available, the steam consumption may be determined approximately by the use of a steam meter calibrated under the conditions of use.

6c The steam consumed by independently driven auxiliaries which are required for the operation of the engines should not be included in the total steam from which the steam consumption is calculated. These should be supplied from a separate boiler, if possible, if the steam consumption is determined by the measurement of feedwater.

6d The steam consumption of auxiliaries may be determined approximately by the water-glass test, as described in Par. 5k.

Operating Conditions

7 The operating conditions conforming to the object in view should prevail throughout the trial, as pointed out in Par. 19, of the "General Instructions."

Starting and Stopping

8 The engine and appurtenances should first be thoroughly heated and run under the prescribed conditions until uniformity is secured. If the period to be covered by the test includes the time employed in warming up a cold engine, as in the practice of many industrial plants, the preliminary heating should be omitted, and the conditions should all conform to the usual operations.

8a When a surface condenser is used, the test should start by commencing to weigh or measure the condensate and any other quantities of steam consumption involved, at the same time beginning the regular observations and other necessary test work. At the end of the allotted time the test is stopped by discontinuing the measurements and observations. When feedwater measurements are employed, the test should be started by carefully observing the steam pressure and water level in the boiler, and the level in the feed tank, if measuring tanks are used, at the same time beginning the water measurements and taking up the regular work of the test. At the end of the prescribed time, the water levels and steam pressure should be brought as near as practicable to the same points as at the start, and the observations discontinued. If there are differences in the water levels or pressure, proper corrections must be applied to the water measurements.

8b When feedwater measurements are employed care should be taken in cases where the activity of combustion affects the height of water, that the same conditions of fire and draft are secured at the end as at the beginning. Care should also be observed to note the average height of water in the glass when the water line fluctuates.

Duration

9 When surface-condenser measurement is employed and the load is substantially constant, the test should be continued for such time as may be necessary to obtain a number (not less than three) of successive half-hourly records during which the results are reasonably uniform. When the steam consumption is determined by measuring the feedwater supplied to the boiler, the run should be as long as the operating conditions permit. For accurate results the duration of such a test should be at least five hours.

9a When the conditions determined upon are such that the load varies widely at different times, the duration should be such as to cover at least the entire period of variation.

Records

10 The general data should be recorded as pointed out in Pars. 20 to 30 of the "General Instructions." Instruments should be read and indicator cards taken from each end of each cylinder at least quarter-hourly when the conditions are uniform and oftener when there is much variation. If there are wide fluctuations in readings they should be shown by recording instruments. Each indicator card should be marked with the number, date, time, scale of spring and end of cylinder, and on one card of each set the readings of the steam gages should be recorded. The log should contain the record of the readings of steam and vacuum gages, thermometers, calorimeters, speed indicator, load-measuring devices, and all other instruments, and these readings should be obtained at practically the same time the indicator cards are taken. The areas, lengths, mean effective pressures, and cut-offs shown by the indicator cards, should also be entered in the log. If complete test data are desired, representative steam-pipe diagrams should be taken with an indicator applied near the throttle-valve gage and operated by connection to the reducing motion of the cylinder indicators.

10b A set of specimen indicator diagrams should be carefully selected from the whole number taken, and these should be embodied in the record. The specimen cards selected should be such as to show the average conditions of pressure and cut-off. If steam-pipe diagrams are obtained, specimens of these should also be placed in the record.

Calculation of Results

11 *Steam Consumption.* Whether the engine is supplied with wet, dry and saturated, or superheated steam, the actual steam consumption is stated in the report of the test. When the engine is supplied with wet steam, the quantity of dry and saturated steam comprised in the wet steam is found by deducting from the total weight of steam as measured the moisture as shown by a calorimeter near the throttle. Superheated steam requires no correction. The "equivalent steam" consumed corresponding to any desired or specified set of conditions as to moisture, superheat, pressure, and vacuum which differ from the conditions of the test —such, for example, as those required by a contract guarantee or acceptance test—should be determined in the manner previously agreed upon by the interested parties in accordance with Par. 3 of the "General Instructions." (See Code on Definitions and Values, Par. 93.)

11a In view of the fact that "dry saturated steam" is practically unobtainable commercially and that the presence of moisture is detrimental to the economy of the engine to a greater degree than the amount present in the steam would indicate, arbitrary corrections (referred to in Par. 11 above) for correcting the actual steam consumption for quality are to be used in arriving at a value of "Equivalent Steam."

12 *Heat Consumption.* The number of heat units consumed by an engine per hour is found by multiplying the consumption, as measured in pounds of steam per hour, by the difference between the total heat in one pound of steam at the average pressure and of the average quality found in the steam pipe near the throttle and the heat in one pound of water at the temperature of saturated steam at the average pressure existing in the exhaust pipe near the cylinder.

13 *Indicated Horsepower.* The indicated horsepower for each end of the cylinder is found by using the formula

$$\text{I.hp.} = \frac{P\,L\,A\,N}{33{,}000}$$

where P represents the mean effective pressure in pounds per square inch, L the length of the stroke in feet, A the area in square inches of the piston less the area of the piston rod, if any, and N the number of revolutions per minute. The total horsepower of the cylinder is the sum of the horsepower developed in the two ends.

13a The mean effective pressure should be found by dividing the area of the diagram in square inches as determined with a correct planimeter, by the length of the diagram in inches, and multiplying the quotient by the average corrected scale of the indicator spring. If a planimeter is not available, the approximate mean effective pressure may be determined by finding the average height of the diagram in inches as obtained by averaging a suitable number of ordinates, at least ten, measured between the lines of the forward and return strokes, and then multiplying this average by the scale of the spring.

14 *Brake Horsepower.* The brake horsepower is found by multiplying the net pressure or force W in pounds on the brake arm —that is, the gross pressure minus the weight when the brake is entirely free from the pulley—by the circumference of the circle whose radius is the horizontal distance L in feet between the center of the shaft and the bearing point at the end of the brake arm, and by N the number of revolutions of the brake shaft per minute, and dividing the final product by 33,000.

$$\text{B.hp.} = \frac{2\,\pi\,LWN}{33{,}000}$$

See Code on Instruments and Apparatus for descriptions and methods of applying brakes.

15 *Electrical Horsepower.* The electrical horsepower of a generator is found by dividing the output at the terminals expressed in kilowatts by the constant 0.7457. In the case of an alternating-current generator the quantity of output determined, whether expressed in electrical horsepower or kilowatts, should be the net output. When the power for excitation or ventilation is taken directly from the engine shaft, the net output is that indicated at the a.c. generator terminals. When this power is taken from the a.c. generator through a motor or from some outside source, the net output is found by deducting the current furnished as excitation from that indicated at the terminals.

16 *Thermal Efficiency.* The proportion of the total heat consumption which is converted into work is called the "thermal

efficiency in per cent. The formula is

$$\text{Thermal Efficiency} = \frac{2547}{w\ (H_1 - q_2)}$$

where w = pounds of steam as supplied per i.hp-hr.

H_1 = total heat above 32 deg. per pound of steam at the initial conditions prevailing before throttle valve.

q_2 = heat of liquid above 32 deg. in one pound of water at the temperature of saturated steam at exhaust pressure.

17 *Engine Efficiency.* The engine efficiency is the ratio obtained by dividing the heat equivalent of the actual work done by the heat available for an ideal engine. The accepted standard for the ideal steam engine is the Rankine cycle (Code on Definitions and Values, Par. 89). The engine efficiency is obtained by the following equation:

$$\text{Engine Efficiency (referred to i.hp.)} = \frac{2547}{w\ (H_1 - H_2)}$$

where w = pounds of steam per i.hp-hr.

H_1 = total heat above 32 deg. per pound of steam at the initial conditions prevailing before the throttle valve

H_2 = total heat above 32 deg. per pound of steam after adiabatic expansion from initial conditions to the final pressure.

H_1 and H_2 can be found from any Total Heat-Entropy diagram. $(H_1 - H_2)$ is the heat available for work.

18 *Nominal Cut-Off.* The nominal cut-off can be found in the following manner from an indicator card: Through the point of maximum pressure during admission a line is drawn parallel to the atmosphere line. Then through a point near the top of the expansion line where the cut-off is complete, a hyperbolic curve is drawn. The intersection of these two lines is the point of nominal cut-off, and the proportion of cut-off is found by dividing the length measured on the diagram up to this point by the total length, as shown in Fig. 1.

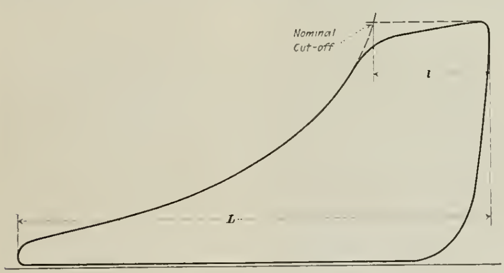

Fig. 1

Note.—The method of calculating the steam accounted for by the indicator card has been omitted for the following reasons:

(*a*) It is not essential to a performance test of an engine;

(*b*) As this method does not even approximate the actual steam consumption of an engine, it is liable to be misleading unless thoroughly understood.

19 *Throttle Pressure.* The throttle pressure, or the average pressure in the steam pipe just before the throttle, is that shown by a corrected steam gage attached at the desired point, the fluctuations of which are reduced so far as may be by choking the gage cock. When extreme accuracy is desired or when the fluctuations are large the average pressure may be found by working up the steam-pipe diagram taken at or near the same point and finding the mean pressure for the entire stroke, during the periods of admission. The superheat or quality of the steam supplied should be measured in the steam supply pipe before the throttle valve.

19a In the case of guarantee tests of capacity, if so agreed upon, the throttle pressure may be taken as the minimum pressure shown on an indicator diagram taken from the steam pipe near the throttle.

the form (Table 1) given herewith, adding lines for data not provided for, or omitting those not required, as may conform to the object in view. If the principal data and results pertaining to steam consumption only are desired, the subjoined abbreviated table (Table 2) may be used. Unless otherwise indicated, the items should be the averages of all observations.

See Note 1 of Table 1 for references to engines driving electric generators and other machinery.

TABLE 1 DATA AND RESULTS OF RECIPROCATING STEAM-ENGINE TEST

(*A.S.M.E. Code of 1920; Long Test*)

General Information

(1) Date of test ....

(14) Steam actually consumed per i.hp-hr...lb.
(15) Dry and saturated steam or superheated steam consumed per i.hp-hr...lb.
(16) Equivalent steam consumed per i.hp-hr. conforming to conditions agreed upon...lb.
(17) Engine efficiency (referred to Rankine cycle based on i.hp.) ...per cent

New Process of Steel Manufacture

A company has been incorporated at Etamps, 50 miles south of Paris, for the commercial exploitation of a patented process for manufacturing steel directly from the ore using an inclined rotating furnace similar to that employed in the manufacture of cement.

In this process—the Basset—the ore is charged at the upper end and works its way toward the lower end as the furnace slowly revolves—at the rate of one revolution in three minutes. Pulverized coal is used for fuel. The air which supports the combustion is previously heated about 1000 deg. cent. in a regenerator similar to that connected with an open-hearth furnace. The temperature of the gases as they leave the furnace is said to be 300 deg. cent. and by the nature of the process these gases contain 44 per cent carbon monoxide. This gas of course may be used for heating purposes. The slag is tapped off the top of the metal which is poured into the ingot molds.

It is claimed that three qualities of metal have been produced, including pig iron of a grade between gray and white, hard steel, and malleable iron. These results are obtained by varying the ore charge and the temperature of the process.

It is stated that since the first experiments at the Lavocat Usine at Dennemont, 2000 tons of iron have been produced by this process at Longwy. It also is stated that the Hauts Fourneaux de Caen has produced 500 tons. In the latter district it is now planned to erect a battery of furnaces with a capacity of 2000 tons per 24 hr.

American engineers, says *The Iron Trade Review* of November 11, 1920, will be struck with the similarity between this process and the Jones step process which was the subject of extensive trials at Marquette, Mich., over a decade ago. In view of the utter commercial failure of the Jones process, the progress of the French experiments will be watched with interest.

Notable Session on Transportation—Professional Sessions Interested Large Numbers of Membership—Brashear Memorial Meeting—Record Attendance

THE Forty-first Annual Meeting of The American Society of Mechanical Engineers had the distinction of being the richest in professional program of any meeting held by the Society. To this the newly formed Professional Sections contributed greatly. Their coöperation with the Committee on Meetings and Program in the carrying out of their several sessions prophesies a great future for the professional and technical activities of the Society. In fact, the organization of Professional Sections and the consequent quickening of the technical life of the Society is a step that well accompanies the formation of The Federated American Engineering Societies with its avowed purpose of dedicating the organization to service. To be of service the technical society must be intensively organized technically, and the Professional Sections fill this requirement in The American Society of Mechanical Engineers.

In the arrangement of general Professional Sessions this year no more than three papers were assigned to any session. This arrangement coupled with the adoption of limiting times for the presentation and discussion of these papers, insured more completely the carrying on of the meeting according to schedule and still permitted adequate time for the discussion of each paper. This arrangement, however, is subject to change and members are requested to send in to the Secretary any comments or criticisms of the new rules or the new arrangement of sessions.

The meeting formally opened on Tuesday, December 7, and contrary to the usual procedure, three sessions were held Tuesday afternoon. On Monday, however, the Local Sections' delegates gathered for their annual conference, which proved of great value as a meeting place for the discussion of Local Sections' problems and for the advancement of new ideas in Society policy. A more complete account of the Local Sections' Conference will be given in Part Two of the February issue.

The social functions consisted of the Presidential Reception on Tuesday evening, and the Ladies' Reception, Tea and Dance on Thursday afternoon. Thursday evening being left open for other than Society activities, a number of technical schools availed themselves of the opportunity for Reunion Meetings. The most notable of these was the meeting of the New York Alumni of Worcester Polytechnic Institute in honor of Governor-Elect Lake of Connecticut.

Wednesday evening was devoted to a memorial meeting in honor of the late Dr. John A. Brashear, Past-President of the Society. Mr. Worcester R. Warner, after a few words bearing on his intimate connection with Doctor Brashear, introduced the orator of the evening, Dr. Henry S. Pritchett, President of the Carnegie Foundation for the Advancement of Teaching. An abstract of Dr. Pritchett's address, entitled John Alfred Brashear, Humanitarian and Man of Science, is printed on page 39 of this issue.

Only one formal excursion was organized, the studio of the Metro Picture Corporation being visited. Small groups of members, however, were conducted to points of interest throughout New York City.

Registration totaled 2171, of whom 1368 were members and 803 guests—from twenty-nine states, Canada and France. This number exceeded last year's attendance, which was the largest previously recorded.

EDWIN S. CARMAN PRESIDENT, 1921
THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

Presidential Address and Reception

The meeting was formally opened on Tuesday evening with President Miller's address on The Engineer's Service to Society, which appears as the first article in this issue. Following the presidential address, honorary memberships were conferred upon the following men:

Captain Robert Woolston Hunt, of Chicago, Ill., Past-President of the Society and John Fritz Medallist, for his life-long and eminent achievements in the field of engineering, and particularly in connection with the steel industry;

Rear-Admiral Robert Stanislaus Griffin, of Washington, D. C., for his signal contributions to the engineering work of the naval forces of the United States during the World War;

Dr. Samuel Matthews Vauclain, of Philadelphia, Pa., Past-Vice-President of the Society, for his many important contributions to the mechanical engineering of the steam locomotive;

Honorable Sir Charles Algernon Parsons, of London, England, for his valuable contributions to the development and construction of the steam turbine which has now become an essential prime mover;

Lord William Weir, of Glasgow, Scotland, for his energy and genius in the organization of war work in the British Isles, and particularly as Director-General of Aircraft Production in the Ministry of Munitions; and

Grande Ufficiale Ingegnere Pio Perrone, of Genoa, Italy, for the unselfish devotion of his engineering and manufacturing skill to the cause of his country in the World War.

The first three recipients were present; official documents of honorary membership will be conveyed to the others through the American ambassadors in their respective countries.

The report of the tellers of election was presented by Dr. H. G. Tyler, who announced the election of officers for the ensuing year as follows: *President*, Edwin S. Carman, Cleveland, Ohio; *Vice-Presidents*, Leon P. Alford, Montclair, N. J., J. L. Harrington, Kansas City, Mo., and Robert B. Wolf, New York, N. Y.; *Managers*, Henry M. Norris, Cincinnati, Ohio, Louis C. Nordmeyer, St. Louis, Mo., and C. C. Thomas, Los Angeles, Cal.

President-Elect Edwin S. Carman was escorted to the platform by James Hartness, Governor-Elect of Vermont and Past-President of the Society, and Ira N. Hollis, Past-President of the Society. President Miller was welcomed to the past-presidency and back to

the membership of the Society by Governor Hartness and the new president was welcomed by Major Miller, who spoke of the services rendered by Mr. Carman as president of the Cleveland Engineering Society and as Chairman of the Local Sections Committee.

In acknowledging his election, Mr. Carman spoke briefly of the manner in which engineers should deal with professional matters, pointing out and emphasizing the fact that engineers, more than any other body of men, cannot attain satisfactory results without getting at the truth of every problem. The same accuracy which he must observe in designing a machine, Mr. Carman said, should be applied to every problem which the engineer undertakes.

Following these ceremonies the Presidential Reception was held and the remainder of the evening was devoted to dancing.

Business Meeting

President Fred J. Miller opened the Business Meeting on Wednesday morning with a few remarks on the growth of the Society, its participation in matters affecting the public welfare, especially its support of The Federated American Engineering Societies, and restrictions necessitated by increased costs. Reports of the various Standing and Special Committees of the Society were then presented by title by Secretary Rice. An abstract of these reports will be found in Section Two of this issue of Mechanical Engineering. The importance of the work of these committees was brought out by Secretary Rice.

The first report to be discussed was that of the Code of Ethics Committee. Prof. A. G. Christie, chairman of this committee, read the report and moved its adoption. The discussion which followed centered around the phraseology of the code, its purpose, and whether it should be the product of one man, a committee, or such an organization as The Federated American Engineering Societies. It was felt by many that the wording and style of the code should be changed so that it would be free from any possible criticism as to its English. A code so important, it was pointed out, should be couched in the purest possible language. There seemed to be considerable discussion, also, as to whether or not the purpose of the code was clearly understood. Several expressed the opinion that the code was not necessary as a guide for engineers, but should be a declaration of principles or a guide to the public as to what might be expected from the engineers in this and other societies. It was further suggested that the code should be an Engineers' Code, applicable to all engineers, rather than to mechanical engineers alone. It would thus become a creed for all engineers, a statement of their ideals, a standard for them in their work and at the same time a pledge to the public.

It was thought by some that a better code could be formed by one person, and the names of Felix Adler, an expert on the subject of ethics, Herbert Hoover and General Wood, for their knowledge of engineering, and President Wilson, for his mastery of the English language, were suggested as men to whom the code might be submitted for revision. Others felt that if the code were to apply to all engineers it might best be framed by the newly organized Federated American Engineering Societies, but it was argued that it might be some time before this body would be ready to consider codes and that in the meantime, both as a matter of courtesy to the committee which had drafted the code and as a means of keeping the work alive, the code should be referred back to the committee.

The motion which was finally carried was that the report be referred back to the committee for such action as they might deem wise, either for the modification of the code itself, for conference with other societies, or for the purpose of submitting the recommendations of the committee to The Federated American Engineering Societies. Professor Christie closed the discussion with the hope that further criticisms of the code would be sent to the committee.

Secretary Rice stated that the reports read by title should be discussed by correspondence. Among these he named the reports of the special committee on Standard Tonnage Basis for Refrigeration, Fluid Meters, and Bearing Metals; the special committee on Industrial Engineering; committee on Power Test Codes (General Instructions); special committee on Weights and Measures; special committee on Feedwater Heater Standardization; committee on Education and Training; and the committee on Awards and Prizes.

Professor H. S. Philbrick, secretary of the Sections Conference, read the report of that Conference, at which it was voted that junior members shall not be given the voting privilege in Society affairs, and the following names for the 1921 Nominating Committee were presented: Elmer Smith, Boston, Mass.; G. K. Parsons, New York; W. W. Varney, Baltimore, Md.; B. S. Hughes, Buffalo, N. Y.; W. M. White, Milwaukee, Wis.; F. E. Bausch, St. Louis, Mo.; and E. O. Eastwood, Seattle, Wash. The report was adopted.

F. E. Matthews, president of the American Society of Refrigerating Engineers, read the report on the Standard Tonnage Basis for Refrigeration. This report has been adopted by the joint committee of the Mechanical Engineers and Refrigerating Engineers, and by the American Society of Refrigerating Engineers itself. The report was referred back to the committee, to be presented at the next Council Meeting and brought up again at the Spring Meeting of the Society.

The meeting closed with the award of the Student Prize, details of which will be found elsewhere in this issue.

The meeting was adjourned until Friday afternoon for the presentation of two amendments to the Constitution, the report of the delegates to the American Engineering Council, and a statement on Appraisal and Valuation by Mr. James R. Bibbins, but unfortunately, when Friday afternoon came, no quorum could be obtained and no meeting was held.

DISCUSSION AT FUEL SESSION

(Continued from page 31)

not ideal conditions showed that over 60 per cent of the miscellaneous plants and 50 per cent of the chemical plants had an efficiency of less than 60 per cent. Analyses of the flue gases in these same plants showed that over 40 per cent of the chemical plants and over 65 per cent of the miscellaneous industrial plants had a very poor combustion efficiency, with less than 8 per cent of carbon dioxide present in the gas.

An estimate of efficiency and heat losses in the average boiler plant in the United States, reproduced in Technical Paper No. 205 of the Bureau of Mines, showed only a 57 per cent efficiency. A study of the situation shows that the efficiency should be increased to at least 67 per cent. Many authorities agree that the average efficiency may safely be considered as not over 60 per cent, leaving a large margin for possible saving in the average plant.

Willis Lawrence. The operator of the modern power house, even if he is familiar with the technical features of conservation, has little time to devote to experiments and tests to develop and maintain an efficient system of firing, so that the burning of fuel is not, as a rule, conducted on the highest plane of efficiency. Under such conditions the logical relief lies in supervision by a permanent outside organization which is in touch with the entire field of engineering, and has abundant research and test data, together with the practical experience which the individual plants can contribute. Such a source of help, whether federal, state or community, would be welcomed by the operators of fuel-burning plants, as it would relieve them from the burden and responsibility which they now carry. At the same time it would assist in a wonderful conservation of fuel.

Charles R. Schmidt. The first point in Mr. Myers' paper on fuel conservation, namely, the regulation of the quality of fuel, is perhaps the most important because it is "the foundation in the economical use of bituminous coal." The writer advocates the crushing and washing of all bituminous coal at the mines and suggests that the Federal Government furnish the crushers and washers to the operators, charging them 6 per cent on the investments plus the upkeep charges of the equipment, which would remain the property of the Government and in charge of the engineers from the Bureau of Mines. Also, as soon as enough mines are equipped with crushers and washers it should be made unlawful for anyone to sell or transport any but crushed and washed bituminous coal. We have a pure-food law; why cannot we have a pure-fuel law?

Oration in Memory of the Late Dr. John A. Brashear, Past-President of The American Society of Mechanical Engineers, by Dr. Henry S. Pritchett, President of the Carnegie Foundation for the Advancement of Teaching[1]

Adhuc scholasticus tantum est; quo genere hominum, nihil aut est simplicius aut sincerius aut melius.

I AM asked to speak before this body of trained engineers touching the scientific work of John Alfred Brashear. For nearly forty years I had the pleasure of his friendship and companionship. It is not easy under such circumstances to differentiate between those qualities in a man's life that pertain to his science or to his profession and those deeper and simpler relations that belong to friendship.

My purpose in speaking before this body of scientific men is not so much to tell the story of his life as to call attention to his contributions to optical science and research and his relation to some of those great forces in our social order which went to the making of a character like Brashear.

He was born almost exactly eighty years ago in what was then the little village of Brownsville, about thirty miles south of Pittsburgh. His father was a mechanic and the boy grew up under surroundings that intensified his natural aptitude for machinery. His mother's father was a watchmaker. From him the boy acquired not only his taste for technique of fine tools but he also imbibed from him early in life that love of astronomy which was perhaps his ruling passion.

Brashear's formal education was obtained in the public school of Brownsville which he attended until he was about thirteen years old, when it became necessary for him to earn his own living. Accordingly he went to Pittsburgh, learned the patternmaker's trade, and sought employment in one of the steel mills where he remained for twenty years, developing into an expert mechanic and becoming, toward the end of this period, the superintendent of a rolling mill.

During this period of his life as a practical mill mechanic he was under two strong influences, the one appealing to the spiritual side of his nature, the other to his intellectual side. He was a devout member of the Methodist Church and having a facility in public speaking he came to take an increasing part in the religious exercises of his denomination, until finally he came to believe that his path of duty lay in the ministry.

Side by side with this absorbing and insistent motive there grew up in his life another equally insistent and equally influential source of action. Early in his mill days Brashear had acquired a small refracting telescope. With this modest instrument he observed the moon and the principal planets, some of the star clusters and nebulæ. These views merely whetted his thirst and he began to long for something better than this small and inferior objective. Having no money there was but one way to get it and that was to make it himself; and so in the little shop at the back of his house, he and his wife began the grinding of a five-inch refractor. The story of this refractor has often been told.

These two motives, a deep and fervent humanitarianism and a passionate devotion to science were to be the dominant influences of his life. He never gave himself wholly to either the one or the other. Always he was the humanitarian, and always he was the man of science. Doubtless the impulse toward both of these lines of action arose from the same thing—the possession of a keen and ardent imagination. We do not always realize that the vision of human destiny and human progress that brings men with complete devotion into the service of their fellow-men is closely akin to that other vision of the forces and operations of nature, whether exercised upon the molecule or upon the stars, which also brings men irresistibly into the service of knowledge. Imagination, keen, far-sighted, sympathetic, may equally well lead its possessor into the one path as into the other. With Brashear it was a question hard to decide whether he should travel his life journey by the one way or by the other.

[1] Delivered December 8, 1920, at the Annual Meeting of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, New York.

It seemed at one time of his life that he had definitely turned toward the ministry. His intention to be a Methodist minister was publicly announced. On one or two occasions he undertook to conduct formal service, but in the end he convinced himself that he was a better mechanic than he was a preacher, that he could serve God better as a layman than as a minister. In the meantime the lure of the telescope was drawing him more surely into the service of science. It needed only the association with Langley to make him a lifelong worshipper at the altar of science, equally inspired by the beauty of the planets and the perfection of a prism.

Encouraged by Langley's praise of the five-inch lens, Brashear immediately began in 1875 a twelve-inch reflecting telescope which he completed in 1877 and which he used for some three years afterward in a study of the lunar crater Plato. During these years also Brashear became more and more the mechanical and optical assistant of Langley in his reseaches on radiant heat.

It was a fortunate chance that brought Langley, the astronomer, and Brashear, the mechanician, to the solution of a common problem, a process that also knit two great souls in a lasting and devoted friendship. To the men of our day, living amid the engrossing and insistent demands of civilization as it has developed in the last fifty years, it is not easy to picture the scientific enthusiasms that made possible in that day an astronomical observatory in the City of Pittsburgh, and which furnished at the same time the inspiration of a technician like Brashear and of an astronomer like Langley. The rise of the Allegheny Observatory is a part of the romance of the astronomy of the middle half of the nineteenth century.

Between 1840 and 1860 there was a popular passion for astronomy that was widespread, which took hold upon the imagination of the people of the United States as perhaps no other science has ever done. This enthusiasm had its origin in two things. The improvement of the telescope and of the optical means for the manufacture of telescopic lenses and mirrors had resulted in the interesting discoveries of Herschel, in the invention of the spectroscope and had aroused the general expectation that the telescope would soon reveal new wonders of the heavens to the eyes of men. Furthermore, in that day most of the information in regard to science was disseminated through the medium of public lectures. The all-pervading newspaper had not come to dull the thirst for knowledge and to satiate the curiosity for news.

This popular interest in the science of astronomy was greatly quickened by the appearance of Donati's comet in 1858. This was one of the most glorious heavenly visitors that have ever come within human ken. At its brightest the comet reached from the zenith to the horizon and the nations of the world gazed at it with awe and admiration.

The establishment of the Allegheny Observatory was a part of the romance of this movement. In February, 1859, in the glow of the enthusiasm created by Donati's comet, a few citizens came together to consider the purchase of a telescope which in their own language "should have the magnifying power which would bring the heavenly bodies near enough to be viewed with greater interest and satisfaction." The association was called in its earlier days the Allegheny Telescope Association, but it did not attain its object until after the expiration of ten years when it found itself in the possession of a telescope of thirteen inches aperture, at that time an instrument of extraordinary power.

I have dwelt with some length on the astronomical enthusiasm of the period between 1840 and 1860 and of the founding of the Allegheny Observatory because in this movement and in the founding of this observatory lay the forces which transformed John Brashear from a skilled mechanic into a maker of great lenses and the perfecter of the most delicate instruments of spectrum analysis.

When Brashear brought to Langley in 1875 his little five-inch

lens, Langley was engaged in a research into the problem of the selective absorption of radiant heat. Astronomy at that day was just beginning to turn from the old astronomy, which concerned itself with a right ascension and declination of stars, their proper motion, and their distances, to the study of the physical nature of the sun and of the stars made possible by the invention of the spectroscope and the gradual advance of photographic art. To carry on such researches as Langley was engaged in, there was needed not only a telescopic lens but also the most refined and delicate mechanical instruments. When Langley gave his kindly welcome to the mechanician Brashear with his imperfect lens, he had little reason to suspect that he was to find in him a coadjutor whose coöperation was to make his work glorious in the annals of astrophysics. Brashear became his indispensable aid.

Between 1875 and 1880 he had made a number of pieces of apparatus for Professor Langley to be used in connection with his study of radiant heat. By that time he had become so interested in these problems that he gave up his work in the steel mill and began making telescopic lenses and mirrors as well as other optical apparatus in his own shop established in 1880.

His first great success was attained in the silvering of the mirrors for Professor Langley's Mount Whitney expedition in 1881. His next achievement in Langley's researches was the invention of a method for polishing rock-salt prisms. Rock salt crystallizes in cubes. It has the remarkable property of transmitting heat rays and was therefore specially adapted for Langley's researches in radiant heat. On account, however, of its softness and its dull color it is difficult to obtain prisms or lenses that will take a high polish. Brashear overcame all these difficulties and produced rock-salt prisms and lenses which were not only used in Langley's researches but were immediately adopted by European astrophysicists.

About this time also he became much interested in the work of Professor Rowland of Johns Hopkins. The spectrum studied in the spectroscope is produced by a dispersion of rays of light in passing through a series of prisms due to the varying refraction of light of different wave lengths. Soon after the discovery of the spectroscope and the adoption of the undulatory theory of light, it was found that a spectrum resembling the prismatic spectrum could be produced by the diffraction of light waves from a ruled surface, the difference in the light phase being proportional to the number of rulings. Professor Rowland in the effort to perfect a machine capable of making a great number of lines on a hard surface so as to obtain gratings suitable for determination of the lengths of the light waves invoked Brashear's assistance. After a year of hard work he succeeded in overcoming the mechanical difficulties and Professor Rowland was able to rule gratings containing many thousands of lines to the inch.

In 1885 Brashear completed his first large spectroscope and in 1887 he completed what was then the greatest spectroscope of the world for the Lick Observatory, with which Professor Keeler made his famous investigations on the motion of the nebulæ in the line of sight. Other great spectroscopes followed in the years immediately succeeding. About this time also Brashear became interested in the work of Professor Michelson on the determination of the velocity of light and also on the measurement of velocities as existing between long and short waves. His aid was enlisted in the first refractometer which was used to measure the meter of the International Bureau in terms of light waves. He succeeded in reducing the limiting error of the optical surface to less than 5/100 of the wave length, a marvelous achievement in optical construction.

In the early nineties Brashear constructed for Prof. George Hale the first spectroheliograph for the automatic photography of the surface and surroundings of the sun. This work has been epoch-making in the realm of solar photography.

Meantime in his optical works Brashear was constructing objectives and mirrors for reflecting telescopes and for refractors of larger and larger aperture. Among the largest of these are the 16-in. refractor of the Carleton Observatory, the 18-in. refractor for the Lowell Observatory, and finally the 30-in. Cassegrain for the Allegheny Observatory, completed some ten or twelve years ago, and the 72-in. reflector for the Dominion Observatory at Victoria. He succeeded the Clarks as the great lens maker of America, but unlike them his marvelous mechanical knowledge and skill extended to almost every field of solar investigation. As the Clarks were the representatives of the old astronomy in the manufacture of great refractors, so Brashear became the representative of the new astronomy in the realm of mechanical and technical advancement. There have been in America three manufacturing firms who have had a notable part in the advancement of astronomy and stellar physics—Alvan Clark and Sons of Cambridgeport, the makers of the great refractors; Brashear and McDowell of Pittsburgh, also makers of lenses and of mirrors, but preëminent in the making of delicate prisms and tools needed in the new astronomy; and, finally, Warner and Swasey of Cleveland, the engineers of both the old and the new astronomy, whose designs and constructions have made possible the telescope tubes and the great installations necessary to operate the modern telescope with its spectroscope and photographic attachments.

Among Brashear's many achievements in aid of astronomy was the manufacture of photographic doublets designed to photograph in a single exposure a wide field. Among the most ingenious of these instruments were the great cameras made for Dr. Max Wolf of Heidelberg which were used for the photographic discovery of asteroids.

In the days between 1840 and 1860 when Brashear received those deep impressions which centered his interest upon astronomy, asteroid hunting was a favorite sport of the astronomer, and the discovery of an asteroid brought fame to the finder. In that day the discovery and the pursuit of these little planetoids was purely the work of the mathematical astronomer working with the ordinary refractor. It would have been a bold prophet who could have foretold fifty years ago that a highly trained mechanician and technologist like Brashear would have anything to do in the discovery of these little planets between Mars and Jupiter, but the wonderful photographic cameras which he made for Dr. Wolf were so effective that they quickly superseded all other means of asteroid hunting.

Brashear as a scientist, therefore, stands as the great technician of the new astronomy. His lenses, his mirrors, and his prisms, his gratings and his stellar cameras made possible those refined observations which have opened a new chapter in our knowledge of the physical conditions of the stellar universe. Astrophysics is not different from other physics except that it studies the physical properties of highly heated bodies millions of miles away. The lens of the telescope is only an incidental part of the apparatus used and the great results are gained by the perfection of those delicate instruments which are able to recognize a small displacement of an absorption line in the spectrum of the sun, of the stars and of the nebulæ. Brashear's scientific fame rests on these great achievements. He stands in the history of science as the master mechanic of the new astronomy.

The last fifteen years of Brashear's life saw him turn once more to the passion of his earlier years. With him the humanitarian and the scientific imagination had lived side by side and in his last years, and particularly after the death of his faithful wife, the old passion for human brotherhood once more became the dominant factor in his life. His work as Chancellor of the University of Pittsburgh, as administrator of Mr. Frick's gift for the teachers of Pittsburgh, and his untiring service to the Carnegie Institute and the educational interests of Pittsburgh was the expression of the devotion which had always been a part of his life and which became in his last years the moving force of his existence. Into all this work he threw a devotion and a sweetness of personality which made him a power in increasing and deepening those forces in education that made for good will and right living and earnest devotion. He did not pretend to be an expert in the organization or direction of formal education, but he was a missionary of kindliness and human service to those who wrought in formal education. After one of his astronomical lectures to the West Point cadets a very discriminating listener, himself an astronomer, said to Brashear, "Those boys will soon forget what you have said to them about astronomy but they will never forget you." It was a true word. Brashear's service to education was the gift of his own personality alive with the twin passions for science and for humanity.

Recent Papers Relating to Marine Engineering

PROGRESS IN OIL-BURNING PRACTICE IN THE NAVY AND MERCHANT MARINE

Recent Advance in Oil Burning, Ernest H. Peabody, Mem. Am.Soc.M.E. In the field of oil burning, as in many others, it is the U. S. Navy that is pointing the way to future developments. While oil burning has been and is extensively used in the merchant marine, it is carried out by means of comparatively small units both at the boiler end and at the oil-burner end. In fact, the author states that there is probably no single oil burner in the merchant marine capable of atomizing over 600 lb. of oil per hour, while the oil burned per hour per square foot of heating surface under forced-draft conditions is under one-half pound. This means that the full value of the use of oil fuel has not yet been approached and while savings and advantages in the use of oil fuel have been realized, all the possibilities of it have not yet been reached. For this there are good reasons, one of the most important being the fact that oil fuel has been applied to Scotch boilers and the above figures marked practically the limit to which such boilers may be forced with safety. Furthermore, certain limitations in the design used in the merchant marine are imposed by the existing types of condensers and evaporators.

In marked contrast to this the Navy Department is making rapid advances of an important character. In fighting ships it is now using water-tube boilers entirely, with improved condensers and evaporators, and the oil burners have been brought to a point where in recent tests it proved possible to atomize more than one ton of oil per hour per burner.

This apparently sounds the doom of the Scotch boiler. In the near future instead we shall have large economical water-tube boilers installed in closed firerooms, burning oil and operating under forced draft with a few large-unit mechanical atomizers.

A series of interesting tests were recently carried out at the Navy Fuel Oil Testing Plant using a small-tube express-type water-tube boiler of the White-Forster design, built by the Babcock and Wilcox Company and containing 7565 sq. ft. of heating surface and 753 sq. ft. of superheating surface, the furnace volume being 751 cu. ft. Three different types of air registers were used, two of the Bureau of Engineering with forced-draft and natural-draft design, and one Peabody register of the Babcock and Wilcox Company on which either forced or natural draft could be used.

The data of these tests are given in Fig. 1. In the tests of June 10 there were 11 boilers in operation, each atomizing 1032 lb. of Navy standard oil (25.5 deg. B.) per hr., giving a consumption of 1.5 lb. of oil per sq. ft. of heating surface per hr. The evaporation of water per pound of oil from and at 212 deg. fahr. was 15.14 lb., giving an evaporation of water per sq. ft. of heating surface per hr. of 22.73 lb. from and at 212 deg. with an efficiency of 76.15 per cent. The air pressure in the closed fireroom was 9.5 in. and the rate of combustion per cubic foot of furnace volume reached the very high figure of 15.12 lb. of oil per hr. It is believed that this test stands as a world's record for efficiency at high boiler and furnace capacity.

The record of 1032 lb. of oil per burner per hr., however, has been already outstripped in tests made on an enlarged type of the Babcock and Wilcox air register with mechanical atomizers which proved actually capable of atomizing over 1500 lb. of oil per hr. under conditions similar to those in the U. S. scout cruisers now under construction; and even this record was exceeded when, in a test of a Normand boiler at the Fuel Oil Testing Plant, Peabody-Fisher wide-range mechanical burners atomized over 1800 lb. of oil (crude Mexican of 13.3 deg. B.) per burner per hr., without smoke, carbon or other objectionable conditions. In these tests the oil burned per sq. ft. of heating surface was 1.2 lb. per hr., and per cu. ft. of furnace volume, 11.15 lb. per hr. It is claimed, however, that a record of atomization at the rate of 2287 lb. per burner per hr. has been attained for a short time.

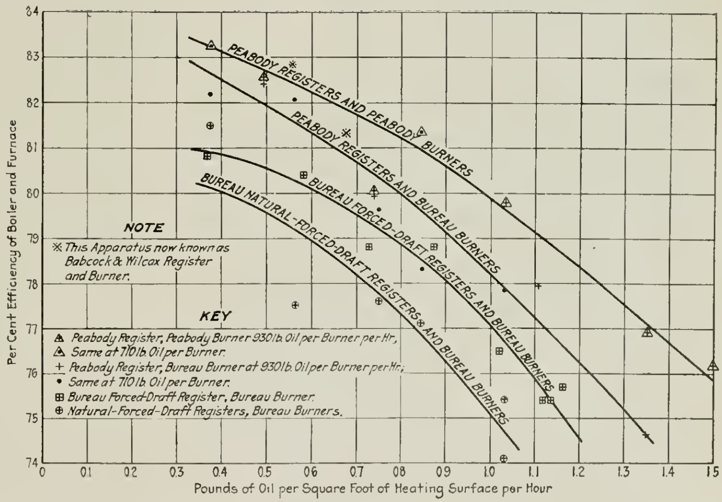

Fig. 1 Data of the White-Forster Boiler Tests Carried out at League Island Navy Yard Fuel-Oil Testing Plant

In this connection attention is also called to Fig. 3 giving data of one of the tests on a White-Forster boiler in which efficiency for boiler and furnace, in per cent, is plotted against boiler output.

These tests are too recent to make it possible to foretell their precise significance, but they point to important possibilities such as the use of a few very large boilers to obtain great outputs of power. Mr. Peabody expresses the conviction that the large unit both in boilers and oil burners has come to stay and that the trend of modern development is certainly in the direction of larger units and the higher capacities made possible by the use of fuel oil.

An important development in the design of oil burners has been that of making their operation more flexible. The mechanical atomizer of the usual design has a decided limitation in range, as it cannot be operated at low capacity if it is designed for a high one. The lower limit with the oil pressures ordinarily used is approximately one-half the upper. The reason for this is that the burner depends for its atomizing effect on the centrifugal force induced by giving the oil a rapid whirling motion in the central chamber of the tip. This whirling motion, in turn, is produced by delivering the oil to the central chamber through eccentric passages or

small channels substantially tangential to the walls of the chamber. As the capacity of the burner is reduced by reducing the oil pressure, the velocity through the channels decreases and friction losses grow until finally the spraying effect is reduced to the point where the oil issues from the tip in a solid stream or in a spray too coarse and excessive to give the desired results.

In the Thornycroft atomizer the size of the tangential channels may be reduced by an adjustment in the burner. This gives a greater flexibility to the burner, but it has been found difficult in practice to make individual adjustments under service conditions. The only other procedure, namely, to shut off some of the burners at low powers, or to change the size of the tips, or to do both, can be followed, but is open to objections.

Another and radically new plan, however, has been devised, which promises very satisfactory results. This consists in maintaining the whirling motion in the central chamber of the tip undiminished, whatever may be the capacity desired of the burner

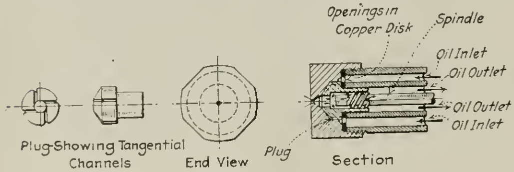

Fig. 2 Fisher Burner Used in U. S. Navy

in other words, instead of delivering through the orifice all the oil which enters the burner chamber, as is invariably done in all other mechanical atomizers, a part of the oil supply is diverted or bypassed from the central chamber and returned to the pump suction, and the actual effective capacity or amount of oil which is sprayed into the furnace depends merely on the proportion of the oil that is bypassed to the total amount entering the burner. Thus, as the amount of oil entering the central chamber through the tangential

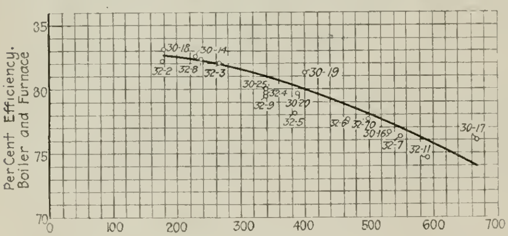

Fig. 3 Efficiency vs. Boiler Output, White-Forster Boiler

slots remains at all times at the maximum, the whirling of the oil and the atomizing effect remain also at a maximum, so that a perfect spray is secured whatever the capacity, at low powers as well as at the highest rate. By this method the range of the atomizer is very greatly increased, and, instead of being limited at the low powers to 50 per cent of the maximum, a good spray can be secured all the way down to about 10 per cent of the total.

This method of spraying is the invention of Commander J. O. Fisher, U. S. N., now fleet engineer of the U. S. Atlantic fleet. He first applied it in an attempt to spray oil into the cylinders of an internal-combustion engine, where, owing to the intermittent action required, the ordinary mechanical atomizer was an entire failure. By introducing the bypass a continuous flow was secured, even when the regular outlet orifice was closed. The application of the principle to atomizers for boiler work followed, with the result that a single burner without change of tip could be used over a greatly extended capacity range. The Navy Department has applied the Fisher burner with great success to small boilers of the launch type, where its wide range enables them to operate the boiler with only one burner. The author shows the navy design of this burner in Fig. 2. The company with which he is at present connected has developed a modified form of the Fisher burner with which some interesting experiments have been carried out with the coöperation of the Navy Department. It is believed that the wide range in capacity will make the burner especially useful for fluctuating loads or in any installation where it is now necessary to change the tips or close off a portion of the burners.

It may be of interest to state that the burners having a maximum hourly output of 1820 lb. which were tested at the Fuel Oil Testing Plant were successfully operated at 250 lb., while smaller tips designed for a maximum of 800 lb. were operated at a minimum of 80 lb. per hr. In the design described by the author the spindle shown in Fig. 2 has been dispensed with and the capacity is controlled entirely by an external valve in the bypass return line, so that by the manipulation of this valve any number of burners can be simultaneously increased or decreased in capacity over the entire range. Also, the tangential channels and the outler orifice are in a single piece. (Abstract of paper read at the 28th general meeting of the Society of Naval Architect and Marine Engineers, New York, Nov. 11–12, 1920.)

TESTS ON METHODS OF INJECTING FUEL OIL IN DIESEL ENGINES

Some Experiments in Connection with the Injection and Combustion of Fuel Oil in Diesel Engines, Prof. C. J. Hawkes. Data of experiments carried out with solid-injection and air-injection systems.

The solid-injection tests were carried out on a single-cylinder four-stroke engine in the Admiralty Engineering Laboratory. The engine is fitted with the piston of an aluminum alloy, has a cylinder diameter of $14^1/_2$ in., a stroke of 15 in. and develops 100 b.hp. at 380 r.p.m. The solid-injection fuel valve used during most of the experiments was of the direct-lift type, that is, the fuel-valve spindle which passed through a gland was operated directly by the fuel-valve lever.

The fuel used was shale fuel oil having a viscosity of 43 sec. at 70 deg. fahr. (Redwood No. 1). Because of the use of very small holes in the sprayer the oil was carefully strained through strainers fitted both on the suction side and on the discharge side of the fuel pump, the latter between the pressure gage and the fuel valve.

One of the objects of the experiments was to ascertain the effect of varying the bore and size of the holes in the solid-injection sprayer.

The first sprayer used was provided with five holes 0.019 in. in diameter and was similar in design to the sprayers fitted in submarine engines in 1914.

Next, the sprayer shown in Fig. 1 was tested. Here the fuel sprays were passed over the heated surface and each of the five holes was surrounded by a steel trumpet expanding from 1/16 in. to 3/16 in. in three-quarters of an inch. As the fuel valve in the experimental engine was inclined to the axis of the cylinder, a large portion of some of the trumpets had to be cut to allow the fuel valve to enter the cover. This modified sprayer did not prove successful and gave only 65 b.hp. When the valve was removed and examined, it was found that the interior of each trumpet was quite clean and bright, but there was a considerable carbon deposit on the external surface. Apparently the jets of oil had been striking the inner surface of the trumpets and it was decided to ascertain the effect of increasing the size of each trumpet so that it expanded from 1/8 in. to 5/16 in. in three-quarters of an inch. This alteration resulted in increasing the power to 95 b.hp. at 380 r.p.m., but after 40 min. running the power dropped to 90 b.hp. An examination of the trumpets showed that the jets had again been striking the sides and dribbling had occurred. The color of the trumpets also indicated that they had been comparatively cool and had not reached the red heat. The design was therefore abandoned.

Several tests were then made with sprayers provided with holes smaller than the standard 0.019 in. With 0.016-in. holes good results were obtained with an appreciable decrease in fuel as compared with the larger holes. Tests were then made with fitting steel plates to the top of the aluminum-alloy piston.

It did not appear, however, that the plates assisted combustion

either. The unsatisfactory results with the use of plates on top of the aluminum-alloy piston were apparently due to delayed combustion and possibly to some of the particles of fuel oil assuming the spheroidal state on striking the hot piston, thus delaying vaporization and combustion. On the other hand, however, in tests where heavy petroleum oil was allowed to flow in drops through a distance of about 6 in. on a heated steel plate, it did not show a clear spheroidal state. In tests, however, with shale fuel oil at about 250 deg. fahr. the drop of oil on reaching the plate broke into a number of smaller drops and assumed the spheroidal state. The occurrence of this state was observable until the plate reached a temperature of 600 deg. fahr. which was the highest temperature required in the tests.

If any portion of the injected oil assumed a spheroidal state on reaching the piston there would be a slight delay in combustion and the question of what proportion of the fuel oil which reached the piston remained in contact with it is discussed in detail by the author, who comes to the conclusion that both increased fuel consumption and delayed combustion with the hot plates may have been due either to the oil globules which assumed a spheroidal state on reaching the piston or to very rapid vaporization. This latter would appear to be an ideal condition so long as it is accompanied by good distribution.

Tests of variable fuel-injection pressures have shown that up to a certain point increase of pressure slightly reduced fuel consumption, but increase in fuel-valve roller clearance beyond a certain point did not give any better results and it was also noticed that the fuel-valve roller did not follow the contour of the cam.

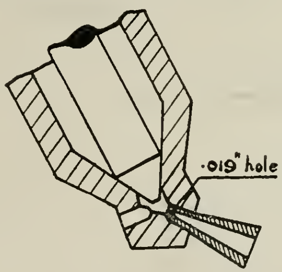

Fig. 1 Experimental Nozzle for Solid-Injection Marine Diesel Engine

Because of the lack of space the various valve-lift diagrams reproduced and discussed in the original article cannot be used here. Attention is directed, however, to Fig. 3, which presents the data of tests on fuel valve, cam, spring, etc., showing, among other things, under what conditions jumping of the fuel valve was likely to occur. Curve *a* represents the curve of velocity of opening and closing of the fuel valve; curve *b* the forces necessary to accelerate and decelerate the valve, etc.; curve *c* the load due to a 618-lb. spring; and curve *d* the spring load available after deducting the force necessary to accelerate or decelerate the valve and its operating gear.

Curve *e* represents the unbalanced oil pressure on the valve on the assumptions that the full pressure is acting during the opening and closing periods of the valve, and that the pressure drops uniformly in the system from 4500 to 3500 lb. per sq. in. The former is not of course correct for all positions of the fuel valve, but the latter is approximately correct. Curve *f* shows a similar curve, but its assumes that the pressure in the system drops uniformly from 3000 to 2000 lb. per sq. in.—which was the pressure for which the system was originally designed.

The critical period is undoubtedly when the valve begins to close, and if the full pressure acts on the underside of the valve during this period—and it probably does during the early portion of the closing period—it will be seen that the balance of spring load available to overcome gland friction is practically negligible with the higher fuel pressures assumed. Gland friction is acting

Fuel-valve gland friction is difficult to estimate in an engine running on service. In the case of the experimental engine it was ascertained that with the fuel-valve gland carefully packed (and tight) a force of 8.5 lb. was required to overcome gland friction (diameter of valve spindle, 7/16 in.). This should be regarded as being about the minimum figure. It will be seen that the 618-lb. spring provides only a small margin to overcome an increase in gland friction, or an increased fuel-oil pressure beyond that for which the system was originally designed. So far as spindle friction is concerned, the use of a "ground" fuel-valve spindle is an advantage—as a gland is then unnecessary. Difficulties following the adoption of higher pressures can be surmounted by fitting stronger springs or by a further modification of the design.

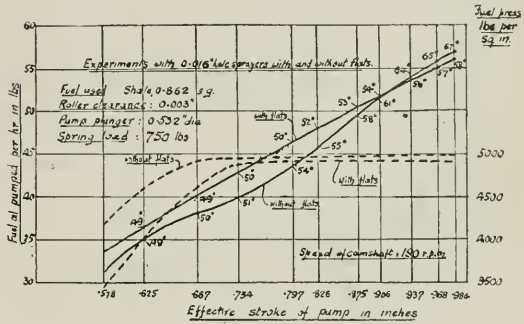

Fig. 2 Experiments with Sprayers of Different Lengths

Some interesting experiments were carried out with the object of ascertaining the effect of reducing the lengths of the holes in the sprayer on the quantity of fuel oil pumped and also on the pressures reached in the system. For this purpose a special apparatus briefly illustrated in the original article has been prepared. The tests were made and two sprayers drilled with five 0.016-in.-diameter holes, one fitted with flats in the vicinity of each hole, and the other without flats. The length of each hole in the sprayer with the flats is about $^1/_{32}$ in., or about half the length of the holes in the sprayer without flats.

The data of these tests are shown and plotted in Fig. 2, where the quantity of fuel oil pumped per hour (full lines) and the pressure in the system for each sprayer (chain-dotted lines) are plotted against the *effective* pump stroke—the fuel-valve spring being loaded to 750 lb. in each case. Against each recorded point is a number which represents the total period of opening of the fuel valve in degrees, obtained from fuel-valve lift diagrams. It will be seen that for the same effective pump stroke the quantity of fuel pumped is greater in the case of the sprayer *with* flats than in the case of the sprayer *without* flats, until the "jumping" of the fuel valve with the latter becomes excessive. It will also be seen that the fuel valve begins to "jump" when the pressure in the system exceeds about 4300 lb. per sq. in.

Similar experiments were carried out with these sprayers with a spring loaded to 900 lb. The effect of the stronger spring was to reduce the "jumping" of the valve with each sprayer, but the fuel pressures throughout were generally higher and the value of flats was more marked.

A large number of experiments were made with the sprayers under varying conditions, and the results may be summarized as follows:

1 It was noticed that the valve-lift diagrams obtained when the apparatus was barred round was shorter with a 900-lb. spring than with a 750-lb. spring—due to a slight deflection of the fuel shaft and lever at the increased spring load.

2 The difference between the quantity of fuel oil pumped when spraying into a cylinder filled with compressed air at 430 lb. pressure and when spraying, with the same sprayer, into the atmosphere was inappreciable.

3 When pumping the same *weight* of fuel oil, other conditions remaining the same, the pressure in the system when using Broxburn oil of 0.816 sp. gr. was slightly less than when using shale oil of 0.862 sp. gr.

4 It was thought that there might be a slight difference in the results with sprayers drilled with twist drills and similar sprayers drilled with flat drills. Two sprayers were therefore made similar in all respects, but the holes in one were drilled with flat drills 0.155 in. in diameter, and in the other with twist drills 0.01575 in. in diameter. The sprayers when tried in the spraying apparatus did not indicate any difference in the amount of fuel oil pumped, nor was there any difference found in the fuel pressure in the system.

5 The spindle friction of the valve used in these experiments was 15 lb., i.e., the valve required a force of 15 lb. to draw it through the packing with the spring removed. (The previous figure mentioned was $8^1/_2$ lb.)

SURFACE CONDENSERS FOR NAVAL VESSELS

Surface Condensers, Luther D. Lovekin, Mem.Am.Soc.M.E. There was a time when condensers were designed on a basis of so many square feet of surface per horsepower and this practice is still followed in some cases, though it is undoubtedly an unsatisfactory basis of design.

Tests made by the author of this paper have shown that other factors have a very vital influence on the performance of condensers, in particular, velocities of water and the steam space surrounding the tubes.

Thus, in tests made with a $^5/_8$-in. tube placed inside of other tubes of varying inside diameter, heat transfers with varying velocities of water and different tube layouts were obtained varying from 1000 to as high as 2750, this latter having been obtained when ample steam space was provided between the tubes.

These experiments also showed that it was a serious mistake to

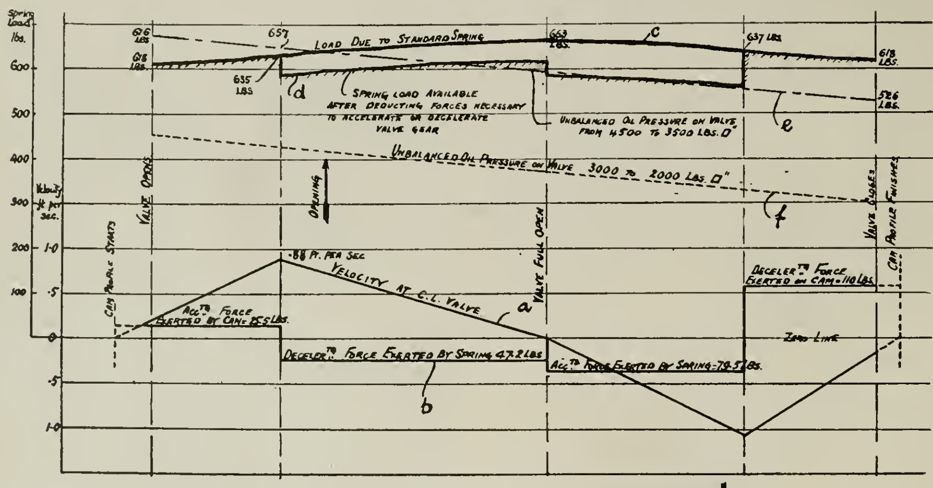

Fig. 3 Data of Tests on Fuel Valves in Solid-Injection Marine Diesel Engines

Closing

6 When the fuel pump was pumping with an effective stroke of $^{15}/_{16}$ in. against atmospheric pressure only its volumetric efficiency was about 95 per cent. The volumetric efficiency when pumping against the maximum pressure averaged about 75 per cent.

The conclusion to which the author arrives is that the success of the solid injection in service from the point of view of smokeless combustion depends very largely on the fuel-valve and fuel-pump design, correct settings, clean sprayers, and tight joints in the system. The best all-around results were obtained with a sprayer provided with five holes 0.016 in. in diameter. In general, however, the number and size of the holes in a sprayer depend on the mean pressure in the fuel-injection system; on the viscosity of the fuel oil; on the mean indicated pressure aimed at; on the distance the jets have to penetrate into the combustion chamber and also on the speed of the engine. The angle of the holes, i. e., the angle of the cone on which the holes are drilled, is dependent on the shape of the combustion chamber. So far as the author is aware, there are at present no formulas which can be used to determine the number, size and angle of holes necessary in a sprayer for a given engine to insure the best results—it is largely a question of trial and error.

The second part of this extensive and interesting paper cannot be presented here owing to lack of space, but it will be abstracted in an early issue of Mechanical Engineering. (Paper read before the North-East Coast Institution of Engineers and Shipbuilders, Newcastle-on-Tyne, Nov. 26, 1920, abstracted through an advance publication, 44 pp., 28 figs., *eA*)

fill up the condenser enclosure with an excessively large amount of tubes. Nothing could be gained by having the steam or condensed vapors traverse a mass of tubes after it had been condensed. Instead, the author recommended a design whereby a maximum inlet area between the tubes could be obtained so that with a volume of steam corresponding to a vacuum of $28^1/_2$ in., the velocity would be about 100 ft. per sec. or less. To do this, it was decided to reduce the depth of the bank of tubes to about half of that ordinarily used and to permit the condensate to be drained from said bank of tubes o its maximum temperature, approximately that of the temperature corresponding to the temperature of the vacuum.

An additional cooling chamber of liberal size was added to the condenser, the purpose of this being to condense any vapors that remained, the condensate from this area going into the common condensate space where it would be removed at the bottom of the shell. When used for battleships or the like, this air-cooling space was enlarged, providing about 40 per cent of the local tube surface. This enabled the outer portion of the condenser to serve as a primary condenser and the so-called air-cooling space as a secondary condenser. When the turbines are operating at less than full load, the primary condenser can do all the work and retain its heat in the condensate.

The design of the Lovekin condenser may be seen from Fig. 1. The air channel way is formed of two plates running the entire length of the space between the tube sheets, these plates being spaced apart and having their sides perforated with small holes over the entire plate. This is done so as to prevent any air pockets

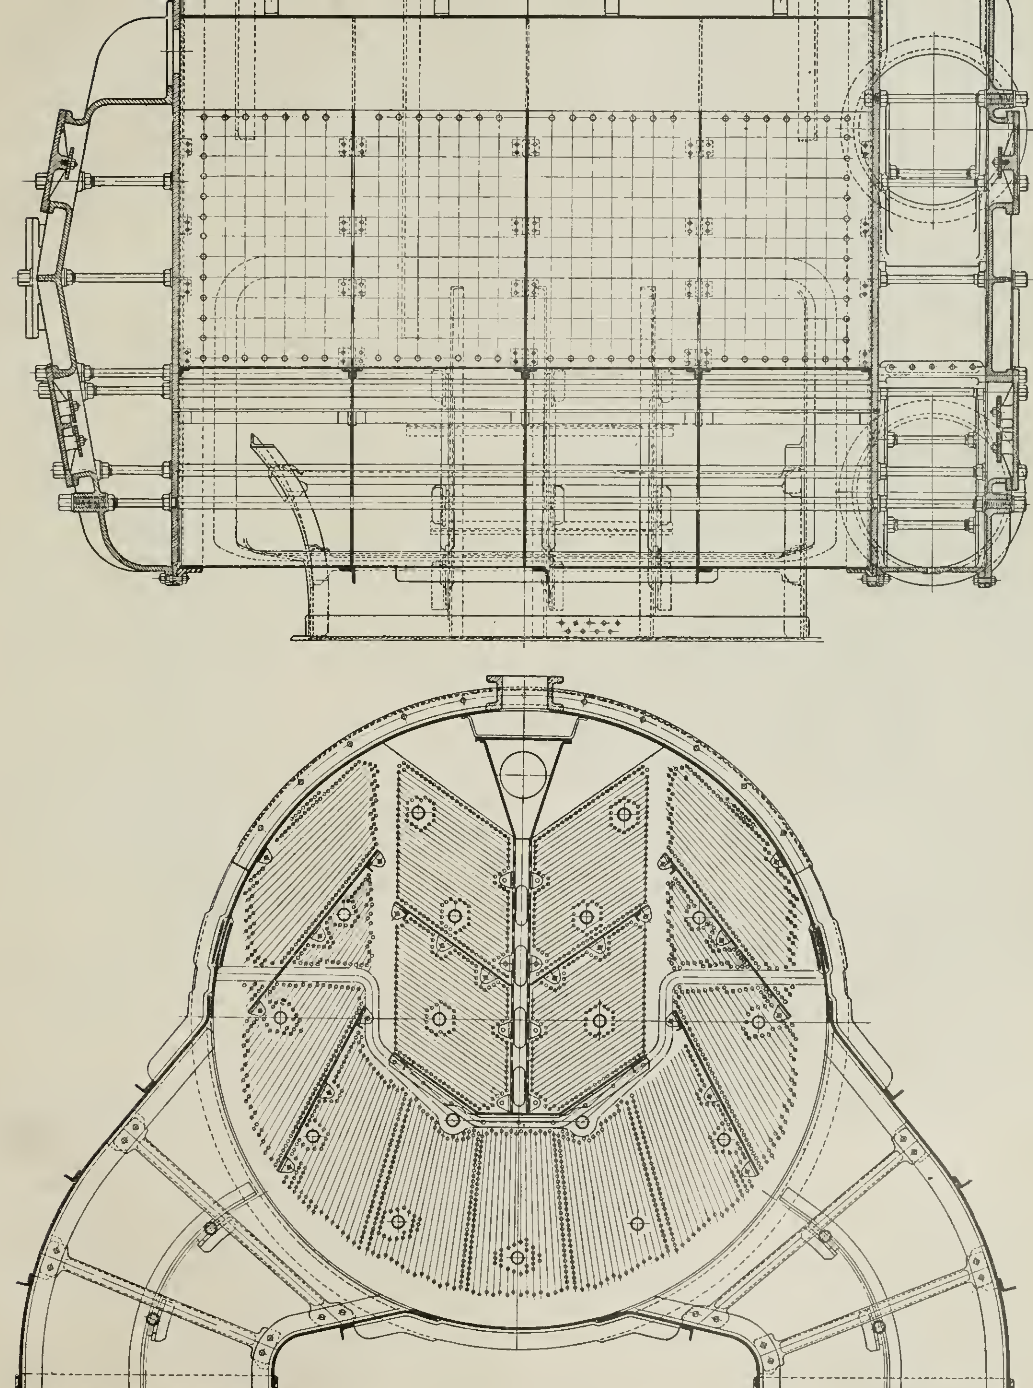

Fig. 1 Lovekin Surface Condenser

being formed in any part of the condenser. Where the condensate pump and air ejectors are used, the condenser head is cut away so as to clear the air-ejector connection. This makes a very simple connection and yet prevents the air pipe being flooded with water.

Small angle bars are placed in the lower edges of all the drain plates. These angle bars are not continuous but simply consist of short spaces with clear spaces of equal length between them so as to prevent the formation of a continuous sheet of water the entire length of the condenser running into the condensate space, which might interfere with the vapor and air entering the secondary zone.

In connection with the design of the Lovekin condenser, tests were made on the employment of coatings on the condenser shell as a means of preventing infiltration of air. These tests were made without any coating on the shell, then with one coat of bitumastic enamel, and finally with two coats of enamel. The effect of the final coat was an improvement of nearly 1 in. of vacuum under the same conditions. (Abstract of paper read at the 28th general meeting of the Society of Naval Architects and Marine Engineers, New York, Nov. 11–12, 1920.)

RIVETING FOR OIL-TIGHT WORK ON SHIPS

Notes on Rivets and Spacing of Rivets for Oil-Tight Work, Hugo P. Frear. The subject of proper riveting of oil tankers is a comparatively new one, as tankers themselves have scarcely been in existence fifty years. In fact, it is claimed that the first bulk oil-carrying steamer was built n 1872 in England.

Up to 1894 there were no definite rules laid for tanker construction by any of the national classification societies. In that year, however, Mr. B. Martell, chief surveyor to Lloyd's Register read a paper before the Institution of Naval Architects wherein he outlined his views on the details of construction and of riveting for bulk oil carriers. While not official, this paper served for a number of years as a guide to shipbuilders in the design and construction of tankers intended to be classed at Lloyd's. It is of interest to note, however, that the first rules of Lloyd's did not appear for general use until 1909, even though two other classification societies, the Bureau Veritas and the American Bureau of Shipping, had published their rules several years before. This is a good illustrat on of the slowness and care with which the great classification societies are accustomed to lay down their standards of construction.

In fact, judging from data presented in Mr. Frear's paper, it is doubtful if any standards of construction may be considered as having been definitely adopted even today. Thus, it would appear hat while double riveting is the general requirement for oil-tight work, single riveting is permitted in the seams of double bottoms intended for carrying fue oil. It is still uncertain, however, whether single-riveted seams are tight enough for gasoline, or whether, as some claim, they are even more suitable for gasoline than for crude oil, because of their tendency to rust up with gasoline.

In this connection the writer recommends as well worth considering the use of single riveting in the longitudinal seams of centerline bulkheads, with the exception of the lower seam. The cargo is sometimes made up of more than one kind of oil and it is therefore important that the transverse bulkheads be absolutely tight, but different kinds of oil have seldom been carried on opposite sides of the center line and it would appear that a single-riveted longitudinal bulkhead would fulfill every function that the trade demands

As regards spacing, a considerable latitude still exists. At first, Lloyd's recommended three diameters for all oil-tight spacing, but a spacing of five diameters is now allowed in connecting bulkhead bounding bars to shell.

In both the types of bounding bars and the methods of riveting a variation is still permitted, the builder having an option of using either single double-riveted bars or double single-riveted bars. Furthermore, the rivets sometimes are calked before testing and sometimes are left free from calking. A good pan-head rivet should not require calking before testing. It would appear that countersunk-head rivets may require it.

Coming back to the subject of spacing, it would appear that while in his time Mr. Martell was justified in recommending a spacing of three diameters for satisfactory oil-tight work improvements in design, construction and workmanship have demonstrated that stanch ships can be built with wider spacing. In merchant vessels converted to carry oil the spacing is generally $4^1/_2$ diameters in the shell. In determining spacing it is well to bear in mind that work which might be tight under a static head might work loose on parts subject to the working stresses of a vessel in a seaway. Any design, spacing or workmanship which will not permanently prevent the joints from slipping will not remain oil tight.

In naval vessels using oil for fuel special problems of design came up. In these, in some cases, longitudinal bulkheadsare used as strength members and the riveting should be such as to obtain maximum strength, which means that the spacing cannot be made too close, especially where the bulkheads form boundaries of oil tanks. Because of this, if the strength bulkhead is designed for a spacing of six diameters for rivets in stiffeners and oil-tightness demands five diameters at the transverse bulkhead, it becomes necessary to introduce compensating liners which add to the weight and also increase the difficulty of making the structure tight. At the same time, tests carried out at the Philadelphia and New York Navy Yards appear to indicate that in fairly heavy plating where the members are not under the influence of other stresses than those due to head, six diameters is suitable. The thickness of angle bars, it was suggested, should preferably be not less than $^3/_8$ in. The Navy has under contemplation the revision of its rules for oil-tight riveting, due to the very considerable increase in amount of oil-tight work involved by new construc ion.

So far in naval work a c oser spacing is demanded for oil-tight work than for water-tight work, though experience in the construction of oil tanks in double bottoms seems to indicate that with ordinary good workmanship water-tight spacing will be satisfactory for oil.

The following spacing has been proposed as meeting both leakage conditions and the stresses imposed by deflections caused by calking and water pressure:

Plate	15-lb.	20-lb.	25-lb.	30-lb.	35-lb.
Spacing in diameters	4	4.5	5	5.3	5 6

These values, however, have been deduced without reference to strength of joint.

From the general data presented by Mr. Frear in his paper it would appear that any riveting for oil-tight work is really a compromise between the desire to produce an oil-tight joint and the very important consideration that every unnecessary rivet is a possible source of leakage and also a source of weakness of the plates. (Abstract of paper read at the 28th general meeting of the Society of Naval Architects and Marine Engineers, New York, Nov. 11–12, 1920.)

Short Abstracts of the Month

BUREAU OF STANDARDS

The Carbonization of Lubricating Oils. The principal reason for writing this circular was to give detailed descriptions of the methods used for the determination of the "Conradson carbon residue" and the "Waters carbon" of oils used to lubricate internal-combustion engines.

After brief accounts of the nature and effects of "carbon" deposits in the engine, and of the chemical nature of petroleum oils, the theories concerning the causes of the deposition of this material are discussed in connection with somewhat detailed accounts of the oxidation and cracking of petroleum oils.

The Waters and Conradson tests are described in detail, together with the apparatus employed, and brief accounts are given of a few other methods, including those in which the oil is distilled.

The circular closes with a condensed summary of several more or less controversial papers that have been published elsewhere. (Abstract of Circular No. 99 of the Bureau of Standards, *e*)

the Institution of Mechanical Engineers covering experimental research on wire ropes for use over pulleys.

It does not appear that the Committee carried out any special experimental work of its own, but it very carefully collated all the available information and presented it in a clear form.

The conclusions arrived at are that there is no reliable information available as regards the factor of safety when used over pulleys. No sufficient data are available to establish a general method for the design of ropes, especially as entirely different problems present themselves in various installations. Thus, the outside wear is most important for a rope working on a large pulley, whereas bending fatigue and internal wear do most damage when a small sheave is used.

The calculation of the bending stress for design does not at present appear to be satisfactory. There is a lack of agreement on the factor to be used with the Reuleaux formula. There is no rational formula which covers the actual conditions and it has not yet been shown that the bending stress is the determining factor in the destruction of a rope. It is suggested that an attempt should be made at an analysis which will separate the three destructive effects: namely, outside wear, wear between the wires, and bending fatigue.

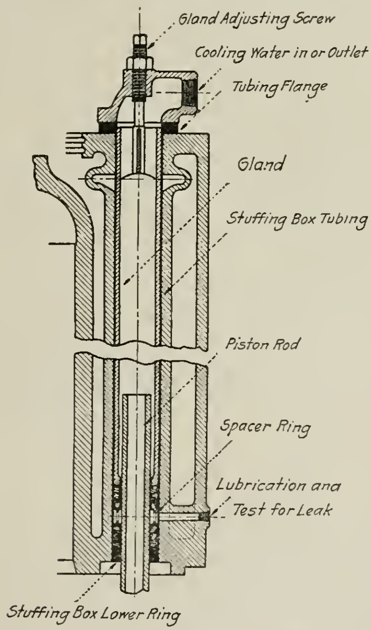

Fig. 1 Section through Power Cylinder of the Manning, Maxwell & Moore Marine Diesel Engine

Distinction should be drawn between hardness and tensile strength, which are generally regarded as increasing together.

The information concerning the wire diameter indicates a difference of opinion which was not expected. As regards the adjustment of the lays to suit the diameter of the pulley, some writers have asked for it, but there is no exact information which bears on this point. The balance of opinion favors Lang's lay, where it can be used, but the preference is not shown so clearly by American engineers.

The effect of different angles of bending of the cable over the pulley appears to be explained very clearly by Leffler, although some opinions are at variance with his conclusion. The formula he gives to calculate the true radius of curvature of the rope does not agree with that of the Trenton Iron Company.

pulleys there is scarcely a single element of design on which sufficient information is available and an agreement exists between engineers. To say the least, this is a very surprising state of things, considering the extensive and long use of such wire ropes. (*The Journal of the Institution of Mechanical Engineers*, no. 7, Nov. 1920, pp. 835–868, 1 fig., *gpA*)

INTERNAL-COMBUSTION ENGINEERING

Marine Diesel Engine with Peculiar Arrangement of Scavenging Pump and Piston Rods

Goldberg Double-Acting Two-Cycle Marine Diesel Engine. Description of an engine in which the scavenging pump is in two stages, the first stage serving for scavenging proper and the second stage for supercharging the working cylinder and also as the first stage for the injection-air compressor. With this arrangement the low-pressure injection cylinder requires not over 70 per cent over its displacement when using air at atmospheric pressure. The air-pump piston closes the scavenging ports ahead of its dead center for a distance, preventing the pump on its return stroke from filling again from the working cylinder.

This means that the scavenging port of the pump cylinder is not uncovered again until the working piston has covered the the scavenging ports of the power cylinder.

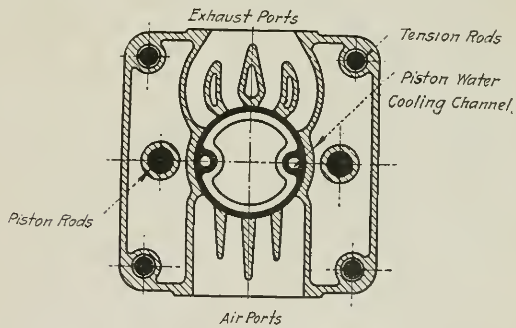

Fig. 2 A Large Section of Stuffing Box for Piston-Cooling Arrangement, Manning, Maxwell & Moore Marine Diesel Engine

To provide a better cooling of the pistons, the piston rods are extended into the upper cylinders and are drilled as shown in Fig. 1, one rod serving for water intake and the other for water outlet. The stuffing boxes proper for these sliding pipes (Fig. 2) consist of a light tubing with a collar at the bottom extending to the lower end of the cylinder casting. The packing is held between the lower collar and the gland in the form of a tube.

It is claimed that the double-piston-rod arrangement besides other advantages accomplishes also a great saving in the construction of the connecting rods. With this, the crosshead proper consists of a simple steel forging to which the crosshead shoes are fastened in a conventional way, but the forked type of marine rod is not used any more.

The four-cylinder 3000-shaft-hp. engine of this type has the following dimensions:

Bore	22 in.
Stroke	33 in.
Speed	120 r.p.m.
Piston speed	660 ft. per min.
Shaft mean effective pressure (m.e.p.)	66 lb. per sq. in.
Overall length, including flywheel, thrust block and air compressor	40 ft.
Overall height from center line of shaft	26 ft.

A shaft m.e.p. of 66 lb. per sq. in. is a very conservative figure. The low piston speed of 600 ft. per min. was selected with propeller efficiency in view. A shaft m.e.p. of 66 lb. per sq. in. can be obtained without surcharging the cylinders and the great over-

load capacity of this type of engine for forced runs of vessels may well be of great value. With surcharging and increasing the speed of the engine, say, to about 160 r.p.m., we can obtain 3000 shaft hp. for short periods, though it may not be advisable to carry this load through continuous days of service. (*Motorship*, vol. 5, no. 11, Nov. 1920, pp. 993–994, 3 figs., *d*)

FUELS AND FIRING

Initial Air Temperature and Economy of Furnaces

Influence of the Initial Air Temperature on Combustion Processes in Furnaces, J. Hudler. The question of the importance of higher initial temperatures of air supplied to furnaces is discussed and it is pointed out that this importance is much greater than is generally realized. Particular attention is paid to the relation between the entering temperature of air and the temperature of exhaust gases and rate of firing of the unit. In general, the problem of firing consists in the transmission of heat from rapidly moving gases of combustion to stationary solid or liquid bodies. The author claims that the processes taking place during this heat exchange are not always fully understood, and proves mathematically that to each initial temperature of air T_0 there corresponds a definite temperature of the exhaust gases T_1, providing the amount of heat generated per hour remains constant.

To show the bearing of this fact he compares two cases of combustion of pure carbon with a 6 per cent carbon dioxide content in one case and 12 per cent in the other, which corresponds to the change that occurs in passing from hand firing to automatic stoking with the better control of stack gases, and shows that if the rate of firing in the case of the 12 per cent CO_2 content be reduced to such an extent that the temperature of exhaust gases falls to 185 deg. cent., there will be a saving of 28.3 per cent in fuel, with undiminished output. Should, however, the gain in the CO_2 content be obtained by the usual method of decreasing the volume of exhaust gases, that is, maintaining the temperature of the smokestack constant, there will be a fuel saving of only 21.3 per cent. From this it would appear that the importance of higher content of carbon dioxide in the smokestack gases accompanied by a higher initial air temperature is greater than generally realized.

As to the means for securing a higher initial air temperature, the author points out that the heat contained in a cubic meter of exhaust gases must be considered as the basis for the initial temperature of the air and is fairly well proportional thereto, and therefore economically it is important to make the ratio W/V of heat in the air to heat in the exhaust gases as large as possible.

While such a requirement, however, is very simple theoretically, it is very difficult to solve the practical problems involved therein. In hand-fired grates immediately after the coal has been thrown upon the grate there is a development of gases with very high heat content which require large amounts of air for their combustion. As soon, however, as the process of volatilization is ended, and from that point on to the next firing, the air demand falls off. This difficulty is largely eliminated by modern automatic methods of firing in which coal is delivered on to the plate uniformly, and the air delivery may be maintained in a balanced manner proportional thereto. It is this that makes it possible to raise the content of carbon dioxide in the exhaust gases to 12 and even 14 per cent, which is so largely in excess of what could be done with hand firing. A still further opportunity to increase the content of carbon dioxide or to reduce the volume of exhaust gases is offered by producer-gas firing. While this method of firing has not proved hitherto entirely successful for boiler-operation purposes, this was mainly due to the fact that gas producers have considerable radiation losses which are further increased during the transit of the gases from the producer to the firing chamber, so that the reduction of V is offset by a simultaneous decrease in W. Furthermore, the usual addition of steam to the gas-producer air supply also increases V. It is therefore not correct to say that in view of fuel conservation our fuels should be utilized always in a gaseous state.

On the other hand, where producer-gas firing is used for purposes making necessary the employment of high smokestack temperatures, it is possible to raise the initial air temperature to a very high degree by preheating it, and therefore to increase the numerator in the expression W/V while maintaining the denominator unaltered.

The author asks the following question:

What gain is secured in preheating the air to 800 deg. cent. as compared with combustion carried on with air at zero deg. cent., maintaining the smokestack temperature at 1000 deg. cent. and operating with a 20 per cent excess of air?

The answer obtained is so surprising that it appears to be worth while to reproduce the calculation given in the article.

As during the combustion of one cubic meter of carbon monoxide 3046 kg-cal. are developed, the lower heat value of the gas is given by the expression

$$H_n = 3046 \times 0.347 = 1057 \text{ kg-cal.}$$

The combustion with the theoretical minimum of air produces 0.347 cu.m. carbon dioxide plus 1.306 cu.m. nitrogen. With an excess of air of 20 per cent there is added to this 0.261 cu.m. nitrogen and 0.069 cu.m. oxygen, which bring the total volume of exhaust gases to 1.983 cu.m.

The heat carried off by the exhaust gases is

$$W_R = 1000 \times (0.347 \times 0.501 + 1.636 \times 0.325) = 706 \text{ kg-cal.}$$

which means that the useful heat with cold air is equal to the initial heat of the gas (1057 kg-cal.) less the smokestack losses (706 kg-cal.) or to 351 kg-cal.

One cubic meter of gas, however, contains 1057/1.983 or 533 kg-cal., which gives an initial temperature of 1464 deg. cent.

On the other hand, with preheating of air we find that instead of the theoretical volume 0.826 cu.m., we have an increased volume of 1.156 cu.m. When preheated to 800 deg. cent. the heat content of this volume is

$$W_L = 1.156 \times 800 \times 0.32 = 296 \text{ kg-cal.}$$

which means that 1.983 cu.m. of smokestack gases carry the initial heat of 1057 kg-cal. and the heat added by the preheating of the air 296 kg-cal., or a total of 1353 kg-cal., equal to 682 kg-cal. per cu.m. of gases, which gives an initial temperature $T_0 = 1812$ deg. cent. It would appear, therefore, that for a temperature of preheating $t = 800$, the following equation expresses the conditions of equal output with and without preheating:

$$\frac{1464 - 1000}{l(1464 - 800) - l(1000 - 800)} = \frac{1812 - T_1}{l(1812 - 800) - l(T_1 - 800)}$$

from which T_1 can be found to be equal to 894 deg. cent. and

$$W_R = 894 \times (0.347 \times 0.504 + 1.636 \times 0.32) = 632$$

which gives the starting result, namely, that the useful heat is $1353 - 632 = 721$ kg-cal., or some 370 kg-cal. more with air preheated to 800 deg. cent. than with air at zero deg. cent., notwithstanding the fact that through preheating only 296 kg-cal. have been added.

In other words, the calculator shows that the increase in usefully employed heat is equal to 125 per cent of the increase of the heat content of the air.

Because of the fact that the initial air temperature has been raised, the smokestack temperature has been reduced and with it the smokestack losses have been reduced. The contention that the increase in efficiency produced by preheating the air of combustion is more than equivalent to the direct effect of the heat supplied to the air, is claimed to be a novel one, and it is further claimed that the same results are obtained if not air but the gas is preheated. From this point of view it can be seen how undesirable results are introduced by the usual cooling of gases in ammonia by-product recovery producers, apart from the fact that the large volumes of steam usually present in producer gas also act in the way of reducing the gas temperature and increasing the volume of the stack gases.

Other parts of this interesting article may be abstracted at a later date. (*Zeitschrift des Vereines deutscher Ingenieure*, vol. 64, no. 40, Oct. 2, 1920, pp. 810–814, 1 fig., *tA*)

Helical Springs, W. Norman Thomas. It has been observed that in practice many springs fail under smaller loads than those for which they were originally designed. Investigation shows that there are two considerations which may easily be overlooked in the design and use of a spring, namely, (1) the effect of eccentricity of the load, and (2) the effect of the direct shear stress as distinct from the torsional shear stress in the material of the spring. Failure may be due either to entirely overlooking these two points, or, more often, to underestimation of the magnitude of the applied loads and of the effects of impact and repetition of stress. In a considerable number of cases failure may be due to the fact that the springs were designed for normal-temperature work and then afterward employed under very high- or very low-temperature conditions.

Equations are developed for the design of close-coiled springs and open-coiled helical springs, and curves are given, among other things, showing the bending and twisting moments in various parts of springs for different eccentricities of load, and the maximum principal stress and the maximum shear stress at the extremities of the vertical diameter of the cross-section of the wire. From these equations it appears that for the same value of M (eccentricity) the deflection is smaller with an open-coiled spring

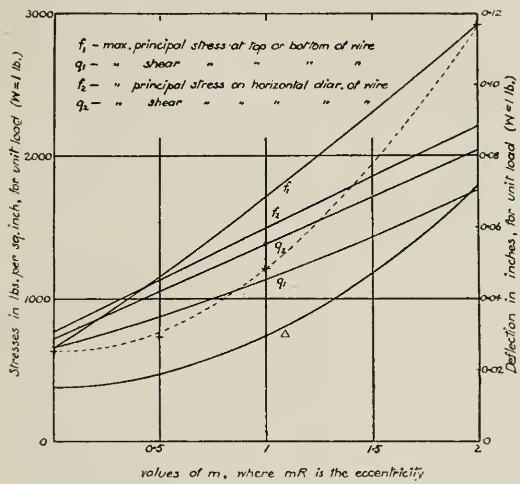

Fig. 3 Graphs of Stresses in the Wire of Helical Springs Calculated by Various Formulas

than a close-coiled spring containing the same length of wire. If the number of coils is the same for each spring, then for the same value of M the deflection is greater with an open-coiled spring than with a close-coiled spring. In addition to this, the values of the stresses in the wire calculated by the various formulas given in the article are tabulated and plotted in Fig. 3. From these it would appear that unless the load is axially applied upon a spring, the stresses may be considerably greater than those for which the spring was designed.

Thus, in an example worked out in the original article, 665 W would represent the load for which the spring was probably designed, that is, assuming axial loading and neglecting the direct shear stress; whereas the maximum shear stress even with axial loading is 721 W, and the maximum principal stress f_2 is 779 W.

With an eccentricity of $0.5R$, which could easily occur, the maximum shear stress is about 1053 W and the maximum principal stress f_1 about 1168 W.

If the eccentricity of the load is greater than $0.5R$ the stresses are still more in excess of the nominal safe load for axial loading. It is very important, therefore, that the ends of springs should be so designed as to insure axial loading. This is moderately

and therefore still further to increase the stresses.

Some experiments were undertaken in order to test the truth of the general formula for deflection obtained in the original article, and they have generally confirmed it. (*Journal of The Institution of Mechanical Engineers*, no. 7, Nov. 1920, pp. 869–889, 13 figs., *tpA*)

MEASURING APPARATUS

Measuring Lengths to Within 1200 of a Millionth of an Inch

The Ultra-Micrometer. Prof. R. Whiddington. Not so long ago working "to a hair's breadth" was considered quite an achievement. Then, the thousandth of an inch became a fairly common limit of precision in machine work, and a thousandth of an inch is only a fraction of a hair's breadth. It had been found, however, that in order to permit work to a thousandth

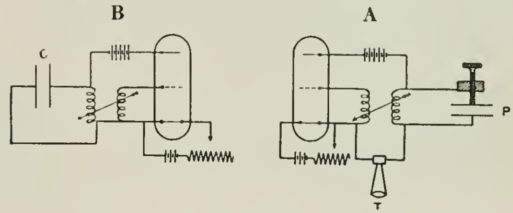

Fig. 4 Diagram of Main Electrical Elements in the Whiddington Ultra-Micrometer

of an inch the gages had to be made far more precise, and various methods, in particular the so-called interferometer methods of measurement, were developed, permitting a precision as high as one-millionth of an inch.

Interferometer methods, however, are limited in accuracy of measurement by the wave lengths of light used in the production of the fringes. It is not always easy to see at once where precision of measurement in excess of a millionth of an inch may be required, but in scientific work there are already cases where a higher precision is desirable. The ultra-micrometer, a new device, permits measurement to the scarcely creditable precision of one two-hundredth of a millionth of an inch. As an idea of what one two-hundredth of a millionth part of an inch means, it may be said that it bears very roughly the same relation to one inch that one inch bears to the distance by rail between New York and San Francisco.

The new measuring apparatus is based on the fact that if an electric circuit, consisting of a parallel-plate condenser and inductance, be maintained in oscillation by means of a thermionic valve, a small change in distance between the plates produces a change in the frequency of the oscillations which can be accurately determined by certain methods. The sensitiveness of the apparatus is extremely high.

The theory of the method is comparatively simple. If a capacity C be connected to an inductance L, the frequency of oscillation N natural to the circuit is given by

$$N = \frac{1}{2\pi\sqrt{LC}}$$

If the condenser be composed of two parallel plates of area A separated by distance x, then the capacity C is determined by the equation

$$C = \frac{A}{4\pi x}$$

If we substitute this value C into the above equation for N, we obtain

$$N = \left(\frac{x}{\pi LA}\right)^{1/2}$$

which shows that a change in distance x between the plates pro-

duces a change in the frequency of oscillations N, so that inversely a change N may be taken as an indication of a change in x.

On the basis of this theory was built the apparatus shown in Fig. 4. In this diagram A is the oscillating-valve circuit involving a parallel-plate condenser P; T is a loud-speaking telephone, shown for simplicity directly inserted in the valve-anode circuit, although in actual practice an amplifier intervenes.

The values of the coils in the grid and anode circuits of the thermionic valve were so chosen as to produce oscillations N of about a million frequency. In order to bring about any change in N a second valve circuit B was set up close to the circuit A. The frequency of this circuit could be adjusted by means of the condenser C so as to be nearly but not quite equal to N. This produced a loud audible note in T, the frequency of which could be adjusted to any desired value by a suitable choice of C. Another valve circuit was provided with proper capacities and inductance in order to provide a constant standard of pitch to which the note in T could be adjusted. This additional circuit is now shown in Fig. 4.

As regards the sensitiveness of the apparatus, it may be mentioned that the bending of a very substantial table, produced by an English penny coin laid on its edge, was clearly indicated by a change in the note from the telephone T.

The details of the method of measuring are not given. The method has been of service, however, by proving that Hooke's law was obeyed to the limits of accuracy set by a micrometer capable of measuring to 10^{-4} inch. (*London, Edinburgh and Dublin Philosophical Magazine and Journal of Science*, vol. 40, no. 239, Nov. 1920, pp. 623–639, 2 figs. and 1 plate of photographs, *dA*)

METALLURGY

New Method of Carbonization. Earl W. Pierce and John W. Anderson, Mem.Am.Soc.M.E. In this article the authors question whether the conventional method of carbonizing produces a tough core. They claim that the hardening of the outer wearing surface is produced at the expense of the core.

The treatment which they recommend to avoid this disadvantage is based on the idea of keeping the carbonizing temperature as near the first hardening heat as possible, or vice versa.

The method requires a lowering of the carbonizing temperature close to the core-refining heat, as it would not be practical to raise the hardening heat to the carbonizing temperature without danger of ruining the part. This method makes a longer carbonizing time necessary to produce the necessary depth of case, but this increased time is made up in the subsequent hardening heats.

Actually, the process is carried out in the following manner: The carbonizing temperature is lowered to that of the core-refining heat, namely, to 1600 deg. fahr., so that the carbonizing is carried on well within the carbonizing zone and at the same time at a temperature insuring as fine a grain as possible. When the work has become heated through at this temperature, it is quenched and the fine structure formerly produced in the carbonizing operation is trapped. It is well to hold the heat at the hardening temperature a few minutes to recover any crystalline growth which may have occurred in cooling after carbonizing between that temperature and the upper critical point of this kind of steel, which is about 1550 deg. fahr.

It is claimed that this method permits straightening with ease work distorted to some extent in hardening, and with practically no breakage loss nor cracking of the case-hardened surface. (*The Iron Age*, vol. 106, no. 21, Nov. 18, 1920, pp. 1315–1316, *dp*)

Important work is being done in the field of metallurgical applications of the so-called rare metals. During the war zirconium is said to have been extensively used in gun steel, as it imparts an increased hardness to the metal. In this country apparently successful attempts have been made to use cerium as a deoxidizer for cast iron. No metallurgical applications have yet been discovered for barium, strontium and beryllium, while lithium is used only sparingly in one or two special alloys.

MOTOR-CAR ENGINEERING

Steam Power Plants as Applied to Vehicles for Common Roads. F. L. Egan. Discussion of the application of steam power to motor vehicles, in particular passenger cars and trucks and covering English and American practice.

From data presented in the article it would appear that substantial progress in the direction of application of steam has been achieved in England where the high cost of gasoline makes the use of cheaper fuels with steam more attractive than in this country.

The two following facts are presented in reference to the practice of a large company operating motor buses in London. Although the company formerly operated gasoline- and kerosene-engine buses, it is regularly replacing the gasoline units with steam machines. Furthermore, in 1915, on steam-driven machines a change was made from kerosene to coke fuel, sufficient coke for about 50 miles being carried.

The larger part of the paper is devoted to the description of the Stanley and Doble-Detroit systems. As regards the probable trend of future developments, the author believes that the steam-generation and combustion system will be simplified, and states that a distinctly new type of boiler made possible by a new application of combustion is now in the experimental stage.

The engine, in the opinion of the author, will stand practically as it is, except that for the larger trucks it may be advisable to use a separate engine to drive each rear wheel through an internal gear on the road wheel meshed into a pinion on the end of a short crankshaft, which would do away with differential-gear and live-axle troubles. (*Proceedings of the Engineers' Society of Western Pennsylvania*, vol. 36, no. 7, Oct. 1920, pp. 455–484, and discussion pp. 485–491, 23 figs., *g*)

FUELS AND FIRING (See Producer Gas)

INTERNAL-COMBUSTION ENGINEERING (See Producer Gas)

PRODUCER GAS

British Practice in the Operation of By-Product Plants for Power Purposes

Notes on Operating a By-Product Producer-Gas Plant for Power and Heating. Description of a plant built for the Hoffmann Manufacturing Co., Ltd., in England, and operating on the Lymn system. The plant is in two units of 30 tons capacity each and is intended to have by-product recovery.

In a plant of that character it is very important to prevent the destruction of ammonia, which means that large quantities of steam have to be introduced with the air into the producer; this has the effect of facilitating the formation of ammonia and preventing its destruction by keeping the temperatures in the producer comparatively low. From 2 to $2^1/_2$ lb. of steam per pound of coal gasified may be taken as an average figure, and the provision of so much steam is a serious item in the cost of production. In the plant described the method adopted is to cool the gases by contact with water and heat up and saturate the air with the hot water so obtained. The process is continuous and results in having approximately 0.75 lb. of steam picked up by the air for every pound of coal gasified, which corresponds to a temperature of 68 deg. cent. (154.4 deg. fahr.) saturation. The balance of steam required is obtained from a boiler plant in which a superheater is included for steam required in the plant for other purposes outside the gas installation. It was found, however, when superheated steam was used for the gas plant that the air was not saturated to the extent indicated by the thermometer. In order to obtain steadier operating conditions the pipe arrangement was changed and saturated steam used for the gas plant in place of superheated.

The introduction of highly saturated and comparatively cool air into the producer results in cooling the fuel bed below a good working temperature. To prevent this a regenerator is provided wherein the temperature of air and steam mixture is increased to about 220 deg. cent. before it enters the producers, the necessary

Fig. 5 shows a diagrammatic view of a plant on the Lymn system. The air enters at the lower part of the No. 3 air washer, called the air saturator. The upper part of No. 3 is divided off by a diaphragm, the only connection between the two being through a water seal. The water which is made hot by contact with the gas in the upper part of the vessel passes through this seal into the air saturator and there meets the gas coming from the bottom of the vessel. The additional steam is blown into the air main between the air saturator and the regenerator (referred to in the figure as superheater), which consists of a nest of concentric cylinders so arranged that the hot gases from the producer and the saturated air pass in countercurrent. From the regenerator the hot gas is passed through a dust trap before it enters a vertical dust washer No. 1, in which the remaining dust is removed by water. From the top of the dust washer the gases pass down to the bottom of washer No. 2. In their upward flow through this washer they are brought into intimate contact with a solution of sulphate of ammonia containing a slight excess of sulphuric acid which absorbs ammonia from the gas. In the design of the Lymn washers no obstructions in the shape of packing boards

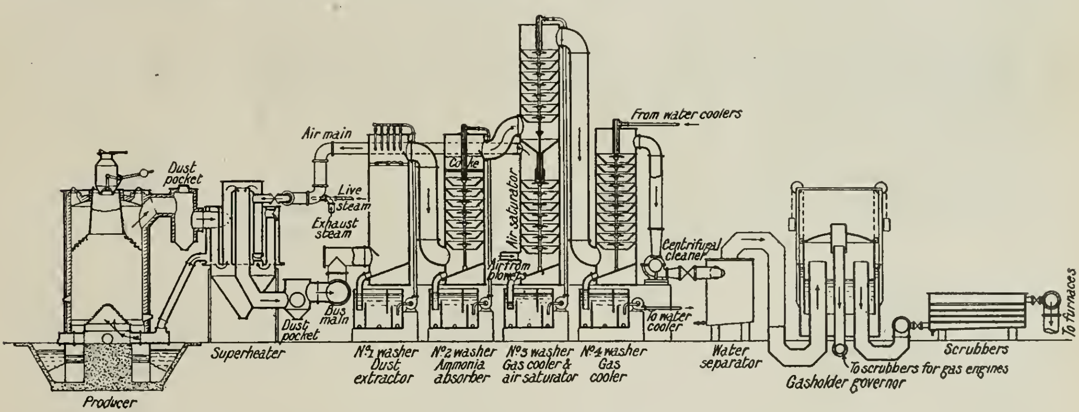

Fig. 5 Lymn Gas Plant, Sectional Diagram

or tiles and no moving parts are employed. The apparatus consists simply of several vertical cylindrical chambers, No. 1 of which is simply fitted with water jets at the top which fill the vessel with spray through which the gas passes in an upward direction and is thereby washed. Nos. 2, 3 and 4 contain a series of truncated cones axially placed in the center of the apparatus; a vertical shaft carries a number of fixed disks opposed to these cones. The water entering at the top is distributed on the topmost disk from which it flows in a film or sheet on to the surrounding cone, thence it falls on to the next disk and so on to the bottom of the washer. The gas passes upward, countercurrentwise, through the sheets of falling water. By this means the gas and the washing liquids are brought into intimate contact, with a minimum expenditure of energy.

In this instance the ammonia absorber was built of steel and the usual lead lining dispensed with. No particular corrosion was observed.

The gas, after leaving the final cooler No. 4, is passed through two Jenkins centrifugal gas cleaners and then through a water separator of the cyclone type, from which it goes into the gasholder, governor which is so arranged that in the event of the gas failing, the supply to the gas engines is cut off before that to the furnaces. This prevents any suction caused by the engine coming on the furnaces which might lead to an explosion should the gas come again suddenly. Gas intended for use in the engines is passed also through sawdust scrubbers to extract the last traces of tar. This proved to be necessary as the centrifugal-fan cleaners do not make the gas sufficiently clean for use even in furnaces, which in this instance are supplied through comparatively small pipes (down to $^3/_4$ in. pipes, the presence of small amounts of tar could not be detrimental.

As regards the power units, multi-cylinder horizontal Otto engines of about 500 b.hp. were selected, each gas engine being fitted with an exhaust boiler, the exhaust being connected to the boiler with a by-pass.

The original article contains extensive data as to the costs and operating results which would be of only minor interest in view of the fact that only British coals were used.

Careful inspection was maintained with respect to the possible corrosion of steel vessels, which in this case were not lead-lined. Practically no corrosion was observed which might have possibly been the result of the composition of the coal. The author's experience would lead one to believe that little corrosion takes place with mild steel unless the metal is also either subject to erosive action or is under stress.

In general, and as far as English conditions are considered, the author believes that low-grade fuel must be better utilized in the future than in the past. While not all coal will be either gasified or coked, there is every probability of much more coal undergoing one of these processes in the future than is the case at present. To what extent sulphate of ammonia recovery from fuel will pay will depend not only on the nitrogen content of the fuel and its price (together with cost of recovery, including capital charges), but also on the selling price of the sulphate, and this may be greatly affected by some of the processes of nitrogen fixation that have been so largely developed during the war. This last consideration is likely to have an important bearing on the adoption of a process for recovering ammonia from coal.

It may be of significant import that the writer claims the shortened week with only one operating shift as a most disturbing element in connection with power generation. The load factor is the most important element in cheap power and a high load factor is impossible with a short working week and only one shift working in the 24 hr. as this deprives the central station of the diversity factor which might make up for the short working hours employed by the consumers. (*The Journal of The Institution of Electrical Engineers*, vol. 58, no. 292, June 1920, pp. 417–430 4 figs., *d*)

REFRIGERATION

Ice Tank of New Design, C. Wilkie. Description of ice-freezing tanks installed in the Finney Avenue Plant of the Merchants' Ice and Coal Company, St. Louis, Mo.

During the season of 1919 it was decided to increase the capacity of the ice-freezing tanks in the plant, which could be done either by building a new tank or extending the old tanks. The latter

was much the cheaper plan but would make an excessively long tank, calling for a coil 1500 ft. long, provided the coil ran the full length of the tank.

The design finally resorted to called for a tank 114 ft. long, holding 856 cans freezing 400-lb. blocks. The general layout is shown in Figs. 6 and 7. In the first place, there is an expansion header made of 5-in. pipe and provided with nipples to receive the two connections from each double coil. The header lies in the bottom of the tank and fits the two bottom pipes of each double coil, which gives an even ammonia feed for each coil as the head must be half full of liquid before any of the coils can receive any of it.

The whole tank is arranged so that direct-expansion coils are in one end and flooded coils with the horizontal accumulator at the other end. In the direct-expansion end of the tank the coils are double, that is, two coils in one; in the flooded end of the tank triple or three-in-one coils are used, each 220 ft. long. The liquid ammonia for the flooded end passes through the direct-expansion coils, then through the 7-in. line to the accumulator, thence by gravity feed into the bottom of the flooded coils, the gas passing from the coils back into the side of the accumulator above the liquid fuel (Fig. 6).

Agitation is produced by a single propeller designed on the theory that higher efficiency can be secured with a large unit than with very small ones. The propeller is 36 in. in diameter and has three steel blades. It has a blade-tip speed of 16 ft. per sec. and is located in the center of the tank. It produces 7 in. of agitation, or one inch to seven cans.

In the original article tables are given showing the performance

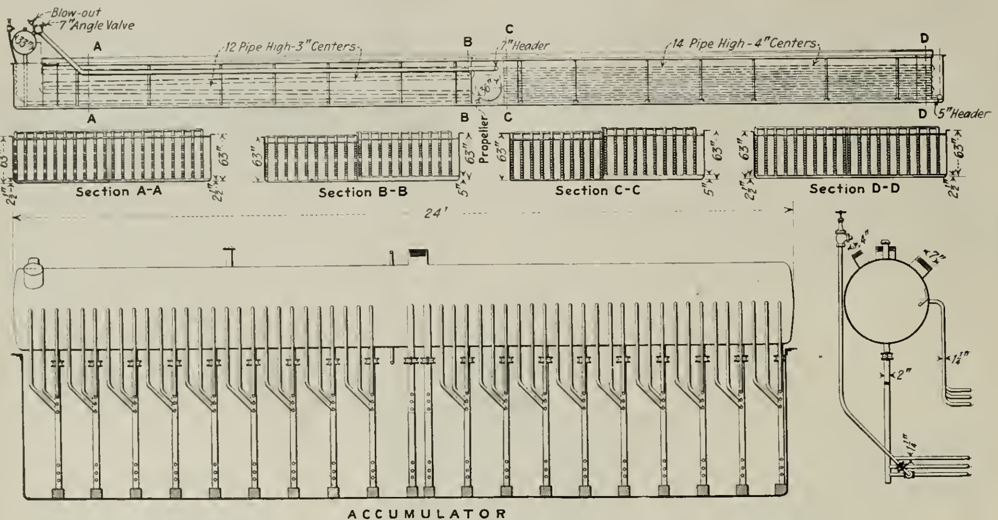

Fig. 6 General Layout of Ice Tank and Connections to Horizontal Accumulator

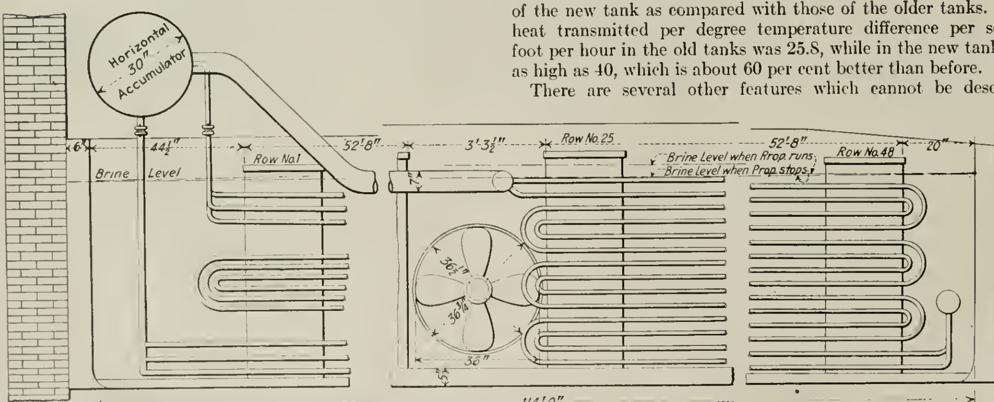

Fig. 7 Connection of Flooded Coils to Accumulator in Ice Tank

of the new tank as compared with those of the older tanks. The heat transmitted per degree temperature difference per square foot per hour in the old tanks was 25.8, while in the new tank it is as high as 40, which is about 60 per cent better than before.

There are several other features which cannot be described here for lack of space, such as the use of a special floor design, higher cans, means for holding cans vertical, and interesting hoisting and handling appliances. (*Power*, vol. 52, no. 21, Nov. 23, 1920, pp. 823–826, 8 figs., *d*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquires for further information in connection with articles reported in the Survey.

A Department Conducted by the Research Committee of the A.S.M.E.

A Research Information Bureau

THE National Research Council has established the Research Information Service as a general clearing house and informational bureau for scientific and industrial research. This "Service" on request supplies information concerning research problems, progress, laboratories, equipment, methods, publications, personnel, funds, etc.

Ordinarily inquiries are answered without charge. When this is impossible because of unusual difficulty in securing information, the inquirer is notified and supplied with an estimate of cost.

Much of the information assembled by this bureau is published promptly in the "Bulletin" or the "Reprint and Circular Series" of the National Research Council, but the purpose is to maintain complete up-to-date files in the general office of the Council. Announcement will be made from time to time of special informational files which have been prepared.

Requests for information should be addressed, Research Information Service, 1701 Massachusetts Ave., Washington, D. C.

Research Résumé of the Month

A—Research Results

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a résumé of research results with formulas or curves where such may be readily given, and to report results of non-extensive researches which in the opinion of the investigators do not warrant a paper.

Apparatus and Instruments A1–21. COMPARISON OF ELECTRICAL INSTRUMENTS. The Bureau of Standards has recently coöperated in the comparison of the standards of the various laboratories of a large electrical manufacturing company. The instruments used for measuring current, voltage and power were carried from one laboratory to another and to the Bureau of Standards. The instruments were carefully checked against the working standards of each laboratory and showed a close agreement between the apparatus used in the various plants. The test also indicated that the different types of instruments tested maintain their accuracy under varying conditions of transportation. Address Bureau of Standards, Washington, D. C., S. W. Stratton, Director.

Cement and Other Building Materials A1–21. POPPING OF LIME PLASTER. An eight-page article is to appear in the *Journal of the American Ceramic Society* on the Popping of Lime Plaster, by Warren E. Emley and Cecil H. Bacon. The work was done at the request of Committee C-7 of the American Society for Testing Materials. Seventy-two specimens were made in the original series of experiments to determine the effect of underburned or overburned lime, the method of slaking, the quality of the sand and the presence of certain suspicious impurities. It was shown that the chlorides of sodium and magnesium, while they do not cause popping, cause serious discoloration. Another series of experiments showed that impure hydrate soaked overnight with water developed the usual buff color, but when soaked in an airtight container the color was green. This accidental discovery led to the suspicion of ferrous iron, which was confirmed. A third series of tests confirmed the fact that iron in the metallic, ferrous or ferric condition was quickly changed into the ferric condition, with consequent expansion and popping. The iron from the coal ash is apt to enter the lime in the methods usually employed in operating kilns. Other compounds from coal ash may cause trouble as compounds formed from lime and silica or lime and alumina will hydrate slowly when exposed to water and will expand as they hydrate. It is impossible to identify these compounds by means of analytical chemistry, and being in a colloidal state identification by microscope is difficult. Experiments were made by picking the centers out of pops and analyzing these chemically and microscopically.

The following conclusions are drawn:

1 The popping of a lime plaster is caused by the presence of grains of a material which hydrates slowly and expands as it hydrates.

2 This material may be a compound of calcium with silica, alumina, or iron, or it may be an incompletely oxidized salt of iron.

3 Such compounds may be introduced as impurities in the limestone, as ash from fuel, or as impurities in the sand.

4 When such impurities are uniformly distributed throughout the limestone, they will not cause trouble, even when the lime is overburned, if two precautions are observed: the hydrate should be screened through a No. 48 sieve and should be soaked overnight before using.

5 When the impurities occur along bedding planes on the stone, or as balls of clay adhering to the stone, or are introduced as ash from the fuel, they can be identified by the formation of a dark vitreous crust on the surface of the lime. All such lime should be discarded as unfit for plastering.

6 The sand should contain not more than 1 per cent of the chlorides of sodium and magnesium. Common clay, leaf mold, and similar impurities, do not cause popping. Ferrous carbonate and magnetite are apt to cause trouble if they occur in particles coarser than 48 mesh.

7 Referring only to these impurities which commonly occur in lime, it may be stated that those particles which are large enough to stay on a No. 30 screen will be almost certain to cause noticeable popping. Those which pass a No. 30 and are retained on a No. 48 screen may or may not be troublesome. These which pass a No. 48 screen will not cause noticeable popping, if the lime is soaked overnight before use.

8 Production of lime which will not pop may be assured by following these three precautions: (*a*) Reject all lumps of lime which are encrusted with vitreous material. (*b*) Screen all hydrate through a No. 48 sieve. (*c*) Soak all lime putty overnight before using it as a plaster.

9 Popping can be caused by impurities in the brown coat as well as in the finish coat. The above precautions should therefore be applied to both mason's hydrate and finishing hydrate.

10 The method of testing for popping now in use is fundamentally sound and gives satisfactory results. It is believed, however, that a requirement for fineness would be of greater value as a part of standard specifications for lime.

Address Bureau of Standards, Washington, D. C., S. W. Stratton, Director.

Glass and Ceramics A1–21. CERAMIC PUBLICATIONS. The following publications dealing with ceramics have recently appeared:

1 The Rate of Vitrification of Porcelain Molded under Different Conditions, by R. F. Sherwood, in the October number of the *Journal of the American Ceramic Society.*

2 The Post-War Status of the Ceramic Industry, by A. V. Bleininger, *Chemical and Metallurgical Engineering*, Sept. 29, 1920.

3 Enamels for Sheet Iron and Steel, by Prof. J. B. Shaw, Technologic Paper 165 of the Bureau of Standards.

Address Bureau of Standards, Washington, D. C., S. W. Stratton, Director.

Metallurgy and Metallography A1–21. BEARING METALS. Experimental work on the compressive strength and hardness of white-metal bearing alloys at temperatures up to 100 deg. cent. has been completed and a paper has been prepared entitled Some Properties of White Bearing Alloys at Elevated Temperatures. The apparatus is described for determining the yield point and ultimate strength of white-metal bearing alloys. A new design of heating apparatus is described for determining the Brinell hardness of such metal under varying temperatures. The results of the compression test and the Brinell hardness are given for five typical white bearing-metal alloys, three tin-base alloys, one lead-base alloy, and one intermediate alloy. These tests show that the tin-base alloys maintain their properties better at elevated temperatures than those containing lead. Results indicate that up to 3 per cent the lead in a high-grade babbitt does not affect the yield point or ultimate strength at 25 deg. cent. or 75 deg. cent. The yield point of the tin-base alloy is not affected by heating for six weeks at about 100 deg. cent. The yield point of the lead-base alloy is lowered by heating for only two weeks at this temperature. Address Bureau of Standards, Washington, D. C., S. W. Stratton, Director.

Metallurgy and Metallography A2–21. MAGNETIC PROPERTIES OF EUTECTOID STEEL. A simple carbon steel of eutectoid composition has been examined to find the effect of the rate of cooling on the magnetic properties and other properties of an annealed eutectoid carbon steel. A paper describing this investigation has been prepared. It was found that the magnetic properties are considerably influenced by variations in the rate of cooling from above the critical range and the corresponding variations are produced in the microstructure. There was an agreement between the values of the coercive force and the scleroscope hardness. Address S. W. Stratton, Director, Bureau of Standards, Washington, D. C.

Mining, General A1–21. ASBESTOS. Report Serial No. 2179, by Oliver Bowles, gives the usability of asbestos from South Africa. The material is found in Rhodesia, the Union of South Africa, Transvaal, Cape and Natal. Bureau of Mines, Washington, D. C. Address F. G. Cottrell, Director.

Optics A1–21. Ultra-Violet Rays. The effect of ultra-violet rays from arc-welding outfits on the human eye has proven very serious. Conjunctivitis is produced unless heavy lenses made up of alternate layers of red or blue glass or orange glass of sufficient thickness are used. When eyes are injured by these ultra-violet rays, treatment should be given under the care of a physician. The usual treatment is to use ice packs for 15 minutes to an hour three to four times a day, to irrigate the eye with a salt solution of one teaspoonful to a quart of sterile water or saturated solution of boric acid several times daily. With pus discharge a few drops of 25 per cent solution of argyrol should be used in the eye three times to six times a day. The patient should be confined in a darkened room. Pain may be so severe as to require the administration of morphine. Report by Dr. C. R. Kindall, Surgeon, Bureau of Mines. Address Bureau of Mines, Washington, D. C., F. G. Cottrell, Director.

Petroleum, Asphalt and Wood Products A1–21. Evaporation Losses from Crude Oil. Evaporation Losses from Crude Oil during Piping and Storage on Oil Leases is the subject of a report, Serial No. 2169, by A. R. Elliott. The results show that the evaporation depends on temperature and amount of disturbance to which the oil is subject. Open tanks will lose more oil on a cool, windy day than on a hot, still day. A gastight metal roof is better than one made of timber. The atmosphere above the oil in a tank is saturated with oil vapors. Under sun heat a temperature sufficient to distill the higher fractions from the oil is obtained. To maintain a low temperature a lagged or shedded tank should be used. A water-sprinkled tank painted white was proven to be most effective. This was followed by a water-sprinkled tank painted black, a glossy-white-painted tank, a water-topped tank, a black tank and an oil-stained, loose-wooded roof tank. The evaporation of gasoline from the crude oil amounted to from 5 to 25 per cent. Bureau of Mines, Washington, D. C. Address F. G. Cottrell, Director.

Railway Rolling Stock and Accessories B1–21. Thermal Stress in Steel Car Wheels. An investigation to determine the stresses in steel car wheels similar to that recently completed on chilled-iron wheels has recently been begun and tests on six wheels have been completed during the month of October. Address Bureau of Standards, Washington, D. C., S. W. Stratton, Director.

B—Research in Progress

The purpose of this section of Engineering Research is to bring together those who are working on the same problem for coöperation or conference, to prevent unnecessary duplication of work and to inform the profession of the investigators who are engaged upon research problems. The addresses of those investigators are given for the purpose of correspondence.

Agricultural Equipment and Engineering B1–21. Wastes. The recovery of valuable by-products from agricultural wastes in California is being investigated by the Beckman & Linden Engineering Corporation. Address J. W. Beckman, President, Beckman & Linden Engineering Corporation, Atlas Building, San Francisco, Cal.

Apparatus and Instruments B1–21. Bourdon Tubes. An investigation of the characteristics with a study of hysteresis effects of bourdon tubes, using an optical lever system for the exact determination of displacements under varying conditions. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Automobile Vehicles and Equipment B1–21. Wear of Automobile Parts. Work for the Motor Transport Corps has been undertaken by weighing a number of bearings and gears on a sensitive balance, after which these are to be placed on cars in service. After a certain length of time these parts will be weighed. Address S. W. Stratton, Director, Bureau of Standards, Washington, D. C.

Cement and Other Building Materials B1–21. Terra Cotta Investigation. The thermal expansion of seven different glazes and ten underslips is being determined from rods recently made. The therma expansion of clay specimens has been determined. The transverse strength is being investigated to determine the difference between pressed and cast terra cotta. The results on the transverse strength show that the glazed side does not have as great a tensile strength as the unglazed side of the terra cotta. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Chemistry, Inorganic B1–21. Magnesia and Carbon Black. Researches on the electrolytic production of magnesium and on the manufacture of carbon black are under way at the laboratories of the Beckman & Linden Engineering Corporation. Address J. W. Beckman, President, Atlas Building, San Francisco, Cal.

Electrochemistry B1–21. Lead Storage Battery. A lead storage battery built on a new principle is being investigated by the Beckman & Linden Corporation. Address J. W. Beckman, President, Atlas Building, San Francisco, Cal.

Paints, Varnishes and Resins B1–21. Fireproof Paint. The Glenn L. Martin Company is at work on tests of fireproof paint in connection with aircraft. Address L. C. Milburn, Assistant Chief Engineer, Glenn L. Martin Company, Cleveland, O.

C—Research Problems

The purpose of this section of Engineering Research is to bring together persons who desire coöperation in research work or to bring together those who have problems and no equipment with those who are equipped to carry on research. It is hoped that those desiring coöperation or aid will state problems for publication in this section.

Mechanics C1–21. Strength of Tubings. Data are required on torsional stresses induced in light-wall steel tubes from 1 in. to $2^1/_2$ in. O.D. and of Nos. 14 to 22 B.W.G. wall thickness. The stress determined by the formula $S = Pac/J$ is desired. Pa is the turning moment, c the distance from the neutral axis to the outside fiber and J is the polar moment of inertia. The curve in Fig. 1 shows the results acquired thus far. Address L. C. Milburn, Assistant Chief Engineer, The Glenn L. Martin Company, Cleveland, Ohio.

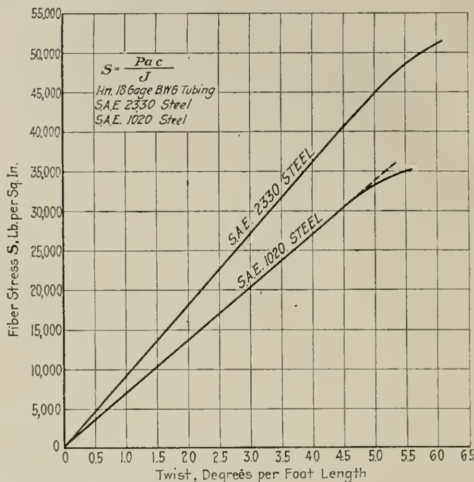

Fig. 1 Relation between Twist and Fiber Stress in 1-In. No. 18 B. W. G. Steel Tubing

D—Research Equipment

The purpose of this section of Engineering Research is to give in concise form notes regarding the equipment of laboratories for mutual information and for the purpose of informing the profession of the equipment in various laboratories so that persons desiring special investigations may know where such work may be done.

Beckman & Linden Engineering Corporation D1–21. See *Beckman & Linden Engineering Corporation E1–21.*

Glenn L. Martin Company, Cleveland, Ohio, D1–21. The laboratory of this company consists of the usual chemical and physical departments. The Materials Testing Department includes one 50,000-lb. Olsen tension machine, one Erichsen sheet-metal testing machine, one pendulum-type combined testing and shock-testing machine, one rib-testing machine. Address L. C. Milburn, Assistant Chief Engineer, Glenn L. Martin Company, Cleveland, Ohio.

Metal & Thermit Corporation D1–21. The Research Laboratory of the Metal & Thermit Corporation is equipped with various types and sizes of furnaces, including reverberatory furnsces, smelting furnaces and muffles. Equipment for leaching, grinding of laboratory samples and for quantities used in manufacturing. The research equipment is divided into three classes according to size. The smallest is used in the laboratory and the largest in separate buildings devoted to research work. Address Mr. J. H. Deppeler, Chief Engineer, Thermit Dept., Metal & Thermit Corporation, 120 Broadway, New York.

E—Research Personnel

The purpose of this section of Engineering Research is to give notes of a personal nature regarding the personnel of various laboratories, methods of procedure for commercial work or notes regarding the conduct of various laboratories.

Beckman & Linden Engineering Corporation E1–21. The laboratory has worked out successfully the separation of salts from natural brines and the production of various strontium and barium compounds from local ores. It has devised an efficient, cheap way of concentrating vinegar to a high percentage of acetic acid and hss suggested economical utilization of various waste products of the rice industry. The laboratory is at work on the electrolytic production of magnetism, on a lead storage battery built on a new principle, on the manufacture of carbon black and on the recovery of valuable by-products from agricultural wastes in California.

voltages. Semi-commercial units are installed for extracting and distilling processes. Address J. W. Beckman, President, Beckman & Linden Engineering Corporation, Atlas Building, San Francisco, Cal.

Metal & Thermit Corporation E1–21. The research staff of the Metal & Thermit Corporation, 120 Broadway, New York, consists of about ten men, including the following:

Dr. E. A. Beck, from the Technical Universities of Munich and Aix-la-Chapelle. Dr. Beck worked on iron, steel, lead, silver, copper and zinc. In 1908–1909 he worked with the Roechling Iron and Steel Works, using the electric furnace. In 1910 he worked for the American Smelting and Refining Company and the American Vanadium Company. Since 1911 he has worked with the Metal & Thermit Corporation.

Mr. S Lubowsky (B.S. and Ch.E.), Carnegie Institute of Technology 1913, Ch.E. in 1917. Formerly Chief Chemist, Reduction Works, Crucible Steel Company of America.

Mr. L. C. Mazzola, B.Sc. Cooper Union, 1917. Worked with the Dexola Chemical Company and the Wright-Martin Aircraft Corporation.

F—Bibliographies

The purpose of this section of Engineering Research is to inform bibliography is not extensive, this is done at the expense of the Society. For bibliographies of a general nature the Society is prepared to make extensive bibliographies at the expense of the Society on the approval of the Research Committee. These bibliographies are on file in the offices of the Society and are to be loaned on request. The bibliographies are prepared by the staff of the Library of the United Engineering Society which is probably the largest Engineering Library in this country.

Mechanics F1–21 Fatigue of Metals. See *Properties of Engineering Materials F1–21.*

Petroleum, Asphalt and Wood Products F1–21. Recent articles on petroleum and allied substances prepared monthly by the Bureau of Mines. Address F. G. Cottrell, Director, Bureau of Mines, Washington, D. C.

Properties of Engineering Materials F1–21. Fatigue of Metals. The Joint Committee on the Investigation of the Fatigue of Materials under the direction of Prof. H. F. Moore has prepared a 16-page bibliography of books, monographs and articles dealing with the fatigue of metals and with related phenomena. Address Prof. H. F. Moore, University of Illinois, Urbana, Ill., or A.S.M.E., 29 West 39th St., New York.

CORRESPONDENCE

Contributions to the Correspondence Department of Mechanical Engineering are solicited. Contributions particularly welcomed are discussions of papers published in this Journal, brief articles of current interest to mechanical engineers, or suggestions from members of The American Society of Mechanical Engineers as to a better conduct of A.S.M.E. affairs.

Readers Requested to Send Suggestions

To the Editor:

In my lectures on the principles of management, students are required to do coördinate reading from books written by prominent engineers and business men. This part of the course is proving to be of great value, but in order to make it as effective as possible I would like the help and suggestions of engineers as to the best books for this purpose.

The problem is one of selecting the volumes which will inspire the student to strive for high ideals in engineering and in the management of industrial affairs. My present list is made up from my own experience, but I am sure that many helpful suggestions might be received from practicing engineers who employ engineering graduates. I would be very glad to have suggestions from the readers of Mechanical Engineering.

Bruce W. Benedict.

University of Illinois, Urbana, Ill.

DeLamater Ericsson Tablet Committee Report

To The Editor:

In your October issue you printed a statement regarding the DeLamater Ericsson Commemoration held during the last annual meeting of the A.S.M.E. and the movement since then to erect memorial bronze tablets on the sites of four buildings in this city with which the lives and work of Mr. DeLamater and Captain Ericsson were associated.

As it was largely through the courtesy and assistance of the A.S.M.E., of which Captain Ericsson was a member, that this meeting and movement took place, the Committee feel that it would be proper to report in the columns of its publication the status of the subscriptions which have been made to them so far.

For the Commemoration Meeting each of the following societies subscribed $50.00:

American Scandinavian Alliance of Greater New York
American Scandinavian Foundation
American Society of Mechanical Engineers
American Society of Refrigerating Engineers
American Society of Swedish Engineers
Associated Veterans of the DeLamater Iron Works
Engineers' Club of New York
John Ericsson Memorial Committee (by Mr. John Aspegren, Chairman)
New York Historical Society
Society of Naval Architects and Marine Engineers
Union League Club.

Total Subscriptions	$550.00
Total Expenses	375.00
Balance	$175.00

The A.S.M.E. also furnished the auditorium, lantern and ushers, and the American Scenic and Historic Preservation Society, through its secretary, Dr. E. H. Hall, gave valuable assistance in arranging for the meeting and is printing an account of it, with excerpts from the addresses, in its report to the state legislature. Reprints of this report will be furnished to the subscribers to the meeting and to the Tablet Fund, which latter to date comprises individual members of the following societies and individuals:

Amaranthus Lodge, Independent Order of Odd Fellows	$25.00
American Scandinavian Foundation	10.00
American Scenic and Historic Preservation Society	25.00
American Society of Mechanical Engineers	99.00
American Society of Refrigerating Engineers	30.00
American Society of Swedish Engineers	250.00
Associated Veterans of the DeLamater Iron Works	256.00
Bredablick Lodge, Free and Accepted Masons	250.00
Capt. John Ericsson Memorial Society of Swedish Engineers	130.00
General Society of Mechanics and Tradesmen	323.04
John Ericsson Memorial Committee	75.00
Past District Deputy Grand Masters' Association of Greater N. Y.	10.00
United Swedish Societies of N. Y.	250.00
DeLamater family	700.00
Thomas F. Rowland	500.00
Ogden Mills	250.00
Wm. H. Todd	100.00
Stevenson Taylor	50.00
Brought forward balance of Commemoration Fund	175.00
Total Subscriptions (to date)	$3508.04
Total Expenses (to date)	$ 105.00
Balance	$3303.04

It is hoped that subscriptions from American societies will exceed or at least equal those of the Swedish societies and that there will be besides many patriotic and public-spirited individuals who realize and appreciate the valuable services which Mr. DeLamater and Captain Ericsson rendered to this country and will help to raise

the amount of the fund to $5000, which is what is needed to make and erect the tablets which the Committee have in hand.

The Committee has in hand the development of a motion-picture scenario of the life of Captain Ericsson, which was full of highly dramatic occurrences. This will be of great educational benefit to the public in advance of the dedication of the John Ericsson Memorial in Washington, D. C., on the 60th anniversary of the battle of the *Merrimac* and the *Monitor*, March 9, 1922.

Names of individual subscriptions will be supplied later.

H. F. J. Porter, *Chairman*,
DeLamater Ericsson Tablet Committee.

25 W. 39th St., New York City,
December 1, 1920.

Eliminating Monotony from Work

To The Editor:

At the meeting of the Society held on November 5, a very important principle was emphasized by Mr. Gompers when he stated that the efficiency of human life must take precedence of the efficiency of human production, and it was of the highest significance that Mr. Dickson, presumably viewing the situation from the opposite end of the industrial scale, in effect endorsed the statement of Mr. Gompers.

This statement admits the principle that the man is greater than either the dollar or the machine, and its acceptance by such representative men as Mr. Gompers and Mr. Dickson amounts in a sense to an official indorsement on behalf of all parties interested in the adjustment of industrial relations.

It will doubtless be readily admitted as a theoretical proposition that the man is more than the dollar or the machine, but actually to design our machines and processes with a view, firstly, to their effect upon the operator, and secondly, to their productive efficiency, means a radical departure from our present methods of procedure; and yet it would appear that the time has come when we must at least make some serious effort in this direction if we are to avoid the rocks which lie ahead.

The situation presents to the engineer a problem the solution of which must call into play his highest qualities, both social and professional, but at the same time it opens to him a field of usefulness which far transcends the mere production of physical wealth, and places him in a position of leadership in the upward progress of humanity.

It is most desirable that in dealing with this matter we should conserve, as far as possible, all that is best in our present system, not applying revolutionary methods, but guiding development along sound evolutionary lines.

One of the most productively efficient, but at the same time most humanly destructive, factors in our present system is monotony of operation, and it seemed to be the consensus of opinion that the evils of this could not be overcome without destroying the method. The productive advantages of this method however, are so great, both to the community at large and to the producers, that every effort should be made to ameliorate the evils without too great a sacrifice of efficiency, and the writer is hopeful that much may be accomplished in this direction.

The question which presents itself is: Are the evils of a monotonous process entirely inherent in the monotony, or can they to some extent be eliminated? To be more specific, is the distress chiefly caused by the contemplation of a monotonously recurrent process, or by what we may term a monotonously received fatigue shock?

The validity of this question will be apparent if we consider such an operation as hand knitting. Those who are expert in this work carry it on in such an automatic manner that they can engage in conversation or other form of mental activity without detriment to the work, and yet it is such as these who find knitting to be a pleasurable occupation; but if we look into the matter closely we shall find that the work is generally carried out under the most comfortable conditions and with a minumum of fatigue.

There is an old superstition which is dying, it is true, but dying hard, that a workman earns his wages in exchange for his fatigue. Let us forget this superstition and admit that fatigue is an evil and the enemy of efficiency; would it not then be possible to redesign some of our more monotonous processes so that they may be carried out under the most comfortable conditions and with a minimum of fatigue shock?

The writer does not expect that all the evils of monotonous operations can be eradicated, but as it is obvious that most of them have been designed without due consideration of the above factors, he is very hopeful that a full investigation of the subject may lead to valuable results. James O. G. Gibbons.

East Orange, N. J.

Specialized Training in College

[An article on The Training of Engineering Students in Industrial Management by Prof. W. B. Benedict of the University of Illinois, published in the September issue of Mechanical Engineering, p. 492, brought forth a letter of discussion by W. D. Ennis, New York, N. Y., which appeared in the November issue of Mechanical Engineering, p. 640. The following is a further discussion of this subject, presented in a letter to Mr. Ennis and here published by permission.—Editor.]

I have read your letter in the November number of Mechanical Engineering with much interest, because, having spent the major part of sixteen years in technical teaching, and eight in marine engineering, about four years at sea, and the remainder in designing and estimating, I feel that I have combined engineering and commercial experience in sufficient quantities to enable me to get a good idea of just how much of what a man gets in college is useful to him afterward. I might add that during all my teaching years I had from three to four months every summer as vacation, and that I devoted nearly all these periods to practical work in various engineering plants.

Now there is nothing at all brilliant about myself; I am today "rotten" at pure calculus; much of theoretical thermodynamics; the higher and more mathematical parts of alternating currents; and all the more abstruse parts of naval architecture. Consequently, I feel that it is quite fair, in such things, to judge others by myself. The net result of this judgment is that we cannot afford in the four years that is all most boys can spend in college, to specialize them too much. In other words, we cannot turn out managers, superintendents, production engineers, time- and motion-study experts, transportation men, automotive men, internal-combustion experts, etc. I took my own course in mechanical engineering under the stern but beloved administration of the late Dean Joseph F. Klein; and as an undergraduate I often criticized Lehigh because there were no shops there, and no "practical work" such as other colleges had. To be sure, we had our "shop visit" courses, with the free run of the Bethlehem Steel Co., the Bethlehem Foundry & Machine Co. and other local industries, besides the Lehigh Valley Shops and the Ingersoll-Sergeant Works at Easton, and occasional trips to Niagara Falls and other centers of industry or power development; but *we did no work with our hands*, with the exception of a little in the college laboratories. But we did have the principles, the mathematics and the mechanics of it all most thoroughly drilled into us, and I think we went out able to tackle, *at the bottom*, any branch whatever of mechanical engineering. I had grown up, myself, in the mining and manufacturing city of Wilkes-Barre, Pa., and had spent much of my spare time around the shops and mines; and when I entered college, I was quite "fingerwise," as Gilbreth says.

And when I left college, and through the kindness of the late James S. Doran was allowed to go away to sea on the old *Pennsylvania* of the Red Star Line, I found that even the small store of practical experience I had already acquired was of small use. Even jobs that seemed similar were done in a different way. I learned how to "take leads;" how to work up a set of indicator cards without a planimeter; that Whitworth nuts will run down on a Sellers stud, but Sellers nuts won't run down on a Whitworth stud; and that taking the "lost motion" out of a 24-in. crankpin was an entirely different job from taking it out of a 3-in. one. During the years I spent at sea I was transferred around from ship to ship as all engineers are, and served under several different chief engineers; and two of these men were masters of

Shipbuilding Corporation on Shooter's Island, and Mr. Coxe is once more my chief, as he is now vice-president and general manager of the Pusey & Jones Company. They were the only "post-graduate professors" I ever had, and none could have been better. ....And after some years at sea I went into a marine drafting room and began to get another line of instruction and experience.

I found, for instance, that it was possible to get out all the principal dimensions of a triple-expansion engine in a few hours, and that my college bugaboo, thermodynamics, could be entirely dispensed with, barring a few figures and tables. And I remembered that Mr. Hunter had once told me at sea that all engineering consisted of "decimal fractions, common-sense and experience." Another time, when I was overhauling an especially mean set of metallic packing, Mr. Coxe had come along the grating and said, "All that trouble comes from too much 'white shirt' in the drafting room."...And through all this I wondered whether going to college had done me one bit of good....But I see now, and have seen for a good many years, that it had done me all the good in the world: for one thing, it taught me not to be afraid of anything that came up. Had I learned how to take leads or chip oil grooves and keyways in college, it would have been at the expense of some of those general principles that had been hammered into me.

Since I have been with my present employers my work has been principally marine estimating. We have here a pretty good system, and we are making it better right along. I could teach this system or method in a college, but I should want students who were at least seniors, and good ones at that; and I should want at least a year to do it, with lectures, recitations, practicum and quizzes. And when I had a boy as well taught as possible, do you think any shipyard would give him a *responsible* job at a good salary? Not in twenty years! He'd have to work up to it from the drafting room, the shops or the yard. So many boys seem to have a horror of the drafting room. They place where they can make an immediate use of what they have learned in college. If they go into the shop, the youngest apprentice boy can "show them up," and their ignorance of shop practice is apt to make the so-called practical men about the plant think that, because they don't know much about the way things are done in the shop, they don't know anything. Nobody seems to think that an architect ought to be a skillful bricklayer, yet lots of shop men think that if a man can't run a milling machine or line up an engine, he can't do anything in the plant. Not that a good knowledge of shop practice is not a tremendous asset to any mechanical engineer: in fact, it is a *sine qua non* of really good design. And any chap with proper ambition can get all he needs by putting in his summer vacations at it while he is still in college. And after he goes to work, if he starts in the drafting room, he can learn a great deal by making friends with the various foremen, and submitting preliminary designs to them for their criticism. This is especially helpful, not only in fostering a spirit of coöperation, but in enabling a draftsman to design to suit his own plant's shop equipment; for often what is the best way to design for one shop is the wrong way to design for a shop with a different outfit of machine tools. I learned this by costly experience, and pass it along for what it is worth.

Probably you have been able to guess that my principal object in this letter, though not very precisely stated, is: Don't introduce *any* highly specialized course into a *college*. Leave them to trade and industrial schools and to post-graduate courses How many boys entering college *know* what they want to do? Not one in fifty. So give them the great General Principles, and let them hew out a niche for themselves, where they will fit, after they get out. I once heard the late Eckley Coxe say, "If your four years in college have taught you nothing but that you are unfitted for the profession you set out to study, they have not been wasted."

Wilmington, Del. W. S. Ayars.

WORK OF THE A.S.M.E. BOILER CODE COMMITTEE

The Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York, N. Y.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in Mechanical Engineering.

Below are given the interpretations of the Committee in Cases Nos. 318 to 321 inclusive, as formulated at the meeting of October 14, 1920, and approved by the Council. In accordance with the Committee's practice, the names of inquirers have been omitted.

Case No. 318

(In the hands of the Committee.)

Case No. 319

Inquiry: Is it allowable, under the requirements of Par. 308 of the Boiler Code, to connect to a boiler to be operated at a pressure exceeding 15 lb. and not to exceed 100 lb. for the return of condensation to a heating system, a 4-in. return connection, this same return connection being used as a blow-off, but the blow-off connection therefrom being reduced, however, to $2^1/_2$ in. pipe size or less?

Reply: It is the opinion of the Committee that such a connection for return of condensation will not be in accordance with the requirements of Par. 308 of the Code. It will be necessary to use an independent connection for the return.

Case No. 320

Inquiry: Will it meet the requirements of Par. 303 of the Boiler Code where a non-return angle valve is mounted directly on the steam outlet nozzle of a boiler, and to the outlet of this valve there is bolted a gate valve, forming the two stop valves required, to provide the ample free-blow drain between the two valves by a $1^1/_2$-in. pipe tap in the side of the non-return angle valve just above the seat, in order to avoid the necessary of placing a fitting between the two valves?

Reply: It is the opinion of the Committee that such a construction will fully meet the requirements of Par. 303.

Case No. 321

Inquiry: Is a boiler of the porcupine type where stub tubes are screwed in the furnace sheet subject to the requirements of Par. 250 of the Boiler Code, or is the screwed connection of such stub tubes permissible?

Reply: Par. 250 refers specifically to fire-tube boilers and is therefore not applicable to a boiler of the porcupine type in which the tubes are operated under conditions similar to those of the water-tube type of boiler. Par. 251 refers to tubes which are expanded into the tube sheets and does not apply to tubes with screwed ends. It is the opinion of the Committee that the pipes or tubes should meet the requirements recommended by the Committee in the reply for Case No. 296—that special redrawn pipe, not to exceed $1^1/_2$-in. standard pipe size made from lap-welded iron of puddled stock and tested to 1000 lb. hydraulic pressure, may be used for a working pressure not to exceed 200 lb. per sq. in., provided the wall thickness is at least 50 per cent greater than the wall thickness required by the Code for tubes of water-tube boilers. The minimum number of threads should conform with the values given in Table 8 of the Code. The closed ends of the stub tubes may be welded by the forging process.

The Engineer's Work at Hog Island

Carl C. Thomas

THE great shipyard at Hog Island, built by the American International Shipbuilding Corporation for the Emergency Fleet Corporation of the United States Shipping Board, has served successfully the purpose for which it was built and will soon be closed. Many of the members of this and of the other engineering societies were instrumental in carrying forward this undertaking, and the building of the plant and ships is one of the greatest examples of engineering and industrial coöperation. Not only were the executives and engineering forces drawn from many branches of the engineering profession, but the material for the ships and their equipment was supplied by more than 3500 different companies located in widely separated sections of the country. To the able and enthusiastic efforts of these organizations is due in large measure the marked success with which the program was carried out. The closest coördination was necessary to bring together materials and equipment in proper sequence to fit into a carefully planned construction program of such magnitude.

The Hog Island Yard is just completing the last of its contract for 122 steel vessels of the highest rating in Lloyd's and the American Bureau of Shipping Registries. Most of these ships have been in service for many months—and the *Quistconck*, the first to be completed, has steamed upward of eighty thousand miles. A recent examination showed here to be in first-class condition in every respect. Similar records have been made by many of the other Hog Island ships and all have given entirely satisfactory performance. The *Liberty Glo* was blown in two by a mine in the North Sea in December, 1918. Both ends floated ashore on a Dutch island some miles away, saving both crew and cargo, with the exception that two men who left the ship in a small boat died from exposure, and the cargo in the one ruptured hold was of course lost. The ship was put together again in Holland and has been in satisfactory service ever since under her original rating. At least six cases are on record in which Hog Island ships have rescued disabled vessels and towed them safely to harbor. The twelve 8000-ton troop-carrying vessels built in addition to one hundred and ten 7800-ton cargo ships, are to be used principally by the Army Transport Service, their interior arrangements having been radically changed from the original design to suit the revised army requirements. The last of the troopships are now about to go into service and the great yard, which was taken over by the United States Shipping Board according to the original arrangement with the American International Shipbuilding Corporation, is to be disposed of by the Shipping Board.

Hog Island is the largest shipyard in the world. The 50 ways occupy a waterfront over a mile in length, the wet basins and outfitting piers about three-quarters of a mile, and the storage yards at the two ends bring the total length to about two and a half miles. The width of the yard is about three-quarters of a mile. There are 84 miles of standard-gage track serving the storage yards, warehouses, ways and wet basins. Each of the seven outfitting piers is 1000 ft. long and accommodates four ships, so that 28 ships can be berthed at one time. During the war, in the period of greatest activity at the yard, fully 36,000 employees were constantly at work. The shipyards and engineering establishments of the country as a whole were in urgent need of all the labor that could be made available and it was an enormous task to maintain the great force of men required by such an undertaking as that at Hog Island. The work of building the yard was started in September 1917, and by the early part of February the 900 acres of swamp land had been so far drained, graded and built upon that the first keel could be laid at that time. Wherever buildings, tracks or ways were to be constructed the ground required that piles should be driven. An enormous amount of dredging was necessary along the river front and all of this work was done in spite of the unprecedented severity of the weather in the winter of 1917–1918. The building of adequate roads and providing of transportation facilities between Philadelphia and the shipyard, a distance of about nine miles, was in itself a great task; and in addition housing accommodations were provided for several thousand employees at the Island.

The designing of the ships and their equipment and the ordering of material proceeded contemporaneously with the designing and building of the shipyard, and material for the ships was rushed to the Island with the greatest possible speed. The work of storing the enormous quantities of material required for so large a number of ships and of arranging for delivery in the sequence necessary for systematic progress in construction, required the services of a large and well-organized storage department. Perhaps an even greater task devolved upon the purchasing department because of the fact that everything going into the ships was made and purchased and inspected in distant places. This required a very large force of inspectors and expeditors as well as an elaborate system for tracing the vast shipments of material.

In the old-line shipyards the material constituting the ships, from hull steel to and including equipment, is largely worked up and made at the yard. In the case of Hog Island everything had to be made away from the shipyard and delivered in a condition so true to the drawings that the parts would fit together satisfactorily. This involved much more detailed design work than would otherwise have been necessary and an unusual amount of care upon the part of the inspection force. This was especially true because the greater part of the material was made by firms who had never before done marine or shipbuilding work. For example, rudders were made at steel works in Kansas City, Minneapolis, Pittsburgh and Cleveland; anchor windlasses in Chattanooga; winches in Minneapolis and Ashtabula; capstans in Denver; and hull steel was worked up, sheared and punched to templet in some forty different fabricating shops in as many localities.

The close coöperation required by these conditions has undoubtedly had the effect of uniting the engineers of this country and bringing them into closer working contact. It has also given great cause for a feeling of encouragement as to the ability of our industries to rise to an emergency and serve the country with energy and enthusiasm in time of need. The difficult conditions

It is greatly to be regretted that misinformation regarding this great project was spread throughout this and other countries. In common with other undertakings for which Government agencies were ultimately responsible, Hog Island suffered from malicious attacks from political groups. Expensive and time-consuming investigations were set on foot by these agencies which greatly delayed shipbuilding and which, far from discovering any of the dishonesty or incompetence charged, only served to show conclusively that the work was being done energetically and effectively; and in spite of great difficulties, attaining a speed of production and excellence of output which could not be brought about by any but an exceedingly high-grade and well-organized body of engineering executives.

Hog Island now stands in the eyes of the country as one of the striking examples of what American engineers can do. It is one of the very few instances in which a war venture has been so conceived, constructed and operated as to be able to continue producing a successful product in times of peace.

Elaborate investigations conducted after the yard was completed and in operation showed that it had cost far less than the sum which would have been necessary to reproduce it at the time of the investigations.

This country may well be proud of its great engineering firms which have carried through with fidelity enormous undertakings for the benefit and convenience of mankind; and of the fact that one of these firms organized and brought to successful issue the great undertaking at Hog Island, in response to the emergency call for ships. Carl C. Thomas.

Measuring the Two-Hundred Millionth Part of an Inch

Our knowledge of engineering phenomena is limited by our ability to measure them. The difference between engineering knowledge and guess lies in the fact that the former is based upon data obtained from actual measurements, while the latter presupposes and assumes things which may or may not be so.

With this in mind it is easy to see why any refinement in our methods of measurement is likely to bring about a material increase in our knowledge of engineering phenomena. This has been well illustrated in the great realm opened up by the ultra-microscope. In the field of measurement of lengths the micrometer has been of incalculable value for many years. Of late, however, new methods of measurement based on the employment of light waves have extended the precision achieved by micrometers to within the region of one-millionth of an inch, and now comes the ultra-micrometer of Professor Whiddington of Leeds University, by means of which measurements to within the scarcely credible limit of one two-hundred millionth of an inch can be carried out with apparently great precision. This novel method is based on certain electrical phenomena which may be in general described as follows:

If a current be sent through a circuit containing an inductance coil and a condenser, the circuit will have what is known as a natural frequency, that is, a certain frequency of alternations depending on the respective values of the inductance and capacity involved.

If another circuit with an inductance and capacity be magnetically linked with the first circuit and a telephone be inserted in the first circuit, a sound will be heard in this telephone whenever the frequencies in the two circuits do not exactly coincide. The volume of the sound and hence its audibility depend, however, on the current flowing and the difference between the frequencies in the two circuits, and it is obvious that in order to make the device very sensitive it is necessary to make the telephone sensitive to extremely small variations, which can be done only by having both the current and the difference in frequencies very small.

On the other hand, as stated, the frequency in the primary circuit varied by varying the distance between the condenser plates, which is the distance that has to be measured, or is proportional to the distance measured.

Here again it is obvious that if the distance between the condenser plates changes by a magnitude of the order of a small fraction of a millionth part of an inch, the circuit must be extremely sensitive to record it. An ordinary oscillating circuit does not have this great sensitiveness, but by using the so-called "thermionic valve" developed primarily for wireless telephone and telegraph work the current in the primary circuit may be magnified many times before it is sent into the telephone without, however, materially disturbing either the frequency or the shape of the wave. In a thermionic valve the initial current, which may be and usually is extremely minute, establishes a flow of ions between two elements enclosed in a vacuum. This flow varies in frequency, direction and intensity exactly as does the initial current. There is also a secondary circuit established which is linked with the primary circuit in such a manner that one of its terminals is constituted by one of the elements of the valve between which the ionic flow takes place, while the other is located between the two elements. It is now obvious that when there is no current in the primary valve circuit, there is no flow of ions between its two terminals. Hence there is a vacuum between the terminals of the secondary circuit and no current can flow therein. As soon, however, as a current is established in the primary circuit, ions are projected from one of its terminals to the other over the terminal of the secondary circuit located between them. As a result a sort of bridge is established between the terminals of the secondary circuit, permitting the current in that circuit to flow. Every interruption in the primary circuit is accompanied by a corresponding interruption in the secondary circuit, and the strength of the secondary current varies as the resistance in the gap between its terminals in the valve, which, in its turn, varies as the number of ions in that gap, or as the strength of the primary current.

Now a variation of one two-hundredth of one-millionth part of an inch between the plates of the condenser would be far below the range of sensitiveness of an ordinary telephone, but it is sufficient to affect the sensitiveness of the thermionic valve and to change the flow of ions between its terminals, which, in turn, produces changes in the much larger current taken from an independent source and thus gives a sufficient current to affect the diaphragm of the telephone.

If the Whiddington ultra-micrometer can be developed to the practical stage so as to make its use possible in engineering laboratories (sufficient information is not yet available to show whether this has been done or not), its applications may prove to be both extensive and important. It has already been found that it permits measuring the deflection of a solid wooden table produced by the weight of a coin placed on its edge. There is certainly need of an apparatus capable of measuring the minute deflections produced by the application of small loads and stresses to members of large cross-section. For example, it would be of interest to see how large bridges are affected by small loads. Many years ago it was stated that it would be possible to wreck the Brooklyn Bridge by means of a violin so played that the vibrations set up would always be in unison with the oscillations of the bridge. Whether this can be done or not is not very important; but whether such structures undergo minute oscillations or not may prove to be a matter of considerable value.

Another problem that might be investigated by means of the new apparatus is the law of deflection of springs under small loads, a law of which we are entirely ignorant. The question of expansion of metals under very small changes of temperature is also one that might be considerably cleared up by our ability to carry out measurements in the region of fractions of a millionth part of an inch.

The foregoing are only a few of the problems in whose solution the ultra-micrometer might be of service. And to repeat again what was said in the opening paragraph, our knowledge of engineering phenomena is limited by our ability to measure them.

Government Reorganization and a National Department of Public Works

At the last meeting of Engineering Council held in Chicago, M. O. Leighton, Washington representative of the Council, presented a report dealing with the activities of the National Department of Public Works Association.[1] With Congress now in session, interest in a National Department of Public Works has naturally revived, and it is therefore timely to make a rather complete report on the progress of the movement. The following has accordingly been abstracted from Mr. Leighton's report:

Two outstanding facts which were not anticipated when the public works movement took shape in April 1919, are first, that the engineers of the country in good faith started something which they do not now seem inclined to finish, and second, that the scope of the movement and its ramifications extend beyond all limits written or spoken of at the time.

The Movement for Government Reorganization

The fundamental arguments for a Department of Public Works apply with equal force to the entire Government organization. There has grown in a short space of time a country-wide movement for Government reorganization. The National Education Association, the Women Voters' League and the Federation of Women's Clubs, are supporting a proposed Department of Education. The American Public Health Association and other organizations in the realm of sanitation and preventative medicine are supporting a Department of Health. Certain welfare organizations are advocating a Department of Public Welfare; there is also a movement for a Department of Aeronautics; and an old movement for a Department of Mines still exists. The National Budget Committee, having practically completed its labors in behalf of a budget system of Federal Finance, is actively turning its attention to the entire field of Federal reorganization. The National Budget Committee, the Public Works Department Association, and the National Education Association are participating in the activities of what is known as the National Committee for Governmental Economy, the purpose of which is to make and report upon a complete study for governmental reorganization. The report is practically completed.

In all of these organizations, with possibly one exception, the creation of a Department of Public Works is an accepted doctrine. Opposition exists in some of the organizations to the purposes of some others, but all unite in favoring a public works program, and the most favorable feature of this is the general agreement that the Department of Public Works should be created not through the creation of an additional Cabinet office but by a readjustment of the agencies already existing. It is the other new departments, therefore, that will have to carry the heavy legislative burden of overcoming the opposition to enlargement of the Cabinet.

The Amalgamation of Reorganization Efforts

Early in October there was a meeting in New York City, attended by Messrs. John T. Pratt, head of the National Budget Committee; Herbert Hoover; Henry L. Stimson, former Secretary of War; Paul Warburg; Major C. T. Chenery, and the writer, at which matters of Government reorganization were discussed, and particularly the need for and the possibility of amalgamating all reorganization efforts under a commonly accepted and supported program. It was brought out that if the many organizations conduct campaigns separately, each for its own particular project, the confusion created in Congress will probably result in no legislation. It was therefore decided to call a meeting of delegates from the several organizations advocating reform in the Government departments, to organize a Federal Reorganization Council, which would be the common body through which an accepted program would be carried forward.

The aforesaid meeting of such delegates was held in New York on October 14, at which time the nearly completed report of the National Committee on Governmental Economy was presented. That program provided for a general rearrangement of Government activities along functional lines, including the creation of a Department of Public Works by a reorganization of the present Interior Department, and an additional department to be called the Department of Education and Health, into which would be drawn such welfare activities as war risk insurance, vocation and rehabilitation, pensions, etc. The meeting for final organization will take place about November 15. The prospective field of such a council is not limited to the mere reorganization of Federal activities. It should become the authoritative unofficial body to engage in the work which will eventually lead to a distinct separation of the political features of our Government system from the conduct of departmental business.

The obvious result of all this is that a Department of Public Works, if created, will not be an achievement of engineers and architects solely, but of men and women of many professions and avocations. Such credit as will come to the engineers will be merely that of starting a good thing, unless the members of the profession revive their interest and resume a leading part in the campaign. If such a revival does not take place the cream of achievement will be skimmed by the members of other professions.

To summarize as to the prospects for a Department of Public Works. It is the writer's belief that the principle is thoroughly settled in the minds of the public and of a majority of the members of Congress. The important question remaining is the kind of a department that we shall have. This involves a discussion of the matter of engineering control of Government operations. Shall it be civil or military?

Civil or Military Control of Government Operations

It is easy enough for the thousands of engineers of the United States to assert that engineering work of the Government shall be under civilian control, but it is quite another thing to establish that control. The engineers of the country must decide speedily whether it be their desire to have military engineers in control of the public works of the nation, for if they do not bestir themselves and take a sustained and active interest in this matter they will suddenly find that the die has been cast. When Government reorganization takes place the provisions made for engineering control will crystallize and will not become mobile again for at least a generation. It all comes down to a question of what the civilian engineers want and what they will work for. They are strong enough numerically and powerful enough in influence to guide the decision if they choose to do so, but they must not entertain the notion that their adversary is asleep.

[1] The National Public Works Department Association is a league composed of individuals, associations and of national, state and local societies, having an aggregate membership of over 100,000 business men, engineers, architects, constructors, manufacturers, chemists, geologists and economists. Its purpose is to organize under one department the many and varied public-works functions of the Federal Government. M. O. Leighton is chairman of the Association, and C. T. Chenery, secretary. The Association's headquarters are in the McLachlen Bldg., 10th and G St., Washington, D. C.

Federal Power Commission

Perhaps the most important item to engineers in the 1921 estimates of Government expenditures was a relatively small one calling for a total appropriation of $482,065, for the requirements of the Federal Power Commission. Of this $100,000, it is estimated, is required to reimburse executive departments for investigations requested by the Commission; $137,000 for general expense for the authorized work of the Commission and $240,000 for salaries. All of these estimates appear to be conservative, in fact, as small amounts as will permit of effective operation of the Commission under the requirements of the law.

Before these estimates can be acted on for appropriation by Congress, however, it is necessary under the law to so amend the existing power act as to permit the Commission to spend the money so appropriated. If the law is not amended giving the Commission this additional power any appropriation bill carrying the item above referred to is subject to a point of order because regular appropriation bills cannot carry new legislation. It was evidently the intent of the original Federal power bill to give the Commission authority to hire and pay its personnel and to expend funds which were appropriated for it, but under a ruling of the controller of the Treasury these funds did not become available.

Since this whole appropriation will affect practically every phase of the engineering field, it is probable that engineers and engineering organizations as such should use their efforts to obtain, first, adequate legislation that will enable the Commission to properly expend this money, and second, an appropriation that will permit of proper execution of the law. The need of this legislation and its proper administration is best shown by the fact that 115 applications for permits or licenses for power development have been filed with the Commission in less than six months with an aggregate horsepower of over eight million.

A.S.M.E. Student Prize Award

The A.S.M.E. Student Prize for 1920, it was announced at the Business Meeting of the Society held during the Annual Meeting, has been awarded to Howard G. Allen, a graduate of Cornell University, for his paper on Wire Stitching Through Paper. This prize, consisting of an engraved certificate signed by the President and Secretary of the Society, and twenty-five dollars, is given to the member of a Student Branch who submits the best paper adjudged from the standpoints of applicability (practical or theoretical), value as a contribution to mechanical engineering literature, completeness, originality of matter and conciseness. This prize is provided for by a fund of $1000 established through the generosity of a member of the Society as an incentive to the young engineer to undertake original work and is in line with the practice of many other societies. A similar fund provides an award for the best paper submitted by a Junior Member; there were, however, no contestants for the latter award this year.

ber, 1858, in Boston, Mass. He was educated in the Boston schools and attended the Massachusetts Institute of Technology from which he received his S.B. degree in 1879.

Upon graduation he became connected with the C. B. & Q. Railroad, leaving that road several years later to become general foreman of the car shops for the Eastern Railroad Company. From 1885 to 1888 he was general foreman of the car department for the same company. In 1888 he became connected with the Boston & Maine Railroad as assistant master car builder and the following year took a position in the same capacity with the L.S. & M.S. Railroad. Three years later he became general master car builder for that company and was with them until 1899 when he became superintendent of motive power and rolling stock of the New York Central Railroad. He held this position until 1903 when he resigned to open consulting offices in New York City in which field of work he was engaged until the time of his death.

During the War, however, Mr. Waitt, who held the commission of Major, gave up his practice temporarily to organize one of the largest purchasing branches of the Ordnance Department in New York and Hartford. His death was due to overwork in this undertaking into which he entered so whole-heartedly.

During his connection with the New York Central he was made a member of the Electric Traction Commission which planned the electrification of the road from New York to Harmon. He also assisted in designing one of the best locomotives in use at that time, among them the engines of the series 1400 and 2900. He was asso-

Arthur M. Waitt

ciated after his retirement from the New York Central with Colonel William J. Wilgus in the appraising of the rolling stock of the Lehigh Valley Railroad. He was an enthusiastic supporter of the automatic train control and a director of the Sprague Safety Control & Signal Corporation.

In 1893 Mr. Waitt was elected president of the Central Railroad Club of Buffalo and in 1895 president of the Western Railroad Club of Chicago. As one of the officers of the Lake Shore & Michigan Southern Railroad, he was a participant in the famous high-speed run of October 24, 1895, from Chicago to Buffalo; a run which, it is believed, has never been equalled. The test started at 3:29 a.m. in Chicago and ended at 11:30 a.m. in Buffalo, a total distance of 510.1 miles, done in eight hours, one minute and seven seconds.

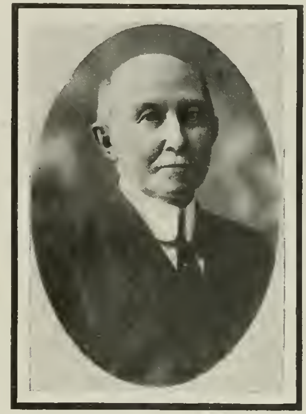
In 1901 Mr. Waitt was elected president of the American Railway Master Mechanics' Association. In 1916 he became a member of the Connecticut Assembly and it was he who wrote the automobile laws now in force in that state.

Mr. Waitt was also a member of the Connecticut Chamber of

He became a member of The American Society of Mechanical Engineers in 1893 and held the office of vice-president from 1900 to 1902.

Edward W. Thomas

Edward W. Thomas, former president of the National Association of Cotton Manufacturers and for the last eleven years agent of the Boott Mills, Lowell, Mass., died of heart disease at his residence in that city on November 15, 1920. Mr. Thomas was generally regarded as one of the ablest cotton manufacturers



Edward W. Thomas

in the country, having held responsible positions with mills both in the North and in the South. His eminent fairness in all matters of mill routine which came to him for discussion had won the confidence of the employees and this quality, combined with an unfailing courtesy even to the most humble operative, was a potent factor in the successful development of the large plant which he directed for the past eleven years.

He was born on February 22, 1858, in Lowell, Mass. He spent all of his business life in cotton manufacturing, starting as a draftsman with the old Lowell Machine Shop and leaving that concern to enter the employ of the American Thread Company at their plant in Willamantic, Conn. In 1882 he became superintendent of the Tremont & Suffolk Mills, Lowell, and four years later became agent for the corporation.

During this period he was particularly active in the affairs of the National Association of Cotton Manufacturers, serving as vice-president from 1892 to 1894 and as president in 1894 and 1895.

About 1900 Mr. Thomas went south to become general manager of the Cooleemee (N. C.) Cotton Mills, and in 1904 he assumed the more responsible position of general manager of the Olympia and Granby Cotton Mills, Columbia, S. C. Three years later he became general manager of all the plants of the Consolidated Cotton Duck Company, Baltimore, Md. In 1909 Mr. Thomas returned to Lowell as agent for the Boott Mills, which position he held at the time of his death.

Mr. Thomas was a member of both the National and American Associations of Cotton Manufacturers, the Boston Textile Club, the Yorick Club of Lowell and the Lowell Historical Society, of which latter he was vice-president. He had long been prominent in masonry and was a Knight Templar and a thirty-second degree mason.

He became a member of The American Society of Mechanical Engineers in 1880, attending the organization meeting at Stevens Institute of Technology on April 7, 1880. He served as secretary of the sub-committee on Textiles from 1912 to 1914.

SIDE CUTTING OF THREAD-MILLING HOBS

(*Continued from page 11*)

fore, if the correction is taken as the tangent of the profile at the pitch line of the thread, the angle C' will remain unchanged. The formulæ for determining this angle are as follows:

Let C = $\frac{1}{2}$ included angle of thread
C' = $\frac{1}{2}$ included angle of corrected hob
H = helix angle of thread at pitch line

Then

$$\tan H = \frac{1}{\pi N \times \text{pitch diam. of thread}}$$

and

$$\tan^2 C' = \tan^2 C + \tan^2 H$$

It is evident from the above that if the form of the cutting edge of a hob of a certain diameter be corrected to cut a thread of a certain diameter and pitch, a variation in the diameter of the hob of, say, 25 per cent will have but little effect on the form of the thread produced on the work.

In order to determine the effect of varying the diameter of the work, the following tabulation was made for a hob 2.000 in. in diameter with 5 Acme threads per inch:

Work diam. =	1.000 in.	2.000 in.	4.000 in.
x_2 =	0.003475	0.001161	0.000350
y_2 =	0.012344	0.004103	0.001512
$2C'$ =	30° 0′ 16″	29° 14′ 8″	29° 3′ 6″
$F - 2x_2$ =	0.0619	0.0666	0.0682
K =	0.000054	0.000012	0.000003

The above tabulation shows that the amount of side-cutting at the bottom of the thread (x_2) decreases as the diameter of the work increases. The height of the fillet at the bottom of the thread (y_2) decreases as the diameter of the work increases. In this case it decreases about four times as much as x_2. The included angle of the corrected hob decreases quite rapidly as the diameter of the work increases. The width of the point of the corrected hob increases about 0.006 in. as the diameter of the work is increased from 1 in. to 4 in. The dimension K in Fig. 5-B decreases as the diameter of the work increases. In this case the amount of error introduced by a straight-line correction in the hob is in the fifth and sixth decimal place and is negligible. It is evident, therefore, that a hob which is corrected for a certain diameter of work cannot be used on work which varies very much in diameter if accurate results are desired. The smaller the diameter of the work, the more this condition is accentuated. This is due in large measure to the rapid increase of the helix angle on smaller diameters. On work of large diameters, where the helix angle employed is very small, little or no correction is required on the hob.

RAILWAY TERMINALS AND TERMINAL YARDS

(*Continued from page 21*)

There is but one railway whose freight tracks reach Manhattan Island. All the other lines maintain the connection by lighters. One hundred years ago it was the Hudson River that furnished an outlet for the Erie Canal and carried New York to the first place among American cities, thus establishing its ever-increasing commercial supremacy. On the advent of railways they, one by one, except the Hudson River Railroad, located their terminals on the Jersey shore and lightered their traffic across the water. As their business developed they increased their facilities, and as the city grew they created new points of delivery, but always maintaining their separate and individual identities. The consequence is that every railway coming from the west maintains on the Jersey shore great yards occupying valuable space whence freights are transferred by floats to various points not only on the edge of Manhattan Island, which was New York when railway traffic originated, but to the greater parts of what is now New York, namely, Brooklyn, Long Island and the Bronx.

Is this necessary? If it is not necessary, is it the best and most economical arrangement? Should not the terminal facilities of the several roads be pooled, thus concentrating operation on the part of the railways? Instead of maintaining special delivery stations in New York, can there not be a combining there, with perhaps a further segregation into places for delivery according to commodities? If the principle of "store door" delivery be adopted there seems to be no necessity for water-front terminals in New York and water-front yards in Jersey. New yards with switching connections at both ends can be constructed with modern freight houses and unloading tracks equipped with labor-saving freight-handling machinery. These could be located in any convenient place, even on the wide expanse of the Jersey meadows. To them motor trucks with trailers carrying not part but full loads would transport merchandise between cars and points of origin or destination in any part of the Metropolitan District. In such a system would there not be economy in handling, time saved in trans-terminal shipments and a relief to street congestion through diminished number of trucks? The first two are for the immediate benefit of the railways and shippers, but the last is for the benefit solely of the city.

There is a fourth advantage in which the nation as a whole and the Metropolitan District would share jointly. Already New York's harbor terminal facilities are overtaxed and there is danger of surplus foreign traffic seeking against natural laws other and consequently less well-situated ports. The freeing of such a large area of water-front property now held for local freight purposes only would render available a site for the finest kind of ocean-steamship terminals. This property is most advantageously located for such purposes. It would have complete rail connection with all lines and could be physically improved with piers having ample storage facilities and cargo-handling machinery. The opportunity would be presented whereby the port of New York could be almost indefinitely extended and with advantages, vastly superior to those now existing or obtainable elsewhere.

The writer is aware that none of these questions are new. They have all been asked before, but the present moment is a fitting one to ask them all again when our transportation lines are entering upon new principles of operating economy, and when all men feel the need of general readjustment of business methods to meet the new world conditions.

A Correction

We are advised that the superheaters installed at the new Ford plant, a description of which was published in Mechanical Engineering for November, were designed, manufactured and installed by the Locomotive Superheater Company, of New York. Credit was inadvertently omitted from the article.

Index to Volume 42 of Mechanical Engineering

An index to Volume 42 of Mechanical Engineering is now in the course of preparation, which, it is expected, will be issued early in February. A copy of this index will be sent to each member of the Society or subscriber who sends in a written request therefor. In order that no more copies than are necessary to supply the demand may be printed, requests for copies should be received at headquarters not later than February 1.

1921 Year Book

On the recommendation of the Publication and Papers Committee and the Finance Committee, the Council has agreed to defer the publication of the A.S.M.E. 1921 Year Book until about October 1.

The 1920 Year Book was corrected on March 1, but on account of printing difficulties did not reach the membership until about July 1. In deferring the publication of the new book until October the interval between the two volumes will be only fifteen months.

The list of Council officers and Committees published in the front part of the volume will probably be issued about February 10. This will be printed in the usual page size and slipped into the 1920 book for the time being.

Standard Ton of Refrigeration Defined

A special committee of The American Society of Mechanical Engineers consisting of Messrs. Fred Matthews, Chairman, Henry Torrance, Jr., Secretary, Charles W. Berry, Peter Neff, John E. Starr, and Gardner T. Voorhees, the membership of which was endorsed by the American Society of Refrigerating Engineers, was recently appointed to fix a "Standard Tonnage Basis for Refrigeration." Its findings reported to The American Society of Mechanical Engineers at its Annual Meeting held on December 7–10 were as follows:

(1) A standard ton of refrigeration is 288,000 B.t.u.

(2) The standard commercial ton of refrigeration is at the rate of 200 B.t.u. per min.

(3) The standard rating of a refrigerating machine[1] using liquefiable vapor is the number of standard commercial tons of refrigeration it performs under adopted refrigerant pressures.[2]

[1] A refrigerating machine is the compressor cylinder of the compression refrigerating system, or the absorber, liquor pump and generator of the absorption refrigerating system.

[2] These pressures are measured outside and within 10 ft. of the refrigerating machine, distances which are measured along the inlet and outlet pipes, respectively; (a) the inlet pressure being that which corresponds to a saturation temperature of 5 deg. fahr. (−15 deg. cent.) and (b) the outlet pressure being that which corresponds to a saturation temperature of 86 deg. fahr. (30 deg. cent.).

The Committee and The American Society of Mechanical Engineers will welcome a full and free discussion of these three propositions. Communications should be addressed before February 15 to the Standards Department of The American Society of Mechanical Engineers, at 29 West 39th Street, New York City. As we go to press, we are informed that this report has been approved by the American Society of Refrigerating Engineers.

What is "Wrought Pipe?"

When the pipe maker takes a length of steel skelp and a length of wrought-iron skelp and forms them into pipe, he performs exactly the same operation on both materials, that is, he bends them into tubular shape and welds the edges. Quite correctly, therefore, the American Society for Testing Materials in their specifications use the word "welded" in conjunction with both wrought-iron and steel pipe made by the processes of welding.

Probably some thirty years ago, after the introduction of welded steel pipe, the term "wrought pipe" or "wrought steel pipe" was coined by steel-pipe manufacturers; this term gradually came into use by dealers and jobbers; thus steel pipe would be billed and listed as "wrought pipe." The average consumer of pipe, not acquainted with this trade name frequently labors under the impression that it means wrought-*iron* pipe. In fact, the names being so much alike, have led to the term "wrought-iron pipe" by the jobbers and contractors being interpreted as meaning steel pipe, defying architects' and engineers' specifications and resulting in endless confusion.

The manufacturers of wrought-iron pipe, actively aided by the American Institute of Architects, have therefore taken up with the supply associations the matter of clarifying these so-called trade names, suggesting instead names that would ultimately result in eliminating all confusion of puddled wrought iron with pipe made from soft steel. It was argued that trade names which conceal the truth are misleading, even to buyers who are supposed to be well informed, and that the substitution of the word "welded" for "wrought" would create a common term for both kinds of pipe impossible of misinterpretation. As a result the National Pipe and Supplies Association at their meeting held in New York on November 11, voted that the terms employed by the American Society for Testing Materials in differentiating between iron and steel pipe, viz.: (a) Welded Wrought-Iron Pipe, and (b) Welded Steel Pipe, should be accepted and adhered to by the distributors of both iron and steel pipe, this being in the interest of the manufacturers of the pipe, those who distribute it, and those who use it, each of these parties being entitled to know clearly and without doubt the make and quality of the pipe involved in the transaction.

This step should result in the term "welded pipe" being applied when *both* wrought iron and steel pipe are referred to, and that the latter two terms alone, namely, "wrought-iron pipe" on the one hand and "steel pipe" on the other hand, be used and interpreted respectively to mean exactly what these terms imply. Thus "wrought-iron pipe" will mean only pipe which is made from genuine puddled wrought iron, and "steel pipe" will be used exclusively to designate pipe made of soft bessemer or open-hearth steel.

American Engineering Standards Committee Recently Enlarged

The American Engineering Standards Committee has recently been enlarged by the representatives of four additional member-bodies. These bodies and names of their representatives are as follows:

(1) U. S. Department of Agriculture; T. H. MacDonald, Chief, Bureau of Public Roads

(2) U. S. Department of Interior; O. P. Hood, Chief Mechanical Engineer, Bureau of Mines

(3) Gas Group (consisting of American Gas Association; Compressed Gas Manufacturers' Association; International Acetylene Association); A. Cressy Morrison, Vice-President, Compressed Gas Manufacturers' Assn.

(4) American Electric Railway Association (official representative not yet designated).

There are now forty-seven members on the Committee, representing seventeen member-bodies, and twenty-four organizations as three of the member-bodies are groups of organizations.

The Committee recently held its annual meeting in New York and A. A. Stevenson, a representative of the American Society for Testing Materials, was reëlected chairman for 1921, and George C. Stone, a representative of the American Institute of Mining and Metallurgical Engineers, was reëlected Vice-Chairman. The following were also elected to represent the respective member-bodies on the Executive Committee:

Comfort A. Adams, American Institute of Electrical Engineers
Martin Schrieber, American Society of Civil Engineers
Fred E. Rogers, American Society of Mechanical Engineers
A. H. Moore, Electrical Manufacturers Council
Dana Pierce, Fire Protection Group
A. Cressy Morrison, Gas Group
N. A. Carle, National Electric Light Association
Albert W. Whitney, National Safety Council
Coker F. Clarkson, Society of Automotive Engineers
Thos. H. MacDonald, U. S. Department of Agriculture
E. B. Rosa, U. S. Department of Commerce
O. P. Hood, U. S. Department of Interior
Francis J. Cleary, U. S. Navy Department
J. H. Rice, U. S. War Department.

National Standardizing Body Organized in Austria

There has recently been formed in Austria a national engineering standardizing body. It is called the "Normenausschuss der Oesterreichischen Industrie" and is organized under the auspices of the "Hauptverband der Industrie Deutschoesterreichs." The Secretary is Dr. Jaro Tomaides.

This is the tenth national standardizing body to be formed, the others being in Belgium, Canada, France, Germany, Great Britain, Holland, Sweden, Switzerland, and the United States. Mechanical Engineering for September contained a brief description of the form of these organizations, all of which, with the exception of the British Engineering Standards Association, whose work dates from 1901, have been formed since the beginning of the European war.

The Recataloging of the Engineering Societies Library, New York

Work Begun in September, 1919—The Steps Involved and Difficulties Encountered—Results to be Gained and their Great Value to Engineers

By HARRISON W. CRAVER, DIRECTOR

THE Engineering Societies Library of today has for its ancestors four separate libraries which began at different periods, were developed in different ways and with varying ideals, and had not attained the same degrees of development when they were combined. The methods of classifying the books and of cataloging them in use in the separate libraries were so dissimilar that a revision of all this work was essential if members were to nse the collection conveniently, and with any assurance that all the material available had been found.

The Library Board therefore decided, early in 1919, to undertake the recataloging of all the material. As no nniform scheme for classifying the books was in use, much reclassification is also involved. A special corps of workers was assembled for the task and since the fall of 1919 the energies of the staff have been chiefly concentrated upon it.

As it is believed that the methods adopted will not only fix the practice of the Library for years to come, but may also become the standard for other engineering collections, every effort has been made to adopt methods that will both meet present needs and also provide for future developments, so far as these can be predicted. This has involved the sacrifice of speed, but as the work is intended to be permanent, basic soundness has been considered the prime quality.

At present, approximately one-fourth of the work is done. The recataloged material inclndes all the pnblications of the past four years, and those classes of the older material most in use; among others, the periodicals, and the geological material for many states. Work on the remaining material is proceeding class by class, the most important classes being treated first.

The following extracts from a report submitted in October by Miss Margaret Mann, chief cataloger, give detailed information on certain phases of the problem. They will, it is hoped, be of interest to many engineers and members of the A.S.M.E. as showing what has already been done, the difficulties to be overcome and the results anticipated when the work is finished.

During the year from September, 1919, to October, 1920, 23,204 books have been completely cataloged, and 31,679 volumes have been handled in order to catalog these 23,204. The 23,204 volumes represent 5000 titles. From these 5000 titles we have made available 10,301 subjects. To catalog 23,204 volumes, or 5000 titles, completely by author and subject, we have had to handle 31,679 volumes, which has necessitated the preparation and filing of 53,793 cards and the typing and filing of 840 sheets into loose-leaf binders. This has been accomplished with a staff averaging ten.

Steps Involved in Recataloging

The recataloging involves the following processes:

1 *Classification of the Book.* This means fitting the book into an accepted system of classification and getting it into its proper relation with all other books in the collection. Requires *expert* assistants.

2 *Compiling an Alphabetical Key or Index to This Classification.* This key now numbers 10,000 entries.

3 *Developing the Classification.* Making additions for the new subjects which are constantly coming up in engineering.

4 *Cataloging.* So recording the book that it may be reached from any angle—author, subject or title. This often involves the preparation of ten or more cards for each title and necessitates careful bibliographical research.

5 *Shelf Record of Books.* A record of every book as it stands on the shelves by number. Necessary (1) as an inventory of the library collection and (2) to avoid duplicating the individual symbol by which each book is known in a library.

6 *Record of Magazines and Transactions of Societies.* A loose-leaf record of every set in the library, showing not only the volumes on our shelves but also what volumes, indexes, etc., are needed to make our files complete. The compilation of this list has been slow work because of the condition of the sets. Many volumes are unbound, making it necessary to do very careful collating, while other volumes are incorrectly bound and incorrectly marked, making reference to them impossible. Many duplicates have necessarily been handled in the process of combining the several societies' collections.

7 *"Want" List of Magazines and Transactions of Societies.* This list shows at a glance what volumes are needed to complete our files. It can be sent to dealers for bids on missing numbers and volumes, and can also be printed in our own society journals and used as a means of calling the attention of members to our wants. Many incomplete sets might be filled through this channel. The Library has never before been able to take advantage of offers of duplicate volumes from other libraries or from individuals because no such list of our needs was available.

8 *Binding.* Every volume sent to the bindery must be collated, tied up and a record made of the author, title and volnme number, together with directions to the binder as to style and kind of binding. When the volumes are returned, these records must be checked.

9 *Preparation of Books for the Shelves.* Every book must bear a symbol which shall distinguish it from every other book in the collection, so that it may take its proper place on the shelves. This symbol is placed on the back of every book, and the societies' book plate is pasted into each volume before it is sent to the shelves.

10 *Shelving of the Books.*

11 *Filing of the New Catalog Cards and the Removal of the Old Records from the Old Catalogs.* The removal of old cards is an important but arduous task. To leave these cards in the catalog means that readers or assistants will look for books under the old numbers and so be misled. This is one of the difficulties of keeping both the old and the new going at one, and the same time.

Difficulties Encountered

The work has been necessarily slow this year because of the following difficulties:

1 *Difficulty of Keeping All Material Available While the Recataloging is in Process.* So long as the Library is kept open, every book must be available when needed. This often retards the work of the cataloger by requiring him to keep the books he is cataloging accessible to readers, when different methods would be more efficient for the cataloging process.

2 *The Necessity of Making Old Records Guide One to the New Records.* Constant references must be made to show what classes of books are in process, what have been recataloged, where they are located and to what extent completed.

3 *Inadequate Equipment*, especially shelving, book trucks, filing cabinets, etc.

4 *Distance of Records* from the catalog workman. The main catalog, which must be constantly consulted, is on the 13th floor, while the work room is on the 14th.

5 *Scattering of Material on Three Floors.* We have found it necessary in tracing a periodical set to inspect twenty different records or shelves before we were sure all material and information had been collected which bore on that special title.

6 *Necessity of Collating Unbound Material.* The collection is made much more difficult to handle because so little binding has been done. The tying and untying of hundreds of unbound volumes adds materially to the time required for recording these.

7 *Inability to Get Binding Done During the Current Year.* It has been difficult to get adequate work or service and the cost has been increased.

8 *Difficulty of Getting Good Trained Assistants.* The "after war" advance in library salaries has made it impossible for us to get the kind of assistants which such specialized work as this really requires. We were forced to take workers who were inexperienced in this line and train them, with the result that we have only been able to get efficient service during the latter half of the twelve months during which the work has been in progress. The training of the staff has often made it difficult for the chief recataloger to give adequate time to the solution of problems which necessarily arise in connection with any such piece of reorganization.

The possibilities for service are not limited to the Library; our service should be extended to those engineers who are groping for the best methods of indexing and classifying engineering literature. Many requests have already come for help along these lines, which opens up a field of work not only mnch needed but which must be developed if our influence, our methods and our material are to reach all members of the engineering field.

9 *Care of Duplicates.* In this consolidation of libraries the handling of duplicates form no small part of the work. An effort is constantly being made to dispose of our surplus stock. This means the listing, checking and packing of these books and considerable correspondence relative to their disposal.

The Results to be Gained by Recataloging

1 *Making the Resources of the Library Available.* By the recataloging, the varying methods of cataloging and classifying formerly used by the societies are being eliminated, bringing the collection together into a logical whole. Much of the material handled by the cataloging staff this year cannot be called recataloging, because many classes of books now in the Library have not, up to this time, been represented in the catalog. Such difficult work as the cataloging of the state and federal documents is quite new to this Library. Some of the most valuable material covering such subjects as Mining, Geology, Foreign Trade, Water Supply, Road Engineering, etc., is to be found in the reports and bulletins issued by state surveys, commissions and experiment stations.

now in process of making can be used and printed ...
arranged that one class such as Hydraulic Engineering is complete in itself and is not scattered under Pumps, Dams, Water Flow, etc. An alphabetical index takes care of Pumps, Dams and Water Flow, while the whole class of Hydraulic Engineering remains as a unit. Should a smaller class be needed, such as Dams, this will also be found to be a complete unit.

3 *Weak Spots in the Collection* will be revealed and records furnished for filling in the gaps. Until the books are combined under one classification it is quite impossible to see wherein the Library is weak.

4 *Establish a System of Classifying Engineering Literature* which can be applied not only to books but also to the indexing of periodicals.

5 *An Alphabetical Key* to the classification will thus be compiled, which, if published, will enable any engineer to index his own library, and his own periodicals, by the most approved international method at a minimum cost. This has never before been accomplished by any library or any individual and its completion will see a real contribution to engineering literature. It is an aid which engineers are seeking.

Book Notes

Industrial Relations Association of America. Procedings, Annual Convention, Chicago, 1920. Paper, 6 x 9 in., 592 pp., $5.

The papers presented at this conference, held in May 1920, are divided into two groups, one consisting of general problems and the other of those peculiar to specific industries. The collection covers a wide range of topics connected with the relations of workmen and employers.

Engineering Electricity. By Ralph G. Hudson. John Wiley & Sons., Inc., New York, 1920. Cloth, 9 × 12 in., 190 pp., illus., tables, $2.50.

This text represents the lectures given at the Massachusetts Institute of Technology to those technical students who are not specializing in electrical engineering. The course covers the general principles of electrical engineering and magnetism most frequently applied in engineering practice.

Financial Engineering. A Text for Consulting, Managing and Designing and Designing Engineers and for Students. By O. B. Goldman. John Wiley & Sons, Inc., New York, 1920. Cloth, 6 × 9 in., 271 pp., illus., tables, $3.50.

The author of this treatise has in mind the practicing engineer, interested in installing plants that will have the highest financial efficiency, although not necessarily the highest mechanical efficiency. The book is therefore an exposition of methods for determining the comparative value of the things which the engineer must use, and the financial efficiency of undertakings.

Elements of Engineering Thermodynamics. By James A. Moyer, James P. Calderwood and Andrey A. Potter. John Wiley & Sons, Inc., New York; Lond., Chapman & Hall, Ltd., 1920. 216 pp., illus., tables, folded chart, 6 × 9 in., cloth $2.50.

This treatise is an extension of a briefer work entitled Engineering Thermodynamics, by James A. Moyer and F. A. Calderwood. It is intended to bring out the fundamental principles of the subject, particularly for use in technical colleges where special courses on steam turbines, internal-combustion engines, refrigeration and other applications of thermodynamics can be given. Additions and changes have been made to the original material, to make the book better adapted to special requirements.

Fundamental Principles of Electric and Magnetic Circuits. By Fred Alan Fish. First edition. McGraw-Hill Book Co., New York, 1920. Cloth, 6 × 9 in., 194 pp., illus., $2.75.

This volume is intended as an introduction to the study of electric-power machinery and transmission. It discusses the principles that the author considers fundamental, is intended for undergraduate students, and therefore does not go deeply into the physical and mathematical theory of electricity, nor include all the possible variations in conditions which might affect the application of the principles as stated.

Fuel Oil in Industry. By Stephen O. Andros. The Shaw Publishing Company, Chicago, 1920. Cloth, 6 × 9 in., 214 pp., illus., tables, $3.75.

The volume opens with a discussion of the physical and chemical properties of fuel oil, the principles of its combustion, a comparison boiler furnaces and on types of burners. The remaining portion of the book describes the applications of fuel oil in steamships, locomotives, iron and steel manufacture, heat treating, central stations, the sugar, glass and ceramic industries, and in heating buildings. The treatment is concise and practical rather than theoretical.

Handbook for Heating and Ventilating Engineers. By James D. Hoffman, assisted by Benedict M. Raber. Fourth edition, McGraw-Hill Book Co., New York, 1920. Flexible cloth, 4 × 7 in., 478 pp., illus., tables, $4.50.

Supplement: A Course of Instruction for Technical Schools with Questions, Problems and References. To be used in connection with the Handbook for Heating and Ventilating Engineers—Hoffman; paper, 4 × 7 in., 51 pp.

This volume is intended to fill the need of those engaged in the design and installation of heating and ventilating apparatus for a pocket book covering the entire subject in simple form and containing the tables commonly used. The present edition has been entirely rewritten and reset, and considerably enlarged, to bring it into accord with present practice.

Industrial Housing. With Discussion of Accompanying Activities; Such as Town Planning, Street Systems, Development of Utility Services, and Related Engineering and Construction Features. By Morris Knowles. First edition. McGraw-Hill Book Co., Inc., New York, 1920. Cloth, 6 × 9 in., 408 pp., illus., tables, $5.

The author endeavors to develop the things which must be considered in order to provide not merely houses but homes, with all the attendant attributes of a living and livable town, and his book is the result of a realization that the preparation of a successful town plan and the development of a contented industrial community are dependent upon the action of many agencies and require the coördination of men of many professions. Although the work of an engineer, the book is not a treatise on technical practice, but is intended to represent the views of experts in architecture, town planning, landscape gardening, engineering, sanitation, public utilities, building, real estate, civics and business, for whom, together with city officials, the book is intended.

Tin, Sheet-Iron and Copper-Plate Worker. By Leroy J. Blinn. New enlarged edition. Henry Carey Baird & Co., Inc., New York, 1920. Cloth, 5 × 8 in., 334 pp., illus. tables, $3.

A revised edition of a well-known work on the working of sheet metal, containing rules for laying out work, recipes for solders, cements, and lacquers, as well as the tables and other data used by the mechanic.

The Ownership and Valuation of Mineral Property. Being an Elementary Treatise on the Nature of Mineral Interests and Royalties, and the Correct Method of Valuing such Property for the Purpose of Sale, Probate, and Rating and Taxation, together with a Statement of the Law relating to Rating and Taxation. By Sir R. A. S. Redmayne and Gilbert Stone. Longmans, Green and Co., New York, 1920. Cloth, 6 × 9 in., 256 pp., $4.50.

The primary object of this book is to assist the mining expert who desires to have available a statement of the interests involved and the mode of valuing those interests in the mining industry generally. The work consequently contains, in addition to chapters on royalties and valuation, a general explanation of the law relating to mining interests, way leaves and subsidence, and also the law relating to the rating and taxation of mineral properties.

The Practice of Lubrication. An Engineering Treatise on the Origin, Nature and Testing of Lubricants, their Selection, Application and Use. By T. C. Thomsen. First edition. McGraw-Hill Book Co., New York, 1920. Cloth, 6 × 9 in., 607 pp., illus., $6.

After a brief, practical description of commercial oils, fats and greases, the author describes the chemical and mechanical tests used and explains the laws of friction. Methods of lubrication are then described. The greater portion of the book is given to a discussion of the selection and use of lubricants for specific types of machinery, covering all classes of machines. Oil recovery, purification, storage and distribution, oils for cutting and for transformers are also discussed. The viewpoint throughout is that of the engineer rather than the chemist.

THE ENGINEERING INDEX

(Reg. U. S. Pat. Off.)

THE ENGINEERING INDEX presents each month, in conveniently classified form, items descriptive of the articles appearing in the current issues of the world's engineering and scientific press. At the end of the year the monthly installments are combined and published in book form, this annual volume having regularly appeared since 1906. In the preparation of the Index by the engineering staff of The American Society of Mechanical Engineers some 1200 technical publications received by the Engineering Societies Library (New York) are regularly reviewed, thus bringing the great resources of that library to the entire engineering profession.

Photostatic copies (white printing on a black background) of any of the articles listed in the Index may be obtained at a price of 25 cents per page, plus postage. A separate print is required for each page of the larger periodicals, but wherever possible two small or medium-sized pages will be photographed together on the same print. The bill will be mailed with the print. When ordering photostats identify the article by quoting from the Index item: (1) Title of article; (2) Name of periodical in which it appeared; (3) Volume, number, and date of publication of periodical; (4) Page numbers. Orders should be sent to the Engineering Societies Library, 29 West 39th Street, New York.

ACCIDENT PREVENTION

Foundries. Coöperative Methods for Preventing Foundry Accidents, R. A. Salisbury. Iron Age, vol. 106, no. 20, Nov. 11, 1920, pp. 1268–1269. Committee system of organization including employees is suggested. Paper read before Nat. Safety Council.

Organization for. Employees Rewarded for Self-Protection. Iron Age, vol. 106, no. 19, Nov. 4, 1920, pp. 1189–1191, 4 figs. Organization for accident prevention at plant of Joseph T. Ryerson & Son. One of features is offering prizes to employees with safety records.

ACCIDENTS

Building Construction. Keeping Track of Accidents, F. A. Davidson. Bul. Associated Gen. Contractors, vol. 11, no. 10, Oct. 1920, pp. 14–16, 2 figs. Systematic method for checking safety. Report adopted by Construction Section of National Safety Council.

Foundries. Dangers in Casting. Metal Industry (Lond.), vol. 17, no. 17, Oct. 22, 1920, pp. 323–325. Extracts from annual report of British Chief Inspector of Factories for 1919.

Railway Shops. Shop Accidents, J. A. McNally. Ry. Rev., vol. 67, no. 19, Nov. 6, 1920, pp. 715–716. Costs of accidents in railway shops. From records of Wabash Railroad.

Recording of. Standard Method of Recording Construction Accidents. Eng. News-Rec., vol. 85, no. 18, Oct. 28, 1920, pp. 845–847, 3 figs. Argument and instructions for compiling accident statistics formulated by Construction Section of National Safety Council.

ACCOUNTING

Amortization of War Facilities. The Amortization of War Facilities—II, Arnold F. Van Pelt. Indus. Management, vol. 60, no. 5, Nov. 1920, pp 345–351. Practical examples of tax relief through amortization.

ADSORPTION

Colloidal. Colloidal Adsorption, Arthur Mutscheller. Jl. Am. Chem. Soc., vol. 42, no. 11, Nov. 1920, pp. 2142–2160, 4 figs. Experimental study of migration velocity of anions as influenced by presence of reversible colloids, concentration of anions and cations as influenced by presence of reversible colloids, etc.

AERIAL PHOTOGRAPHY

Uses in War and Peace. Aircraft Photography in War and Peace, H. Hamshaw Thomas. Jl. Royal Soc. Arts, vol. 68, nos. 3543, 3544, Oct. 15 and 22, 1920, pp. 749–753 and 763–766. Oct. 15: Taking and production of aeroplane photographs. Cantor lectures; Oct. 22: Uses of aerial photography for securing military information. Graphic record of results of operations.

AEROPLANE ENGINES

B. M. W. IIIa. The 185-Hp. Bavarian Aeroplane Engine B.M.W. IIIa (Der 185 PS Bayern-Flugmotor B.M.W IIIa). Otto Schwager. Motorwagen, vol. 23, nos. 22, 23 and 24, Aug. 10, 20 and 31, 1920, pp. 399 404, 421–425 and 441–445, 14 figs. Six-cylinder engine with 150 mm. bore and 180 mm. stroke constructed along lines of the Mercedes engine, but differing from this, however, in the high degree of compression (6.5), and in the construction of the carburetor, in which the output of 185 hp. remains unchanged up to altitude of three km. Results of experiments are given in tabular form showing efficiency of aeroplane.

Fuels for. See GASOLINE, Alcogas Fuel vs.

Ignition. See IGNITION.

German. Development of German Aircraft Engines, Otto Schwager. Aviation, vol. 9, no. 6, Oct. 15, 1920, pp. 186–189, 4 figs. (Concluded.) Translated from Technische Berichte.

Machining. Machining Airplane Engine Parts. Machy. (N.Y.), vol. 27, no. 3, Nov. 1920, pp. 233–238, 11 figs. Tooling equipments and special indexing work-holding fixture used in connection with turret lathe practice of Alfred Herbert, Ltd., Coventry, England.

Rotary. French Rotary Airplane Engine Uses a Variable Stroke, W. F. Bradley. Automotive Industries, vol. 43, no. 18, Oct. 28, 1920, pp. 862–863, 2 figs. Damblanc type in which compression is changed by varying length of stroke.

Superchargers. Experiments with and Practical Use of Superchargers in Germany, Eric Hildesheim. Automotive Industries, vol. 43, no. 17, Oct. 21, 1920, pp. 810–816, 13 figs. Translated from Zeitschrift des Vereines Deutscher Ingenieure, Motorwagen and Flugsport.

Supercharging. Aeroplane Performances as Influenced by the Use of a Supercharged Engine, George De Bothezat. Aerial Age, vol. 12, no. 6, Oct. 18, 1920, pp. 174–179, 2 figs. Equations for calculating ceiling.

AEROPLANES

All-Metal. All-Metal Airplane Comprises Novel Engineering Features. Automotive Industries, vol. 43, no. 17, Oct. 21, 1920, pp. 808–809, 2 figs. Construction and performance of JL all-metal aeroplane. Chief mechanical features of design are self-supporting, deep sectioned, internally trussed wings.

The Short All-Metal "Silver Streak." Aviation, vol. 9, no. 7, Nov. 1, 1920, pp. 217–219, 3 figs. Specifications: Engine, Siddelay Puma; b.hp., 260; surface, 370, sq. ft.; span, 37 ft. 6 in.; length overall, 26 ft. 5 in.; height, 10 ft. 6 in.; total weight, 2870 lbs.; speed, maximum, 120 m.p.h.; climb, 10,000 ft. in 11 min.

British Air Ministry Competition. The Small Airplanes of the British Competition. Aviation, vol. 9, no. 6, Oct. 15, 1920, pp. 193–196. First report on British Air Ministry competition for commercial aircraft by Edward P. Warner, acting technical assistant in Europe of National Advisory Committee for Aeronautics.

Control Surfaces. The Design of Aeroplane Control Surfaces with Special References to Wing Ailerons, H. B. Irving. Eng., vol. 110, nos. 2858–2860, Oct. 8, 15, and 22, 1920, pp. 461–463, 493–494, and 527–528, 19 figs. Oct. 8: Aerodynamic properties of control surfaces. Factors which govern controlability of aeroplanes; Oct. 15: Comparison of efficiencies of control of ailerons on wings with differently shaped tips; and Oct. 22: Graphs showing rolling moment and hinge moment for ailerons of various chords.

Chassis, Retractable. Retractable Chassis as an Aid to Aeroplane Speed and Efficiency, Jas. V. Martin. Aerial Age, vol. 12, no. 10, Nov. 15, 1920, p. 274, 2 figs. Importance of retracting aeroplane chassis to increase speed. Tests are quoted in which speed was increased 30 miles an hour when chassis was retracted and extended.

Cost of Operating. The Operation of Civil Aircraft in Relation to the Constructor, H. White-Smith. Flight, vol. 12, no. 42, Oct. 14, 1920, pp. 1079–1088. Detailed study of cost of operating commercial service.

Dayton-Wright. The Dayton-Wright R. B. Racer Aviation, vol. 9, no. 6, Oct. 15, 1920, pp. 190, 1 fig. Dimensions: Span, 21 ft. 2 in.; overall length, 22 ft. 8 in.; total weight, loaded, 1850 lb.; cruising radius, 275 miles; ceiling, 15,000 ft.

Design. Analytical Process for Calculating the Polar Equation of an Aeroplane (Procédés analytiques pour le calcul des polaires d'avions), Maurice Le Sueur. L'Aérophile, vol. 28, nos. 15–16, Aug. 1–15, 1920, pp. 226–229. Analytical method claimed to be equally as precise as graphic method, and more rapid than the latter.

Flight, Conditions Governing. The Aerotechnical Institute of St. Cyr. Sci. Am. Monthly, vol. 2, no. 3, Nov. 1920, pp. 260–263, 110 figs. Apparatus for testing mechanical conditions governing flight of airplanes.

German Types. Linke-Hofmann Giant Aeroplanes—Type R-II. Aeronautics, vol. 19, no. 364, Oct. 7, 1920, p. 260. Multi-engined aeroplanes with engines centralized as one unit, developed by Linke-Hofmann Aeroplane Co., of Breslau, Germany.

Junkers. Cause of the Superiority of the Junkers Aeroplanes. (Was macht die Junkers-Flugzeuge überlegen). Luftfahrt, vol. 24, no. 9, Sept. 2, 1920, pp. 131–133, 5 figs. Said to be due partly to exclusive use of light metal, but principally to use of suspended, strutless aerofoils.

Laird Swallow. The Laird "Swallow." Aerial Age, vol. 12, no. 9, Nov. 8, 1920, pp. 253 and 259, 3 figs. Specifications: Span, 36 ft.; overall length, 23 ft. 4 in.; overall height, 8 ft. 8 in.; total supporting area, 324 sq. ft.; total weight, 1750 lb.; range at full speed, 255 miles, maximum speed, 86 m.p.h.; ceiling, 17,000 ft.

Landing Stations. Landing Fields are a Major Problem Development of Air Traffic. Automotive Industries, vol. 43, no. 19, Nov. 4, 1920, pp. 928–929. Present situation and suggested methods for improvement.

Martin Bomber. Trans-Oceanic Airplane. Sci. Am., vol. 123, no. 19, Nov. 6, 1920, pp. 471, 2 figs. Seven-ton Martin bomber under test by U. S. Army. Engine's speed is 2,000 r.p.m. and propeller speed 1,000.

Single vs. Twin-Engined. A Comparison of the Flying Qualities of Single and Twin-Engined Aeroplanes, R. M. Hill. Flight, vol. 12, no. 44, Oct. 28, 1920, pp. 1134–1136, and also Aeronautics, vol. 19, no. 367, Oct. 28, 1920, pp. 307–309. Comparison from pilot's point of view. Paper read before Roy. Aeronautical Soc.

Small Machines. De Pischof's "Avionnette." Aeronautics, vol. 19, no. 364, Oct. 7, 1920, p. 260, 1 fig.

per hour; maximum height, 500 ft.

Stress Analysis. Airplane Stress Analysis, A. F. Zahm and L. H. Crook. Nat. Advisory Committee for Aeronautics, report no. 82, 1920, 70 pp., 42 figs. Theory of aeroplane stress analysis taking into consideration forces within engine and propeller.

Sperry Amphibious Triplane. The Sperry Amphibious Triplane. Aviation, vol. 9, no. 7, Nov. 1, 1920, pp. 222–224, 2 figs. Specifications: Wing span, 48 ft.; depth of wing chord, 60 in.; gap between wings, 60 in.; length overall, 31 ft. 6 in.; height, 15 ft. 4 in.; total supporting surface, 678 sq. ft.; total weight, 5056 lbs.; engine, Liberty 12-cylinder V type 400 hp.; speed, 91 m.p.h.

Waterman Type. Waterman Type 3–L400 Airplane. Aviation, vol. 9, no. 6, Oct. 15, 1920, pp. 191–192, 2 figs. Dimensions: Speed, maximum, 126 m.p.h.; crusing speed, 105 m.p.h., engine, 400 hp. Liberty. weight, loaded, 4135 lb., climb, 10,000 ft. in 9 min.

Wings. The Handley Page Wing. Flight, vol. 12, no. 44, Oct. 28, 1920, pp. 1123–1125, 4 figs. Account of first public demonstration of patented high-lift wing.

The Handley Page Wing Patent. Aviation, vol. 9, no. 6, Oct. 15, 1920, pp. 197–199, 6 figs. Object of invention is to provide construction whereby burbling effect on back or upper surface of forward portion of wing can be overcome, so that same lift can be obtained at slower speeds than is now possible even when wing is inclined at greater angle to air.

AIRSHIPS

Commercial. The Commercial Airship—Its Operation and Construction, Trevor Dawson. Eng., vol. 110, no. 2860, Oct. 22, 1920, pp. 558–560. Airplane versus airship. Airship is found more advantageous for commercial service, and its traffic possibilities are pointed out. (Abstract.) Paper read at Air Conference, London, Oct. 14, 1920.

Rigid. The Aerial Cruiser. Sci. Am., vol. 123, no. 16, Oct. 16, 1920, pp. 400, 409 and 412, 3 figs. Particulars: Gross displacement, 38.25 tons; disposable lift, 17.80 tons; total b.hp. at full power, 1000; range in miles, full power, 3900; maximum height attainable with crew and stores, 17,000 ft.

[See also BALLOONS.]

ALCOHOL

Ethyl, from Wood Waste. The Manufacture of Ethyl Alcohol from Wood Waste, G. H. Tomlinson. Dominion of Canada, bul. no. 7, 1919, 9 pp. Chemical processes.

Waste Sulphite Liquor as Source. Canadian Waste Sulphite Liquor as a Source of Alcohol, Vernon K. Krieble. Dominion of Canada, report no. 5, 1919, 14 pp., 2 figs. A dozen representative Canadian sulphite liquors were analyzed. Results showed that best liquors contained as high a percentage of sugar as those produced in Europe. Yield from Canadian sulphite liquors is estimated at at least one per cent of alcohol by volume.

[See also AUTOMOBILE FUELS, Alcohol.]

ALLOY STEELS

Non-Expanding. Important Swiss Discovery Affecting Watchmaking. Commerce Reports, no. 260, Nov. 4, 1920, p. 569. C. E. Guillaume, director of International Bureau of Weights and Measures announces discovery of alloy steel which will experience no changes with variation in temperature. Alloy is a nickel steel with 12 per cent chrome.

Uranium and Chrome-Vanadium. Uranium as a Structural Steel Alloy, Hugh S. Foote. Ry. Mech. Engr., vol. 94, no. 11, Nov. 1920, pp. 695–696. Characteristics of uranium steel. Static and dynamic tests of uranium and chrome-vanadium steels.

ALLOYS

Molybdenum, Cobalt and Chromium. The Analysis of Molybdenum, Cobalt, and Chromium Alloys, J. R. Camp and J. W. Marden. Jl. Indus. and Eng. Chem., vol. 12, no. 10, Oct. 1920, p. 998. Results of series of analyses made on samples of metal obtained by alunimothermic reduction method.

Ternary. Ternary Alloys and the Equivalence Coefficients (Les alliages ternaires et les coefficients d'equivalence), Léon Guillet and Albert Portevin. Revue de Métallurgie, vol. 17, no. 8, Aug. 1920, pp. 561–567, 4 figs. Technical study. Special reference made to copper-aluminum-zinc alloys.

[See also ALUMINUM ALLOYS.]

ALTERNATORS

See ELECTRIC GENERATORS, A. C., Slow-Speed.

ALUMINUM

Atomic Weight. A Revision of the Atomic Weight of Aluminum. The Analysis of Aluminum Bromide. Preliminary Paper, Theodore W. Richards and Henry Krepelka. Jl. Am. Chem. Soc., vol. 42, no. 11, Nov. 1920, pp. 2221–2232, 1 fig. Synthesis and analysis of pure aluminum bromide. Atomic weight for aluminum is computed at 26.963.

Automobile Parts. Machining Aluminium Automobile Parts. Machy. (Lond.), vol. 17, no. 422, Oct. 28, 1920, pp. 97–101, 9 figs. Account of recent practice.

num-dust explosion and manner in which explosion occurred, and results of this investigation.

Nickel Plating of. Nickel-Plating Aluminum and Alloys. Sci. Am. Monthly, vol. 2, no. 3, Nov. 1920, p. 267. It was found in tests that sheet metal treated with fine ground sand and under pressure of 1500 grams per sq. cm. could be kept in good state if wrapped in sheet of filter paper for 30 days before being nickel-plated. Sheets of metal treated with sand blast under these conditions were nickel-plated up to 0.04 mm. Translated from Revue de Métallurgie.

ALUMINUM ALLOYS

Analysis of. A Rapid and Systematic Method for the Analysis of Light Aluminium Casting Alloys, Russell M. Berry. Jl. Indus. and Eng. Chem., vol. 12, no. 10, Oct. 1920, pp. 998–1000. Method developed at U. S. Navy Yard, Philadelphia, Pa.

No. 12 Alloy. Experiments in Manufacturing No. 12 Alloy, Robert J. Anderson. Chem. & Metallurgical Eng., vol. 23, no. 18, Nov. 3, 1920, pp. 883–887, 4 figs. It is concluded from experiments that No. 12 alloy may be conveniently and economically prepared by charging aluminum ingot, No. 12 ingot and scrap and copper-rich alloy into melting furnace, and that there is no advantage in any other procedure.

APPRENTICES, TRAINING OF

Engineering Apprentices. The practical Training of Engineering Apprentices [Die praktische Ausbildung der Ingenieurlehrlinge (Praktikanten)]. Betrieb, vol. 2, no. 15, Aug. 1920, pp. 413–415. Advice to machine industrials. Proposal of the German Committee for Technical Instruction.

German Works. The Apprentice School of the Thyssen & Co. Machine Factory, Mülheim-Ruhr (Aus der Lehrlingsschule der Maschinenfabrik Thyssen & Co., Mülheim-Ruhr, E. W. Seyfert. Werkstattstechnik, vol. 14, no. 15, Aug. 1, 1920, pp. 409–420. Conditions in training school are described which are said to be particularly interesting partly because it is a happy medium between municipal continuation schools and the purely technical training school, and partly because of its curriculum, effort being made to bring instruction in closest relationship with vocation of apprentice in order to stimulate his interest in learning. Sheets showing plan of instruction for the different classes are reproduced.

Machinists. A Worth-While Training Department, L. C. Morrow. Am. Mach., vol. 53, no. 20, Nov. 11, 1920, pp. 893–896, 3 figs. Methods at shop of American Tool Works, Co., Cincinnati.

Training Apprentices for Permanent Jobs, Norman G. Shidle. Automotive Industries, vol. 43, no. 19, Nov. 4, 1920, pp. 923–925, and p. 929, 3 figs. Training course for machinists operated for 40 years at works of Warner & Swasey Co., Cleveland.

Methods. Modernizing the Apprenticeship, Erik Oberg. Machy. (N.Y.), ol. 27, no. 3, Nov. 1920, pp. 220–224, 7 figs. Review of methods used by Taft-Pierce Mfg. Co., Woonsocket, R. I., in training apprentices along broad, comprehensive lines, intended to ultimately fit them for important position in mechanical industries.

Programs of Apprenticeship and Special Training in Representative Corporations—IV, J. V. L. Morris. Am. Mach., vol. 53, no. 19, Nov. 4, 1920, pp. 847–852, 8 figs. Methods of Westinghouse Electric Mfg. Co., East Pittsburgh, Pa.

Secondary Technical Education, F. H. Sexton. Jl. Eng. Inst. Canada, vol. 3, no. 11, Nov. 1920, pp. 505–509. Discussion of present and proposed methods of training in industry: vocational training, what it has accomplished in Great Britain and America, and part to be played by engineers.

ARCHES

Brick. Arch Brick Work, A. D. Williams. Iron Age, vol. 106, no. 20, Nov. 11, 1920, pp. 1264–1265, 1 fig. Formulæ and tables for fantail or taper arches.

ASPHALT

Gas vs. Oil for Melting. Taking All Factors into Consideration, Gas can be Proved Least Expensive as Well as Most Economical Fuel for Asphalt Melting C. H. Kallstedt. Am. Gas. Eng. Jl., vol. 113, no. 18, Oct. 30, 1920, pp. 345–348 and 350–351. Comparative costs of gas and oil. Advantages of using gas.

Refineries. The Largest Asphalt Refinery in the World. Mun. & County Eng., vol. 59, no. 4, Oct. 1920, pp. 130–132, 4 figs. Refinery operated by Texas Co. at Port Neches, Texas.

ATMOSPHERE

Electrical Phenomena at High Levels. Electrical Phenomena Occurring at High Levels in the Atmosphere, C. Chapman. Jl. Instn. Elec. Engrs. (Supp.), vol. 57, part 2, Oct. 1920, pp. 209–216 and (discussion) pp. 217–222, 4 figs. General outline of subjects based on published reports of observations.

AUTOGENOUS WELDING

Purity of Oxygen. Investigation of the Purity of Oxygen for Autogenous Welding (Untersuchung der Reinheit des Sauerstoffs fur Autogenschweisserein). Autogene Metallbearbeitung, vol. 13, nos. 14 and 15, July 15 and Aug. 1, 1920, pp. 157–162 and 175–177, 5 figs. Includes two tables giving

AUTOMOBILE ENGINES

Cam Grinding. A New Attachment for Grinding of Cams. Automotive Industries, vol. 43, no. 19, Nov. 4, 1920, pp. 921–922, 3 figs. Landis cam-grinding attachment.

Ignition. See IGNITION.

Starters. Electric Starting and Lighting of Automobiles (Éclairage et démarrage électriques des automobiles). Génie Civil, vol. 77, no. 14, Oct. 2, 1920, pp. 273–276, 5 figs. Bicompound dynamo built by Bleriot Works, Paris.

Impulse Starters. Automobile Engr., vol. 10, no. 143, Oct. 1920, pp. 417–418, 6 figs. Notes on new M–L device.

Tylor-Ricardo. The Tylor-Ricardo Engine. Automobile Engr., vol. 10, no. 143, Oct. 1920, pp. 386–393, 13 figs. Four-cylinder power unit for heavy vehicles. Description and results of road tests.

AUTOMOBILE FUELS

Acetol. New Motor Fuel in South Africa, Charles J. Pisar. Commerce Reports, no. 252, Oct. 26, 1920, p. 411. Particulars regarding acetol, a mixture of alcohol and ether with other ingredients.

Alcohol. Possible New Sources of Power Alcohol, C. Simmonds. Nature (London), vol. 106, no. 2660, Oct. 21, 1920, pp. 244–245. Report by Fuel Research Board, department of Scientific and Industrial Research.

Gasoline Substitute. Alternative Fuels. Eng., vol. 110, no. 2860, Oct. 22, 1920, pp. 543–544. Editorial comment on conflict in views presented at Fuel Section meetings of Imperial Motor Transport Conference held in London during Commercial Vehicle Exhibition.

Mixtures. Fuel Mixtures on London 'Buses, G. J. Shave. Motor Traction, vol. 31, no. 817, Oct. 25, 1920, pp. 493–494, 2 figs. Experiments carried out by London General Omnibus Co. Alcohol benzole, alcohol-ether, and alcohol-ether-benzol mixtures have been investigated.

[See also GASOLINE.]

AUTOMOBILES

Air Brakes. Air Brakes for the Automobile, C. W. Geiger. Sci. Am., vol. 123, no. 19, Nov. 6, 1920, pp. 467 and 480, 2 figs. System tested at Safety First Exposition held in conjunction with Nat. Traffic Officers' Convention at San Francisco. Air pressure is obtained from one cylinder of engine and is automatically maintained by means of accumulator valve with only one moving part.

Quantity Production. Machine Tool Practice as Applied to Motor-Car Production. Machy. (Lond.), vol. 17, no. 421, Oct. 21, 1920, pp. 68–75, 13 figs. Review of production methods employed by Vulcan Motor & Eng. Co. (1906), Ltd., Southport, England.

Warming Apparatus. Motor-Car Warming Apparatus. Eng., vol. 110, no. 2858, Oct. 8, 1920, pp. 472, 5 figs. Apparatus designed and constructed by Arc & General Equipment, Ltd., Engineers, London.

Wheels. Single-Disc Metal Wheels, A. L. Putnam, Jl. Soc. Automotive Engrs., vol. 7, no. 5, Nov. 1920, p. 437 and (discussion) p. 442. Advantages.

Wire Wheels, C. S. Walker. Jl. Soc. Automotive Engrs., vol. 7, no. 5, Nov. 1920, pp. 441–442, 4 figs. Advantages and disadvantages.

Wood Truck Wheels, S. Vance Lovenstein. Jl. Soc. Automotive Engrs., vol. 7, no. 5, Nov. 1920, pp. 438–440 and (discussion) pp. 442–445, 2 figs. Advantages and disadvantages. Results of strength tests.

AVIATION

Aerial Mail Service. Aerial Postal Service (La voie postale aérienne), Georges Brunel. L'Aérophile, vol. 28, nos. 15–16, Aug. 1–15, 1920, pp. 240–245. Survey of developments throughout the world.

Mail Transport, P. L. Holmes. Aeronautics, vol. 19, no. 366, Oct. 21, 1920, pp. 293–294. Cooperation of aircraft and surface craft.

Aerial Transportation. Time Table and Tariff of Air Companies Operating at Paris. Aeronautics, vol. 19, no. 364, Oct. 7, 1920, p. 262. There are four companies operating between Paris-London; one between Paris and Geneva; one between Toulouse and Bordeaux; two between Paris and Brussels; one between Toulouse and Montpellier; and one between Toulouse and Agen.

Alaskan Expedition. The Alaskan Flying Expedition. Flying, vol. 9, no. 10, Nov. 1920, pp. 626–630, 3 figs. Records of flight.

British Air Ministry. The Air Conference. Eng., vol. 110, nos. 2859 and 2860, Oct. 15 and 22, 1920, pp. 512–515 and 528–532. Proceedings of Air Conference called by Air Ministry for purpose of discussing technical and economic problems connected with aviation. (Abstract.)

Civil. Civil Aviation and Air Services, S. H. Sykes. Eng., vol. 110, no. 2859, Oct. 15, 1920, pp. 524–526. Growth and present position of air mail passenger and goods services in British Empire, France and United States. (Abstract.) Paper read at Air Conference at London, Oct. 12, 1920.

Contests. Two Great Aviation Contests in 1920 (Deux grandes épreuves d'aéronautique de 1920). Génie Civil, vol. 77, no. 17, Oct. 23, 1920, pp. 325–

ENGINEERING INDEX (Continued)

328, 8 figs. Contest for the Gordon-Bennett Cup held on Sept. 28, and the Buc Meeting, Oct. 8–10.

Key West-Havana Route. Key West-Havana Route Inaugurated. Aviation, vol. 9, no. 7, Nov. 1, 1920, pp. 226–227 and p. 230, 3 figs. Aircraft used is development of F-5-L flying boats which United States Government produced during the war for extended anti-submarine patrols both in home waters and in North Sea.

[See also FLIGHT.]

AVIATORS

Physiological Phenomona at High Altitudes. Aviators at High Altitudes (Les aviateurs aux hautes altitudes), Jacques Boyer. Nature (Paris), no. 2422, Sept. 4, 1920, pp. 145–148, 3 figs. Physiological experiments at French Aerotechnical Inst.

B

BALLOONS

Dilatable. Dilatable Balloons, James F. Boyle. Aviation, vol. 9, no. 6, Oct. 15, 1920, pp. 184–186, 6 figs. Balloons recently built and tested by War Department.

Hydrogen-Helium Mixtures for. Inflammability of Jets of Hydrogen and Inert Gas, P. G. Ledig. Jl. Indus. & Eng. Chem., vol. 12, no. 11, Nov. 1920, pp. 1098–1100, 4 figs. Experimental work to determine maximum amount of hydrogen which can be used with helium in balloons without losing advantage of noninflammability. Up to 18 to 20 per cent of helium was found to be safe proportion.

BARGES

Adjustable Prow. French Devise Adjustable Prow to Increase Speed of Barges. Eng. News-Rec., vol. 85, no. 18, Oct. 28, 1920, pp. 851–852, 2 figs. Resistance lowered 23 per cent in tests made with folding panels that sharpen barge's flat bow. Translated from Annales des Ponts et Chaussées.

BATTERIES

Clark Standard Cell. The Two Common Failures of the Clark Standard Cell, E. C. McKelvy and M. P. Shoemaker. Sci. Papers, Bur. of Standards, no. 390, July 21, 1920, pp. 409–420, 8 figs. Cracking at amalgam terminal is remedied by employing platinum wire previously subjected for a short time to the action of hot ten per cent zinc amalgam, using lead sealing-in glass. Interruption of circuit by gradual formation of gas in amalgam limb is reduced by using smallest excess of crystals required to insure saturation at highest temperature at which cell is likely to be used.

Dry Cells, Testing. Automatic Apparatus for Intermittent Testing, G. W. Vinal and L. M. Ritchie. Technologic Papers, Bur. of Standards, no. 171, July 22, 1920, 7 pp. 6 figs. Apparatus devised at Bureau of Standards for making tests of dry cells and storage batteries. It is applicable to any form of intermittent test requiring closing of electrical circuits at regular time intervals.

New Cell. A New Electric Battery (Une nouvelle pile électrique), A. Troller. Nature (Paris), no. 2424, Sept. 18, 1920, pp. 180–181, 1 fig. Leclanché type with electrodes arranged to permit depolarization of oxygen of atmosphere.

BEAMS

Bending Moments. A Self-Checking String Polygon, Theodore Bleckmann. Eng. News-Rec., vol. 85, no. 19, Nov. 4, 1920, pp. 880–881, 3 figs. Graphical method in which paralleling is replaced by measurement.

Cantilever. The Calculation of the Deformation of Cantilever. Beam Systems (Beitrag zur Berechnung der Formänderung von Kragträgersystemen), Eduard Cecerle. Eisenbau, vol. 11, no. 17, Sept. 3, 1920, pp. 296–313, 14 figs. Method according to which the elastic weights are calculated from the internal forces (deformations) due to load (change of temperature, etc.); with these weights the described reciprocal beam system is loaded; and line of moments of the elastic weights is the bending line. Includes table for calculation of bending line.

[See also GIRDERS.]

BEARINGS, BALL

Roller and. What is the Difference Between Roller and Ball Bearings, A. Danielson. Am. Mach., vol. 53, no. 19, Nov. 4, 1920, pp. 857–858, 5 figs. Suggestions for definite classification of these two types.

BELTING

Substitutes. Investigation of Substitute Belts (Untersuchung von Ersatzriemen), H. Schlesinger and M. Kurrein. Werkstattstechnik, vol. 14, nos. 14 and 15, July 15, and Aug. 1, 1920, pp. 385–388 and 420–426, 18 figs. Account of tests on various types of belts to determine their adaptability, etc., and description of test arrangements. Results are given in tables and charts and show that braided belts give the poorest and twill texture the best results. Report from machine-tool testing station of the Berlin Technical Academy.

BENZOL

Recovery from Coal Gas. The Recovery of Vapours from Gases Particularly of Benzene and Toluene from Coal Gas, Harold S. Davis and Mary Davidson Davis. Dominion of Canada, report no. 2, 1918, 15 pp., 2 figs. Results of research carried out in University of Manitoba, and of tests conducted at Light Oil Recovery Plant of Toronto Chemical Co.

BLAST-FURNACE GAS

Cleaning. Cleaning Blast-Furnace Gas, A. Hutchinson and E. Bury. Eng., vol. 110, no. 2857, Oct. 1, 1920, pp. 453–456, 4 figs. Rough-cleaning of blast-furnace gas at Skinningrove by the Lodge Electrostatic Process. Paper read before Iron & Steel Inst.

Power Production from. The Production of Power from Blast-Furnace Gas, S. H. Fowles. Jl. Instn. Elec. Engrs., vol. 58, no. 292, June 1920, pp. 431–436, and (discussion) pp. 437–463, 3 figs. Survey of old and new methods of utilization of waste heat.

BLAST FURNACES

Heat Supplied to. The Effect of Heat Supplied to the Blast Furnace, W. W. Hollings. Eng., vol. 110, no. 2857, Oct. 1, 1920, pp. 459–460. Variations in heat supplied to blast furnace, and their effect on fuel consumption. Paper read before Iron & Steel Inst.

Large Hearths. Development of Large Furnace Hearth, Walter Mathesius. Blast Furnace & Steel Plant, vol. 8, no. 11, Nov. 1920, pp. 588–592, 6 figs.; Chem. & Metallurgical Eng., vol. 23, no. 18, Nov. 3, 1920, pp. 867–872, 6 figs.; Iron Trade Rev., vol. 67, no. 18, Oct. 28, 1920, pp. 1211–1213, 6 figs.; and Iron Age, vol. 106, no. 18, Oct. 28, 1920, pp. 1106–1109, 1 fig. Wide hearth permits steeper bosh and flatter stack lines with many resulting economies, especially for smelting Mesaba ores. Operating data, construction details and theoretical considerations point to its definite superiority. Paper read before Am. Iron and Steel Inst.

Remodeling. Rebuilt Furnace Conserves Labor. Iron Trade Rev., vol. 67, no. 17, Oct. 21, 1920, pp. 1123–1126, 5 figs. How capacity of furnace of Belfont Iron Works Co., Ironton, O., was increased two-thirds.

Remodeled Blast Furnace at Ironton, Ohio, F. H. Willcox. Blast Furnace & Steel Plant, vol. 8, no. 11, Nov. 1920, pp. 599–602, 3 figs. How capacity of blast furnace has been increased two-thirds.

Stack Design. Designs Stack for Foundry Iron. Iron Trade Rev., vol. 67, no. 16, Oct. 14, 1920, pp. 1068–1070, 4 figs. Bosh is cooled by series of louvers which keep film of water flowing over entire jacket. Big bell suspended from yoke on account of filling system. Charge weighted on floor-type scale.

BOILER FEEDWATER

Automatic Regulator for. An Automatic Feed Regulator. Engr., vol. 130, no. 3380, Oct. 8, 1920, p. 352, 3 figs. Manufactured by A. G. Mumford, Ltd., Colchester, England. Regulator acts directly on feed check valve and relies for its effect on control of leakage past piston connected with valve.

Testing. Simple Methods of Determining Dissolved Gas Content in Boiler-Feed Water, J. R. McDermet and Daniel Wertheimer. Power, vol. 52, no. 18 Nov. 2, 1920, pp. 686–688, 3 figs. Methods which do not require special laboratory glassware or skilled operator.

BOILER FIRING

Lean Gas as Fuel. Lean Gas as Boiler Fuel. Iron Age, vol. 106, no. 20, Nov. 11, 1920, pp. 1261–1262, 1 fig. Low grade coals used in coke ovens and coke utilized in gas producers. Experiments carried on by Société deséres de Montrambert et de la Béraudière at St. Étienne, France.

BOILERS

Electrically Heated. Recent Developments of Electrically Heated "Revel" Boilers in Switzerland, E. G. Constam-Gull. Eng., vol. 110, no. 2861, Oct. 29, 1920, pp. 563–565, 4 figs. Revel boiler has overall diameter of 24 in. and total height of 8 ft. It produces 1200 lb. of steam per hour at gage pressure of 225 lb. per sq. in. when supply current is at 500 volts. Efficiency corresponds to evaporation of 2.8 lb. of standard steam per kilowatt-hour. Evaporation and heating of steam is accomplished within immediate vicinity of water level.

Gas-Fired. French Experience with Gas-Fired Boiler Installation Demonstrates Possibility of Complete Combustion of Low B.t.u. Gas Without Preheating Supporting Air, John H. Bartlett, Jr. Am. Gas Eng. Jl., vol. 113, no. 17, Oct. 23, 1920, pp. 321–324, 2 figs. Installation made by French Company, employing patented process and equipment of Surface Combustion Co. of New York.

Use of Gas Fired Boilers, C. M. Grow. Gas Rec., vol. 18, no. 7, Oct. 13, 1920, pp. 39–42. Appliances for domestic and commercial heating on Pacific coast. Paper read before Pacific Coast Gas Assn.

Industrial Code. Rules as Amended Relating to the Construction, Installation, Inspection and Maintenance of Steam Boilers. Bul. no. 14, Industrial Code, State of New York, Dept. of Labor, State Industrial Commission, 148 pp., 33 figs. Rules amended and readopted to become effective July 1, 1920.

Oil-Fired. Soot Deposits in Oil-Fired Boiler, Robert June. Power Plant Eng., vol. 24, no. 22, Nov. 15, 1920, pp. 1061–1063, 2 figs. Description of tests indicating advisability of equipping oil-fired boilers with soot blowers.

Patches. Design of Patches. Universal Engr., vol. 32, no. 4, Oct. 1920, pp. 38–40, 1 fig. Factor diagram for diagonal patch seams on bottoms of horizontal return tubular boilers.

Temperature Measurements. Temperature Measurements with Special Regard to Steam-Boiler Investigations (Einiges über Temperaturmessungen, insbesondere bei Dampfkesseluntersuchungen), H. Hilliger. Zeitschrift für Dampfkessel u. Maschinenbetrieb, vol. 43, nos. 33, 34, 35 and 36, Aug. 13, 20, 27 and Sept. 3, 1920, pp. 249–251, 257–260, 267–269 and 275–276, 14 figs. Discusses work by Knoblauch and Hencky on the accurate technical temperature measurements with liquid and electric thermometers, and other viewpoints and experiences in connection with furnace and steam-boiler investigations.

Through Stays. A Limiting Formula for Long Through Stays, John S. Watts. Boiler Maker, vol. 20, no. 10, Oct. 1920, pp. 297–298, 1 fig. Discussion of method of determining proper sizes of through stays in boilers. Chart developed to simplify calculations.

Tubes. The Constitution and Properties of Boiler Tubes, Albert E. White. Mech. Eng., vol. 42, no. 11, Nov. 1920, pp. 603–606, and p. 618. Experimental investigations carried out at Detroit Edison Co. Causes of failure of boiler tubes were found to be: (1) Failure due to tube brittleness resulting from absorption of hydrogen by metal; (2) failure due to blowholes or other imperfections in metal, and (3) failure due to recrystallization of metal. Further study disclosed that increased carbon content in tubes would insure longer life and safer boiler operation. It is suggested that carbon content should vary between 0.30 and 0.35 per cent.

BORING MACHINES

Heavy-Duty. Heavy-Duty Boring Machine. Machy. (N.Y.), vol. 27, no. 3, Nov. 1920, pp. 259–260, 3 figs. Machining headstock and tailstock castings for ninety-inch driving wheel lathes.

Milling Attachment for. Vertical Boring Mill with Milling Attachment (Karusseldrehwerk mit Fräsvorrichtung), H. Weil. Zeit. des Vereines deutscher Ingenieure, vol. 64, no. 39, Sept. 25, 1920, pp. 793–794, 8 figs. Describes machine with table 4500 mm. in diam. built by the Schiess machine factory, Düsseldorf, and equipped with a special milling attachment. Shows that such special arrangements can be advantageously applied, and that in certain cases they save the installation of a new machine.

BRACKETS

Design. Stresses in Brackets and Their Bolts, Victor M. Summa. Machy. (N.Y.), vol. 27, no. 3, Nov. 1920, pp. 239–241, 4 figs. Formula for computing stresses, bending moment diagrams, etc.

BRASS

Melting with Fuel Oil. Melting Brass with Fuel Oil—I, S. D. Rickard. Metal Industry (N.Y.), vol. 18, no. 10, Oct. 1920, pp. 460–463, 2 figs. Analysis of costs and comparison with other fuels, showing that fuel oil is most economical.

BRIDGES, HIGHWAY

Reconstruction. Strengthening and Reconstructing Highway Bridges for Heavy Motor Truck Traffic. Eng. & Contracting, vol. 54, no. 17, Oct. 27, 1920, pp. 412–414. Progress report of Committee of American Road Builders' Association.

BRIDGES, LIFT

Bascule. A New Type of Bascule Span in the Highway Bridge over the Eider River Near Friedrichstadt (Neuartige Klappbrücke in der Strassenbrücke über die Eider bei Friedrichstadt). Zentralblatt der Bauverwaltung, vol. 40, no. 61, July 31, 1920, pp. 386–387, 6 figs. Describes an electrically driven, two-leaf bascule span with fixed axis of rotation. Points out advantages of two-leaf over single-leaf bridges.

BRIDGES, MOVABLE

Electric Operation. Electric Operation of Movable Bridges (La manœvre électromécanique des ponts mobiles), Joseph Chanteux. Annales des Travaux publics de Belgique, vol. 21, no. 4, Aug. 1920, pp. 515–594, 45 figs. on 15 supp. plates. General theory. Design formulæ. Three types are considered: Lift bridges; turning bridges; and bascule bridges. (To be continued.)

[See also BRIDGES, LIFT.]

BRIDGES, RAILWAY

Poland, Official Regulations. Official Regulations for the Construction of Railway Bridges in Poland (La réglementation officielle des ponts-routes en Pologne), Maximilien Thublie. Génie Civil, vol 77, no. 15, Oct. 9, 1920, pp. 293–295, 9 figs. Classification of bridges. Elastic limits permissible.

Reconstruction. Heavy Spans to be Rolled and Jacked in Difficult Bridge Reconstruction. Eng. News-Rec., vol. 85, no. 19, Nov. 4, 1920, pp. 904–907, 3 figs. New double-track structure of increased load capacity provides wider channel openings and greater clearance height. Erection under traffic. Will shift track to higher elevation in one day.

Specifications. New Steel Railway Bridge Specification. Can. Engr., vol. 39, no. 17, Oct. 21, 1920, pp. 443–445. Canadian Engineering Standards Association issues specification for bridges not exceeding 500-ft. span based on draft prepared by Engineering Institute. Cooper's loadings and American Railway Engineering Association's impact formula adopted. Secondary stress computation optional. Parabolic column formula. Movable bridges.

BRIDGES, WOODEN

Poland. Construction of the Bridge over the Dubiss

Gustavsburg, of wooden bridge, about 700 m. long and 40 m. high, having nine openings spanned by superstructures of 62.40 m. each, in the form of parallel trussed girders with diagonals rising and falling alternately.

BRONZES

Manganese. Note on a Failure of "Manganese Bronze," J. H. S. Dickenson. Eng., vol. 110, no. 2860, Oct. 22, 1920, pp. 556–558, 15 figs. Experimental study of conditions under which alloys of manganese-bronze type are prejudicially affected by contact with fluid solder and effect of variation in composition and microstructure. Paper read before Inst. of Metals.

BUILDING CONSTRUCTION

See WALLS.

C

CARBON BLACK

Manufacture. The Disk, Plate and Cylinder Processes for the Production of Carbon Black, Roy O. Neal. Chem. & Metallurgical Eng., vol. 23, no. 16, Oct. 20, 1920, pp. 785–789, 8 figs. Description with mechanical details of disk, plate and cylinder process carbon black plants. Driving mechanism and heat variations. Comparison of processes.

CARBURETORS

Fuel-Feeding Devices. The N. K. F. Vacuum Fuel Feeder (Der N. K. F.-Unterdruck-Brennstofförderer), Wa. Ostwald. Allgemeine Automobil-Zeitung, vol. 21, no. 28, July 10, 1920, pp. 26–27, 1 fig. Describes fuel-feeding device which is said to have the advantage that the carburetor is always provided with fuel at starting of motor and is never without fuel when climbing a hill. The two chambers are constructed, not one above the other, but one within the other.

Various Construction Types of Vacuum Fuel Feeding Devices (Verschiedene Bauarten bei der Unterdruck-Förderung des Brennstoffs), H. v. Löw. Allgemeine Automobil-Zeitung, vol. 21, no. 26, June 26, 1920, pp. 29–30, 7 figs. Describes working method of such apparatus.

CARS

Buffers. A Self-Contained Railway Buffer with Non-Breakable Shank. Ry. Gaz., vol. 33, no. 17, Oct. 22, 1920, p. 550, 2 figs. Railway buffer fitted with George Spencer Moulton & Co.'s patent rubber spring.

Tipping. Railway Loading and Off-Loading Arrangements, H. Aumund. Eng. Progress, vol. 1, no. 10, Oct. 1920, pp. 309–313, 13 figs. Problems of rail transport. Railway tipping cars and their various designs. Arrangement, construction, application, and capacity of new portable tipping device. Comparison with automatic tipping arrangements.

Weighing Machines. A New Railway Wagon Weighing Machine, T. J. Primrose. Ry. Engr., vol. 41, no. 490, Nov. 1920, pp. 454–455, 5 figs. Apparatus for measuring load on locomotive and car wheels with object of finding pressure with which wheels bear upon rails.

CARS, PASSENGER

Pullman Improvements. Improvements in New Pullman Sleepers. Ry. Age, vol. 69, no. 16, Oct. 15, 1920, pp. 661–664, 9 figs. Changes in details which have been developed to add to comfort and safety of travel.

CAST IRON

Nickel and Cobalt, Effect of. The Influence of Nickel and Cobalt Additions on the Physical and Chemical Properties of Cast Iron (Der Einfluss eines Nickel- und Kobaltzusatzes auf die physikalischen und chemischen Eigenschaften des Gusseisens), O. Bauer and E. Piwowarsky. Stahl u. Eisen, vol. 40, no. 39, Sept. 30, 1920, pp. 1300–1302, 3 figs. Results of investigations are given in tabular form, from which it is concluded that for production of high-grade castings for machine parts, gear wheels, etc., a nickel addition up to 1.2 per cent can be thoroughly recommended, but an addition of cobalt for the refining of cast iron is not feasible. Report from Metallurgical Inst. of Technical Academy of Breslau.

CEMENT GUN

Fireproofing with. Tests Show that Buildings May Be Rendered Fireproof with Gunite, B. C. Collier. Coal Age, vol. 18, no. 19, Nov. 4, 1920, pp. 939–942, 3 figs. Tests made by Anaconda Copper Mining Co. and at Underwriters Laboratory in Chicago.

CENTRAL STATIONS

Cuba. Central-Station Operation in Tropical America, L. E. Gowling. Power, vol. 52, no. 16, Oct. 19, 1920, pp. 606–609, 5 figs. Central station in Havana, Cuba. Plant supplies current for operation of electric railway and electric light and power service for city of Havana.

Electrical Equipment. The Electrical Equipment of the Golpa Central Station (Die elektrischen Einrichtungen des Kraftwerkes Golpa), Heinrich Probst. Elektrotechnische Zeitschrift, vol. 41, nos. 34 and 35, Aug. 26 and Sept. 2, 1920, pp.

Middle West. Power Service for a Middle West Section, Lyle A. Whitsit. Elec. World, vol. 76, no. 20, Nov. 13, 1920, pp. 969–971, 2 figs. Survey in Western Pennsylvania and Eastern Ohio by power section of War Industries Board indicates aggregate power peak demand during 1918 of 568,000 kw. and total central-station output in this district of 2,440,000,000 kw-hr. Estimated increased peak load of 1,000,000 kw. by 1927.

CHEMICAL INDUSTRY

Sweden. Chemical Industry and Trade of Sweden, O. P. Hopkins. Jl. Indus. & Eng. Chem., vol. 12, no. 11, Nov. 1920, pp. 1045–1054. Statistics showing strengthening of industries since 1914.

CHROME-NICKEL STEEL

See ALLOY STEELS, Non-Expanding.

COAL

Conservation. George Otis Smith on Thrift in Coal. Iron Age, vol. 106, no. 18, Oct. 28, 1920, pp. 1122–1124, 3 figs. Suggestions for economical use of coal in steel industry and by railroads. Paper read before Am. Iron & Steel Inst.

Thrift in Coal, George Otis Smith. Power, vol. 52, no. 18, Nov. 2, 1920, pp. 716–718, 3 figs. Suggestions in regard to coal combustion. Paper read before Am. Iron and Steel Inst.

Distillation of. The Low-Temperature Distillation of Coal in a Revolving Kiln (Die Tieftemperaturentgasung der Kohle im Drehofen), H. Gwosdz Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 43, no. 35, Aug. 27, 1920, pp. 265–267, 1 fig. Account of distillation tests in a large revolving kiln, 24 m. long and 2 1/2 m. in diameter, into one end of which the fuel is fed while from the other end the semi-coke is carried out. Favorable results were obtained.

Mixtures. Graphic Method of Determining Proportions of Coal Mixtures, Edward J. Clarke. Power Plant Eng., vol. 24, no. 22, Nov. 15, 1920, p. 1066, 1 fig. Chart for determining proportions of coal mixtures.

Oil vs. Coal Versus Oil Performance Chart, L. C. Lichty. Indus. Management, vol. 60, no. 5, Nov. 1920, pp. 351–352, 5 figs. Calculations are based on cost per ton of coal delivered at plant, its heating value and efficiency of boiler plant when burning coal, in comparison with results determined by making use of density of oil fuel, heating value per barrel, cost per barrel delivered and efficiency when burning fuel.

Supply. The Problems of Coal Supply, Eugene McAuliffe. Elec. Ry. Jl., vol. 56, no. 16, Oct. 16, 1920, pp. 754–759, 5 figs. It is said that storage at point of consumption will improve "load factor" of fuel production and distribution. It is believed that national legislation providing for seasonal variation in coal-haulage rates would encourage uniformity of demand for coal and reduce mining costs. (Abstract.) Paper read before Am. Elec. Ry. Assn.

COAL BREAKERS

Dry Treatment. Preparing Anthracite for Market Without the Use of Water, Dever C. Ashmead. Coal Age, vol. 18, no. 19, Nov. 4, 1920, pp. 935–938, 8 figs. It is claimed that mechanical equipment and dust suckers render dry treatment almost as free from dust as wet preparation.

COAL GAS

Detarring. The Detarring of Gas by Electrical Precipitation, J. G. Davidson. Dominion of Canada, report no. 3, 1918, 45 pp., 4 figs. Report of experimental work. Successful tests of process of electrical precipitation for detarring of gas on commercial scale were made in wood, coal and petroleum distillation plants.

COAL MINES

Bituminous, Gas Explosion Prevention. Rules for Prevention of Gas Explosions, R. A. Walter. Coal Age, vol. 18, no. 19, Nov. 4, 1920, pp. 945–947. Rules based on writer's experience gained in bituminous coal mines as mine owner and manager for many years. Paper read before Ninth Annual Safety Congress.

COAL MINING

Difficulties Overcome. By New Operating Methods Estimated Life of Seneca Colliery has been Tripled, Dever C. Ashmead. Coal Age, vol. 18, no. 17, Oct. 21, 1920, pp. 839–845, 8 figs. Many difficulties, such as subterranean outcrops in glacial drift, mining under river beds, large inflow of water and one bed squeezed over practically entire area, have been encountered and surmounted in operating this mine.

COAL STORAGE

Fire Hazard. A Few of the Less Emphasized Causes Why Fine Sizes Ignite Soft-Coal Piles, O. P. Hood. Coal Age, vol. 18, no. 17, Oct. 21, 1920, pp. 845–848, 8 figs. One ton of coal in solid exposes 47 sq. ft. of surface to air. Crushed so as to pass sixteen-mesh sieve it exposes about one acre of surface. Extent and freshness of surface exposed and rapidity of ventilation are chief factors governing spontaneous heating. (Abstract.) Address delivered before Pennsylvania Elec. Assn.

Fire Prevention. The Storage of Coal, W. D. Langtry. Power, vol. 52, no. 18, Nov. 2, 1920,

Advantages as Fuel. Coke in Relation to Cheap Power, Transport and Smoke Abatement, E. W. L. Nicol. A Thousand and One Uses for Gas (Supp.), vol. 8, no. 81a, pp. 4–20, 20 figs. Advantages of coke as fuel. Performance record of coke-fired boilers.

Hydrogen as Desulphurizing Agent. The Desulfurizing Action of Hydrogen on Coke, Alfred R. Powell. Jl. Indus. & Eng. Chem., vol. 12, no. 11, Nov. 1920, pp. 1077–1081, 1 fig. Curves showing elimination of sulphur as hydrogen sulphide from coal when coked under different conditions.

COKE MANUFACTURE

Reactions in. A Study of the Reactions of Coal Sulfur in the Coking Process, Alfred R. Powell. Jl. Indus. & Eng. Chem., vol. 12, no. 11, Nov. 1920, pp. 1069–1077, 3 figs. Experimental studies at Bureau of Mines.

COKE OVENS

Rotating. Low-Temperature Distillation of Coal in Rotating Coke Oven, Ing. E. Roser. Power, vol. 52, no. 17, Oct. 26, 1920, pp. 678–679, 1 fig. Low-temperature tar is reported to yield 90 per cent bitumens in coal as against 50 per cent under present methods. Translated from Stahl und Eisen.

COLLOIDS

Colloid Mill. Colloidal Chemistry and a "Colloid Mill." Eng., vol. 110, no. 2857, Oct. 1, 1920, pp. 429–430. New Type of fine grinding disintegrator or "colloid" mill claimed to be ideal apparatus for extremely fine grinding required for homogenizing and dissolving substances and for obtaining emulsions and colloidal preparations. Translated from Chemiker-Zeitung.

COMBUSTION

Initial Gas Temperature. The Importance of the Initial Gas Temperature and Scientific Stoking (Die Bedeutung der Anfangstemperatur und die feurungstechnische Kritik), J. Hudler. Zeitschrift des Vereines deutscher Ingenieure, vol. 64, no. 40, Oct. 2, 1920, pp. 810–814, 2 figs. It is shown that for maintenance of a certain hour-output of a given boiler furnace plant, every increase of initial temperature causes a decrease of temperature of gases on leaving flue, which is brought about by reducing rate of combustion; increase of initial temperature also signifies reduction of chimney losses in temperature and volume of flue gases. The true ratio of value of different fuels, such as peat and peat dust, to anthracite is calculated.

COMPASSES

Gyroscopic. Principles of the Gyro-Compass, George B. Crouse. Mech. Eng., vol. 42, no. 11, Nov. 1920, pp. 619–623, 16 figs. Problems of design, special compensation of disturbing factors, methods of suspension and methods of damping.

COMPRESSED AIR

Pneumatic Mail Despatch. Pneumatic Mail Despatch in the Municipality of Berlin, Postbaurat Kasten. Eng. Progress, vol. 1, no. 10, Oct. 1920, pp. 305–308, 5 figs. Alternating air-current service with double-tube line, each tube for one direction only. Connection between old and new central telegraph office in Berlin. Equipment and switch connections. Graphic reproduction of pressure in tube.

CONCRETE

Pavement Slabs. Study of Temperature Stresses in Rigid Pavement Slabs, C. H. Scholer. Eng. News-Rec., vol. 85, no. 20, Nov. 11, 1920, pp. 943–944, 3 figs. Research at Engineering Experiment Station of Kansas State Agricultural College.

CONCRETE CONSTRUCTION

Marine Structures. The Durability of Maritime Structures. Nature (London), vol. 106, no. 2660, Oct. 21, 1920, pp. 235–236. Report of Committee of Instn. of Civil Engrs., appointed to investigate deterioration of structures of timber, metal and concrete exposed to action of sea water.

CONCRETE CONSTRUCTION, REINFORCED

Coal Mines. Ferro-Concrete Pit-Head Frame at Bently Colliery, Doncaster. Eng., vol. 110, no. 2859, Oct. 15, 1920, pp. 498–501, 71 figs. partly on supp. plate. Main building is about 132 ft. long by 32 ft. wide, with height, from foundations to roof of 64 ft.

Supports. Determination of Stress in Reinforced-Concrete Supporting Parts of any Given Cross-Section with Inclined Loading (Spannungsermittlung bei Eisenbetontragteilen beliebigen Querschnitts mit schrägem Lastangriff), G. Hartschen. Beton u. Eisen, vol. 19, no. 14, Sept. 4, 1920, pp. 167–169, 3 figs. Supplementary to author's article in no. 17–18, 1918, of same journal. Formulæ are derived for determination of main tensions for reinforced-concrete supports with inclined load, under two conditions, namely, when position of main axis of cross-section is known and when it is unknown.

CONCRETE, REINFORCED

Flat-Slab. Diagram for Flat Slab Design, O. Wolpert. Eng. & Contracting, vol. 54, no. 17, Oct. 27, 1920, p. 411, 1 fig. Diagram for estimating amount of reinforcing steel and thickness of slab required by New York City 1920 regulations.

ENGINEERING INDEX (Continued)

Liquid Mixtures. Liquid Concrete Mixtures for Reinforced-Concrete (Flussige Betongemische für Eisenbeton), H. Amos. Beton u. Eisen, vol. 19, no. 14, Sept. 4, 1920, pp. 164–167. Discussion of report on experiments in Royal Material-Testing Station, Berlin-Lichterfelde by Director M. Gary, from which following conclusions are drawn: Iron molds, heretofore commonly used, are not feasible for liquid concrete mass; wooden molds exhibit uncertainties in test; plaster molds produce samples whose strength is almost equal to that of concrete.

CONDENSERS, ELECTRIC

Electrostatic. Electrostatic Condensers, V. E. Goodwin. Jl. Am. Inst. Elec. Engrs., vol. 39, no. 11, Nov. 1920, pp. 976–983, 13 figs. Fundamental characteristics of condensers and their relation to electric circuits containing inductance and resistance. Effects of switching condensers on and off such circuits. Applications of condensers.

CONDUITS

Concrete. Casting and Steaming Reinforced Pipe. Public Works, vol. 49, no. 16, Oct. 16, 1920, pp. 358–360, 6 figs. Fabricating and seasoning in contractor's yard ten miles of reinforced concrete pipe 5½ ft. in diameter and 8 in. thick.

Reinforced-Concrete Pressure Pipes in Hydroelectric Plants (Druckrohre aus Eisenbeton bei Wasserkraftanlagen), Leo Nagel. Beton u. Eisen, vol. 19, no. 14, Sept. 4, 1920, pp. 153–155, 6 figs. Description of 1.4-km. pipe line in hydraulic plant of the Perlmooser Corp., Kirchbichl-Tirol, with diameter of 2.20 m. and pressure of 2 atmos., demonstrating economic advantages of use of reinforced-concrete pressure pipes.

CONNECTING RODS

Machining. Machining the Connecting Rods of Two Well Known Motors, Fred H. Colvin. Am. Mach., vol. 53, no. 19, Nov. 4, 1920, pp. 829–834, 20 figs. Method of manufacturing connecting rods for Oakland and Studebaker motors.

CONTRACTS

Cost Plus. Dam Contract Has Special Cost-Plus Feature. Eng. News-Rec., vol. 85, no. 19, Nov. 4, 1920, pp. 878–879. Provision made for sliding scale of payments depending on actual cost of Wanaque water supply project in New Jersey.

CONVEYORS

Marcus Trough. The Use of the Marcus Conveying Trough in Foundries and Other Plants (Ueber die Anwendung der Marcus-Rinne in Giessereien und anderen Betrieben), Wilhelm Venator. Der praktische Maschinen-Konstrukteur, vol. 53, no. 29–30, July 22, 1920, pp. 257–264, 24 figs. Consists of a rigid sheet-iron trough resting on rollers with a uniform acceleration forward and a corresponding retardation on return path. Describes its many useful possibilities and points out that its cost is low in comparison to its practicability and advantages.

CORROSION

Galvanized Iron. Destruction of Galvanized Corrugated Iron through Flue Gases (Zerstörung von verzinktem Eisenwellblech durch Rauchgase), Pb. Siedler. Rauch u. Staub, vol. 10, no. 9–10, June-July, 1920, pp. 43–50, 18 figs. on 6 supp. plates. Based on investigations and literature, it is concluded that the resistivity of galvanized corrugated iron, when used for structures exposed to flue gases containing SO_2 or to flue-dust deposits, is of short duration, and when its employment for this purpose is unavoidable, it is advisable to add a protective coating against rust. Bibliography.

Iron. Corrosion of Iron in Sulphuric Acid. Effect of Chromium Compounds, George W. Heise and Amando Clemente. Philippine Jl. of Sci., vol. 16, no. 5, May 1920, pp. 439–446, 1 fig. Experiments conducted to determine effect of (1) varying concentration of sulphuric acid and of potassium dichromate, and (2) of additions of chromium salts.

Steel. Studies on the Corrosive Action of Chlorine-Treated Water. I—The Effects of Steel on the Equilibrium: $Cl_2 + H_2O \rightleftharpoons HCl + HClO$, and of Products of the Equilibrium of Steel, George L. Clark and R. B. Iseley. Jl. Indus. & Eng. Chem., vol. 12, no. 11, Nov. 1920, pp. 1116–1122. Based on records of corrosion produced by water of various American cities.

Theories of. The Effect of Air and Water on Materials Used in Engineering Work, H. E. Yerbury. Jl. Instn. Elec. Engrs. (Supp.), vol. 57, part 2, Oct. 1920, pp. 118–126 and (discussion) pp. 126–133. Chemical and electrolytic theories of corrosion. Effects on iron and steel and non-ferrous alloys. Instances of damage to metals, etc., subjected to air and water.

COST ACCOUNTING

Machine Shops. Machine Rate Hour in Distributing Expense, Christopher Haigh. Iron Age, vol. 106, no. 19, Nov. 4, 1920, pp. 1207–1208. General advantages of method. (Abstract.) Paper read before Am. Gear Manufacturers' Assn.

Predetermining Needs. When, What and How Much to Buy, Charles W. Dean. Indus. Management, vol. 60, no. 5, Nov. 1920, pp. 362–364, 5 figs. Predetermining raw material needs as function of cost accounting.

CRANES

Electric. 25-Ton Electric Luffing Crane. Eng., vol. 110, no. 2859, Oct. 15, 1920, pp. 501–503, 5 figs. Electric crane fitted with Toplis horizontal luffing gear and balanced jib supplied to Port of London Authority by Stothert & Pitt, Ltd., England.

60-Ton Electric Overhead Traveling Forge Crane. Eng., vol. 110, no. 2861, Oct. 29, 1920, pp. 572–574 and p. 576, 6 figs. Constructed by William Arrol & Co., Ltd., Glasgow. Crane has span of 56 ft. 11 in. and height from floor to rail level of 28 ft. 9 in. With load of 60 tons hoisting motor of 50 b.hp. running at 470 r.p.m. gives lift of 8 ft. per minute.

Floating. Two Hundred-Ton Floating Crane for Liverpool. Engr., vol. 130, no. 3381, Oct. 15, 1920, pp. 375 and 378, 3 figs. Crane lifts weight of 200 tons and hoists up to height of 170 ft. above water line at distance of 110 ft.

Safety Devices. Crane Safety Devices, Nicholas Prakken. Metal Trades, vol. 2, no. 11, Nov. 1920, pp. 453–455, 5 figs. Typical safety devices for cranes used in foundries, machine shops, yards, shipyards and warehouses. Paper read before Nat. Safety Congress.

CRANKSHAFTS

Torsional Vibration. The Critical Speeds of Torsional Vibration, F. M. Lewis. Jl. Soc. Automotive Engrs., vol. 7, no. 5, Nov. 1920, pp. 418–424 and (discussion) pp. 424–431, 14 figs. Mathematical study.

Torsional Vibration and Critical Speeds in Crankshafts, J. F. Fox. Jl. Soc. Automotive Engrs., vol. 7, no. 5, Nov. 1920, pp. 413–417 and p. 435, 14 figs. Vibration chambers constructed to overcome torsional vibration in crankshaft of submarine engine.

CUPOLAS

Slag from. Operating Analysis of Cupola Furnace Slag (Betriebsanalyse der Kupolofenschlacke), Bernhard Osann. Giesserei Zeitung, vol. 17, no. 17, Sept. 1, 1920, pp. 275–276. Notes on the rapid determination of CaO, Mn, Fe, and S contents.

CUTTING METALS

Drilling. Supplement to Frederick W. Taylor's "On the Art of Cutting Metals"—XII, Carl G. Barth. Indus. Management, vol. 60, no. 5, Nov. 1920, pp. 365–372, 14 figs. Writer shows how intelligent study of drill shapes, speeds and feeds may be made to contribute to tool endurance and increased production.

[See also OXY-ACETYLENE CUTTING.]

CYANAMID PROCESS

Action of CO on. Studies on Calcium Cyanamide, Naoto Kameyama. Jl. College of Eng., Tokyo Imperial University, vol. 10, no. 9, Aug. 25, 1920, pp. 309–347, 7 figs. Action of carbon monoxide upon calcium cyanamide.

Heat of Formation. Heat of Combustion and Heat of Formation of Calcium Cyanamide, Naoto Kameyama. Jl. College of Eng., Tokyo Imperial University, vol. 10, no. 10, Aug. 30, 1920, pp. 239–253. Experimental determination.

Preparation. On the Preparation of Cyanamide of Calcium, Naoto Kameyama. Jl. College of Eng., Tokyo Imperial University, vol. 10, no. 8, July 25, 1920, pp. 173–207. Experimental study of chemical reactions, taking urea and dicyandiamide as amides.

CYLINDERS

Cores. Cylinder Cores Made in Green Sand. Foundry, vol. 48, no. 21, Nov. 1, 1920, pp. 861–866, 12 figs. Special machines for cores and molds together with accurately fitting flasks and arbors are outstanding features of process.

D

DAMS

Concrete, Gravity. Construction Features of Snow Mountain Dam. Elec. Rev. (Chicago), vol. 77, no. 19, Nov. 6, 1920, pp. 725–726, 1 fig. Methods used in building gravity concrete dam for impounding storage water for Eel River Hydroelectric Plant of the Snow Mountain Water & Power Co. in California.

Spillways. Spillways for Weir Dams, with Special Consideration of Weir Dams on Alluvial Subsoil (Vor- und Sturzbetten an Stauanlagen mit besonderer Berücksichtigung der Wehranlagen auf angeschwemmtem Untergrunde), G. W. Schmidt. Zeitschrift fur Bauwesen, vol. 70, no. 7–9, 1920, pp. 555–595, 29 figs. Gives rules for planning designs of spillways and similar constructions, and new recommendations.

Tilting. Tilting Dams Applied to Water Works Reservoirs, J. F. Springer. Fire & Water Eng., vol. 68, no. 18, Nov. 3, 1920, pp. 915–917, 5 figs. Description of Baltimore elastic dam with sections that tilt as backwater pressure approaches danger point. Sections open automatically at head at which they are set.

DIES

Embossing. Steelstamps. Embossing Dies. Stencils, Ellworth Sheldon. Am. Mach., vol. 53, no. 18, Oct. 28, 1920, pp. 789–794, 2 figs. Description of processes.

DIESEL ENGINES

Cement Mills. Diesel Engines in Cement Mills. Power, vol. 52, no. 17, Oct. 26, 1920, pp. 655–659, 3 figs. Installation at Iola, Kansas, of Lehigh Portland Cement Co. Engines have proven economical.

Compressorless. Diesel Engines Without Compressors (Ueber kompressorlose Dieselmaschinen), Arthur Balog. Der praktische Maschinen-Konstrukteur, vol. 53, no. 31, Aug. 5, 1920, pp. 282–284, 5 figs. It is claimed that Diesel engines can only become perfect when the spraying compressor is eliminated; an auxiliary compressor should suffice for starting; spraying can be effected with or without aid of spraying medium.

Experiments. British Admiralty Experiments with Diesel Engines—II, C. J. Hawkes. Motorship, vol. 5, no. 11, Nov. 1920, pp. 998–1001, 3 figs. Four-stroke vs. 2-stroke opposed-piston types. (Continuation of serial.)

Fuels for. Fuel for Diesel Engines, C. H. Peabody. Marine Eng., vol. 25, no. 11, Nov. 1920, pp. 915–917. Characteristics of various fuels.

Marine. New Double-Acting, Two-Cycle Marine Diesel-Engine, M. Goldberg. Motorship, vol. 5, no. 11, Nov. 1920, pp. 993–994, 4 figs. American engine of two-cycle double-acting type. Scavenging-air pump between working cylinders.

The Present Position of the Marine Diesel Engines, James Richardson. Eng., vol. 110, no. 2861, Oct. 29, 1920, pp. 589–592, 2 figs. Comparative economy of Diesel engines and steam engines for shipbuilders. Paper read before Instn. Engrs. & Shipbuilding in Scotland.

DRILLING

Rock, Dust Produced. Investigations Made with the Konimeter to Ascertain the Amount of Dust Produced in Drilling Holes by Means of Dry Jack Hammer Machines, H. E. Barrett. Jl. Chem., Metallurgical & Min. Soc. of South Africa, vol. 21, no. 1, July 1920, pp. 1–8.

Rock, Sticking of Steel. Stuck Steel, D. E. Dunn. Eng. & Min. Jl., vol. 110, no. 19, Nov. 6, 1920, pp. 903–905, 8 figs. Reasons for sticking of drill steel.

[See also CUTTING METALS, Drilling.]

DRILLING MACHINES

High-Speed Radial. The New Asquith High-Speed Radial. Machy. (Lond.), vol. 17, no. 419, Oct. 7, 1920, pp. 28–29, 1 fig. Radial drilling machines produced to meet demands for medium-sized high-speed machine to deal with holes of moderate size in work.

DRY KILNS

Superheated Steam. Drying Lumber with Superheated Steam. Forest Products Laboratory, Technical Notes, Oct. 15, 1920, no. 111, 1 p. Superheated steam process has been found applicable to Douglas fir, firs of all kinds, western hemlock, white cedars, sugar pine, western yellow pine and southern yellow pine. Process is unsuited for some softwoods on account of collapse.

Water Spray. Manual for Design and Installation of Forest Service Water Spray Dry Kiln, L. V. Teesdale. U. S. Dept. Agriculture, bul. no. 894, Oct. 18, 1920, 47 pp., 18 figs.

E

ELECTRIC CIRCUITS, A. C.

Current Distribution. A Device for the Rapid Determination of the Current Distribution on the Line Side of a Three-Phase Interconnected-Star Static Balancer Operating on a Four-Wire System S. Austen Stigant. Jl. Instn. Elec. Engrs. (Supp.), vol. 57, part 2, Oct. 1920, pp. 201–208, 5 figs. Device for determining line currents under different loading conditions.

ELECTRIC FURNACES

Booth Rotating. Booth Rotating Electric Furnace, Carl H. Booth. Metal Industry (N.Y.), vol. 18, no. 10, Oct. 1920, pp. 456–459, 3 figs. Description of furnace. Records of operation as obtained in installations ranging in size from 250 lb. to 2000 lb. per heat.

Greaves-Etchells. An Improved Greaves-Etchells Electric Furnace Installation, Edward T. Moore. Chem. and Metallurgical Eng., vol. 23, no. 17, Oct. 27, 1920, pp. 825–832, 21 figs. Description of Greaves-Etchells electric furnace and of arrangement of electrical equipment as installed at plant of Halcomb Steel Co. Records of operation.

Metal-Melting. Application of Electrical Energy to the Melting of Metals, H. A. Greaves. Jl. Instn. Elec. Engrs. (Supp.), vol. 57, part 2, Oct. 1920, pp. 250–253 and (discussion) pp. 276–305, 11 figs. Comparative study of different types of furnaces.

Operating Data. Electric Furnace Operating Data, C. H. Reeder. Eng. World, vol. 17, no. 5, Nov. 1920, pp. 352–355, 4 figs. Present and future prospects of electric furnaces. Figures showing various items of expense involved in melting of steel. Unit costs. Raw materials and finished product.

Refractories for. Electric Furnace Refractories, A. F. Greaves-Walker. Chem. & Metallurgical Eng., vol. 23, no. 19, Nov. 10, 1920, pp. 933–936. Description of raw materials available for highest-grade brick with list showing recommended refractories for melting different metals and alloys, and hints on care, storage and laying of roofs, hearths and linings.

Sahlin. A New Type of Electric Furnace, Axel Sahlin. Jl. Instn. Elec. Engrs., (Supp.), vol. 57, part 2, Oct. 1920, pp. 265–267, 2 figs. Sahlin

furnaces.

Steel Refining. Developments in Electric Iron and Steel Furnaces, J. Bibby. Jl. Instn. Elec. Engrs. (Supp.), vol. 57, part 2, Oct. 1920, pp. 23?–246, 24 figs. Electric reduction furnace and steel refining furnace are taken up.

Large Electric Steel-Melting Furnaces, Victor Stobie. Jl. Instn. Elec. Engrs. (Supp.), vol. 57, part 2, Oct. 1920, pp. 268–276, 9 figs. Furnace requirements of a large steel plant.

United Kingdom. Electric Furnaces in the United Kingdom, 1918, R. G. Mercer. Jl. Instn. Elec. Engrs. (Supp.), vol. 57, part 2, Oct. 1920, pp. 254–264. Records of operation of electric furnaces used in manufacture of steel.

ELECTRIC GENERATORS, A. C.

Slow Speed. 1,750 K. V. A. Slow-Speed Alternator. Eng., vol 110, no. 2857, Oct. 1, 1920, pp. 440–442 and 444, 22 figs. Constructed by General Electric Co., Ltd., Engineers, London. Terminal pressure in tests was 5200 volts between phases and frequency 50 cycles per second at speed of 187.5 r.p.m.

ELECTRIC GENERATORS, D. C.

Axle. Specification for Axle Generators. Ry. Elec. Engr., vol. 11, no. 10, Oct. 1920 pp. 367–370. Specification intended to cover axle-generator equipment for railway service. Committee report of Assn. of Elec. Engrs.

ELECTRIC LAMPS, ARC

Cooper Hewitt. The Cooper Hewitt Lamp—II, L. J. Buttolph. Gen. Elec. Rev., vol. 23, no. 10, Oct. 1920, pp. 858–866, 17 figs. Outlines development and some applications of lamp from 1901 to present time.

ELECTRIC LOCOMOTIVES

Crank Gear, Critical Speeds of. The Critical Speeds of Crank Gears of Electric Locomotives (Die kritischen Drehzahlen der Kurbelgetriebe elektrischer Lokomotiven), W. Kummer. Schweiz. elektrotechnischer Verein Bull., vol. 11, no. 9, Sept. 1920, pp. 237–242, 3 figs. Gives critical numbers of revolutions which can be expected in the case of so-called ideal crank gear; crank gear with deviation of rod lengths from distance of bearing center; and crank gear with play of bearings. It is pointed out that in the construction of large locomotives with parallel crank gears, the occurrence and prevention of critical speeds should be investigated by means of preliminary calculations.

Heavy Electric Traction. Report of the Committee on Heavy Electric Traction. Am. Elec. Ry. Eng. Assn., report no. 305, Oct. 11–15, 1920, 24 pp., 20 figs. Survey of recent developments and progress in design of motors and motor drives for heavy traction, both a.c. and d.c., with comparison of weight, space efficiency, etc.; description and illustrations of recent types of electric locomotives since report of 1916; and comparison of electric switching engines in freight yards with steam engines.

Italian State Railways. Three-Phase Electric Locomotive for the Italian State Railways. Eng., vol. 110, no. 2858, Oct. 8, 1920, pp. 469–471, 22 fig. partly on 4 supp. plates. Details of six three-phase 4-6-4 type electric locomotives built by Construzioni Meccaniche di Saronno of Milan. Working voltage is 3300. Maximum draw-bar pull is 26,000 lb.

Performance. Data on Electric Locomotive Performance. Elec. World, vol. 76, no. 18, Oct. 30, 1920, pp. 878–880, 1 fig. Advantages claimed for electric locomotive are economy of fuel, increased haulage, low maintenance and general flexibility. Graph showing coal consumption comparison on identical runs by steam and electric locomotives is included.

ELECTRIC METERS

Mean Intensity Indicator. Chromothermic Mean Intensity Indicator (Indicateur chromothermique d'intensité moyenne), Ch. Ed. O'Keenan. Revue générale de l'Electricité, vol. 8, no. 15, Oct. 9, 1920, pp. 493–497, 8 figs. A steel needle is heated by passage of current. Current intensity is determined from nature of coloration assumed by needle.

ELECTRIC MOTORS

Railway. The Ventilation of Railway Motors (Beitrag zur Lüftung von Bahnmotoren), W. Dittrich. Elektrische Kraftbetriebe u. Bahnen, vol. 18, no. 13, May 4, 1920, pp. 114–115, 1 fig. Describes air vane designed by author in which the air enters motor on the ventilator side and passes out on the commutator side, carrying off carbon dust which otherwise would settle on windings.

Standardization. Motor Features Requiring Standardization, C. W. Starker. Elec. World, vol. 76, no. 19, Nov. 6, 1920, pp. 919–921, 5 figs. Urges standardization of mechanical features of electrical motors.

ELECTRIC MOTORS, D. C.

Crane and Hoist Drive. Direct-Current Motors for Crane and Hoist Work, F. L. Moon. Elec. Jl., vol. 17, no. 11, Nov. 1920, pp. 532–535, 7 figs. Graphs showing comparative characteristics of enclosed and ventilated motors.

Reversing Pole. The Calculation of the Reversing Pole in Direct-Current Motors (Zur Berechnung der Wendepole bei Gleichstrommaschinen), Wilhelm Oelschläger. Elektrotechnik u. Maschinenbau, vol. 38, no. 23, June 6, 1920, pp. 261–266, 7 figs. For-

Starters. New Motor Starter Embodies Many Interesting Features. Power Plant Eng., vol. 24, no. 22, Nov. 15, 1920, pp. 1075–1076, 2 figs. Automatic starter designed for general use in controlling series, shunt and compound-wound direct-current motors employed to drive pumps, line-shafts, compressors, blowers, conveyors, etc.

ELECTRIC PLANTS

Inspection. Scheduled Inspection for Power Plants. Elec. World, vol. 76, no. 19, Nov. 6, 1920, pp. 922–924, 2 figs. Forms for keeping records.

Interconnection. Interconnection of Power Systems, Harold W. Smith. Elec. Jl., vol. 17, no. 11, Nov. 1920, pp. 515–518, 4 figs. Comparative study of the various method of interconnecting generating stations.

Remote Control. Remote Control in Three-Phase Plants (Fernsteuerung in Drehstromanlagen), H. Roth. Elektrotechnische Zeitschrift, vol. 41, no. 35, Sept. 2, 1920, pp. 685–686, 6 figs. Describes system for three-phase plants which permits, without special switch lines, the selective connection or disconnection of a large number of switches, in which use is made of a split-up direct-current superposed on the three-phase current, making use of the resonance between this direct current and the natural vibration of a small direct-current armature serving as a receiver.

ELECTRIC RAILWAYS

Buildings and Structures. Report of the Committee on Buildings and Structures. Am. Elec. Ry. Eng. Assn., report no. 309, Oct. 11–15, 1920, 17 pp., 7 figs. Inspection and maintenance of buildings and structures; lag screws vs. bolts in timber-decked structures; prepayment and postpayment collection of fares at terminals; review of existing standards and recommendations.

Current Standardization. Problems of the Electric Railway, G. Wüthrich. Engr., vol. 130, no. 3377, Sept. 17, 1920, pp. 281–283, 1 fig. It is argued that extra high-tension low periodicity single-phase current system is alone capable of lending itself to immediate and simultaneous standardization for both suburban and main line traction.

Diesel-Electric Motor Cars. Diesel-Electric Motor Cars of the Swedish Railways (Automotrices pétroléo-électriques à moteur Diesel des chemins de fer suedois). Génie Civil, vol. 77, no. 16, Oct. 16, 1920, pp. 305–309, 16 figs. Used in local railways.

Equipment. Report of the Committee on Equipment. Am. Elec. Ry. Eng. Assn., report no. 311, Oct. 11–15, 1920, 39 pp., 33 figs. Standards for brakeshoes, brakeshoe heads, and brakeshoe keys; feasibility of adopting standard cars.

Power Distribution. Report of the Committee on Power Distribution. Am. Elec. Ry. Eng. Assn., report no. 304, Oct. 11–15, 1920, 100 pp., 7 figs. Specifications for overhead line material, electric light, power supply, trolley lines crossing steam and electric railroads, standard thread for pins and insulators, etc.

Power Generation. Report of the Committee on Power Generation. Am. Elec. Ry. Eng. Assn., report no. 308, Oct. 11–15, 1920, 60 pp., 5 figs. Recommended form of power contract for purchase of power; comparative cost of steam production for utilization in electric power plants from using coal, oil, gas or other special fuels; tabulation of costs of power generated by member companies.

Speed-Time Curves. Note on the Drawing of the Speed-Time Curves of Electric Trains, J. Musyck. Bul. Int. Ry. Assn., vol. 2, no. 9, Sept. 1920, pp. 581–590, 7 figs. Graphical method.

Trolley Contact Voltage. What Happens at the Trolley Contact? D. D. Ewing. Elec. Ry. Jl., vol. 56, no. 17, Oct. 23, 1920, pp. 863–865, 3 figs. Results of tests under various operating conditions. Contact voltage graphs for various types of wheels are shown. Average power loss with 5-in. wheel was nearly 1/2 kw.

ELECTRIC RAILWAYS, TRACK

Circuiting. Alternating-Current Track Circuiting, L. H. Peter. Jl. Instn. Elec. Engrs., vol. 58, no. 292, June 1920, pp. 491–506, 30 figs. Distinction is made between "in phase" and "quadrature" relays, vector diagrams are given of track circuit without impedance bonds and phase displacement is obtained with two types of relays. Vector diagrams of track circuit with non-resonated and with resonated impedance bonds are also constructed. Method of varying the relay track-winding power factor is given and effect on vector diagram discussed.

Insulated Tools. Insulated Tools for Use on the Permanent Way of Electrified Railways. Ry. Gaz., vol. 33, no. 17, Oct. 22, 1920, pp. 541, 2 figs. Newly designed insulated tools, patented and manufactured by British Power Railway Signaling Co.

Track Welding. See ELECTRIC WELDING, Rails.

Trackwork Specifications. Report of the Committee on Way Matters. Am. Elec. Ry. Eng. Assn., report no. 310, Oct. 11–15, 1920, 95 pp., 13 figs. Recommended specifications for track spirals; standard sections for curved-head rails; revision of specifications for plain bolted special trackwork; specifications for wood-block paving; compilation of data on safe limits of wear in rails and special trackwork on life of track construction of various types.

Comparative study of characteristics of various types.

High-Voltage. Notes on the Electrical Calculations of Long-Distance High-Voltage Transmission Lines, A. McKinstry. Jl. Instn. Elec. Engrs. (Supp.), vol. 57, part 2, Oct. 1920, pp. 92–117, 8 figs. Fundamental formulæ for transmission lines without branches. Study of constant voltage transmission.

Lightning Protection. See LIGHTNING ARRESTERS.

Long-Distance. Calculation, Diagrams and Regulation of Long Distance Electric Transmission Lines (Calculs, diagrammes et regulation des lignes de transport d'énergie à longue distance), L. Theilemans. Revue générale de l'Electricité, vol. 8, nos. 13, 14 and 15, Sept. 25 and Oct. 2 and 9, 1920, pp. 403–416, 435–443 and 475–482, 39 figs. Methods employed by writer in his practice as engineer of French Thomson-Houston Co. (To be continued.)

Switching and Protection. Switching and Protection of Transmission Circuits—III, S. Q. Hayes. Elec. Jl., vol. 17, no. 11, Nov. 1920, pp. 521–526, 7 figs. Exemplifies manner of proceeding by determining switching equipment needed in case of generating station containing fifteen 25,000-kva. vertical-shaft waterwheel generators.

Size of Wire. Determining Size of Wire and the Length of Span, D. F. Parrott. Elec. World, vol. 76, no. 19, Nov. 6, 1920, p. 928. No. 6 wire and 250-ft. span are said to be found economical for most cases where voltage lies between 33,000 and 66,000.

ELECTRIC WELDING

Methods. Electric Welding, Fred H. Williams. Jl. Eng. Inst. Canada, vol. 3, no. 11, Nov. 1920, pp. 514–522, 12 figs. History and survey of electric welding methods. Account of research work by writer.

Rails. Method of Preheating and Reheating of Workpieces in Electric Arc Welding or Autogenous Welding Work (Verfahren zum vor und nachwärmen von Werkstücken bei elektrischer Lichtbogenschweissung oder autogener Schweissung). Autogene Metallbearbeitung, vol. 13, no. 14, July 15, 1920, pp. 162–163. Details of process patented by the Accumulator Works Corp., Berlin, said to be of special value for the electric welding of rails.

ELECTRIC WELDING, ARC

Effect on Eye. Effect of Ultra-Violet Rays on the Eye, C. R. Kindall. Reports of Investigations, Bur. of Mines, Dept. of Interior, serial no. 2173, Oct. 1920, 2 pp. Records of effect on eye of electric arc welding.

ELECTRIC WELDING, RESISTANCE

Spot-Welding Machines. Modern Welding and Cutting—XXXI, Ethan Viall. Am. Mach., vol. 53, no. 18, Oct. 28, 1920, pp. 807–821, 39 figs. Spot-welding machines.

ELECTRICAL MACHINERY

Windings. The Maximum Temperature for Windings (Höchsttemperatur an Wicklungen), Kurt Lubowsky. Elektrotechnische Zeitschrift, vol. 41, no. 33, Aug. 19, 1920, pp. 646–647, 2 figs. The Vidmar formula for determination of maximum temperature from the mean and minimum temperature is tested on a long high-voltage stator coil, and results coincide with the observation of Rogowski and Vieweg on round coils according to which the minimum temperature should be measured directly on the conductors. It is concluded that the practicability of formula is limited.

ELECTRICAL SYMBOLS

International Standards. Electrical Symbols Proposed for International Adoption. Elec. World, vol. 76, no. 20, Nov. 13, 1920, pp. 971–972. Complete set adopted by Advisory Committee for consideration of next plenary meeting of international electrotechnical commission.

ELECTRICITY

World's Supply. Development of Rural Electricity Supply. Elecn., vol. 85, no. 2214, Oct. 22, 1920, pp. 472–475, 4 figs. Scheme of rural electricity supply in Hereford, England, a city of 22,000 inhabitants, which is center for commercial side of agricultural trade of surrounding district. Electricity is supplied to surrounding country from municipally owned station.

ELECTRON TUBES

Tungsten-Filament. Some Practical Operating Features of Tungsten Filament Electron Tubes, W. C. White. Gen. Elec. Rev., vol. 23, no. 10, Oct. 1920, pp. 840–846, 2 figs. Curves showing electron emission per watt of energy used to heat pliotron filament.

EMPLOYMENT MANAGEMENT

Bibliography. A Guide and Bibliography for Labor Managers, Leverett S. Lyon and May R. Freedman. Indus. Management, vol. 60, no. 5, Nov. 1920, pp. 383–385.

Interviewing Workers. The Art of Interviewing Workers, J. D. Hackett. Indus. Management, vol. 60, no. 5, Nov. 1920, pp. 338–340. Qualifications necessary in an interviewer, and essential steps in interviewing.

Vocational Classification of Employees. Making it Easy to Find the Right Technical Men, I. W.

ENGINEERING INDEX (Continued)

Litchfield. Factory, vol. 25, no. 8, Oct. 15, 1920, pp. 1232–1234, 2 figs. Suggests methods of classifying employees by industry and by function.

EMPLOYEES' REPRESENTATION

Shop Committees. The Operation of the Whitley Councils. Metal Industry (N. Y.), vol. 18, no. 10, Oct. 1920, p. 470. History, development and present state of England's experiment in coöperation between employer and employee. (Concluded.)

Workmen's Representation in a Tool Manufacturing Plant. Machy. (Lond.), vol. 17, no. 422, Oct. 28, 1920, pp. 111–115, 1 fig. Shop committee plan of Greenfield Tap & Die Corp. which operates six plants in U. S.

ENGINEERING SOCIETIES

The Federated American Engineering Societies. The Engineering Educator's Opportunity in Engineering Organization, William E. Bullock. Eng. Education, Bul. Soc. Promotion of Eng. Education, vol. 11, no. 2, Oct. 1920, pp. 72–75. Scheme of organization of engineering profession by means of Federated American Engineering Societies is explained. Plan of federation contemplates formation of all-inclusive local societies of engineers in important communities and their organization into federation for action on matters dealing with public service.

ENGINEERS

Fees and Salaries. Recommended Salaries for Manitoba Engineers. Contract Rec., vol. 34, no. 44, Nov. 3, 1920, pp. 1046–1047. Report on remuneration of engineers submitted by Salary Committee of Manitoba Branch of Engineering Institute of Canada.

Various Schedules of Fees for Consulting Engineers, Edmund I. Mitchell. Eng. News-Rec., vol. 85, no. 20, Nov. 11, 1920, pp. 941–942. Compiled by Edmund I. Mitchell, Assistant Secretary of Committee on Classification and Compensation of Engineers, Engineering Council, New York City, with aid of Engineering Societies' Library.

Registration. Report of Committee to the Minnesota Joint Engineering Board-Recommended Registration Law. Bul. Affiliated Eng. Soc. of Minnesota, vol. 5, no. 10, Oct. 1920, pp. 18–26. Suggested text of act to regulate practice of architecture, professional engineering and land surveying in Minnesota.

EXCAVATION, EARTH

See SHOVELS, Rotary.

EXCAVATORS

Development of. Recent Excavator Practice, F. H. Livens and W. Barnes. Jl. Instn. Mech. Engrs., no. 6, Oct. 1920, pp. 609–630 and (discussion) pp. 631–637, 16 figs. Survey of progress in development of types, with special reference to the steam-navvy.

Dragline. Storm Sewer Construction with a Dragline Excavator. Excavating Engr., vol. 14, no. 9, Nov. 1920, pp. 295–296. Description of excavation of large storm sewer in Detroit with dragline excavator. Method of handling forms.

EXPLOSIVES

Explosion Point, Determination of. Apparatus for the Safe Determination of the Decomposition or Explosion Point of Explosive Substances (Apparat zur gefahrlosen Bestimmung des Zersetzungs- oder Verpuffungspunktes explosiver Substanzen), A. Langhans. Zeit. für das gesamte Schiess- u. Sprengstoffwesen, vol. 15, no. 15, Aug. 1, 1920, pp. 161–163, 2 figs. Points out that the Wood metal bath usually employed for this purpose has the disadvantage that with the explosion of the substance a part of the melted, red-hot metal is hurled out, whereby either accidents occur to the investigators, or apparatus is soiled; and describes new apparatus with lead or aluminum blocks, designed to mitigate this danger.

EXPORT TRADE

Statistics. Export and Import Statistics Indicate Industrial Trend. O. M. Fox. Eng. News-Rec., vol. 85, no. 18, Oct. 28, 1920, pp. 835–836, 1 fig. It is concluded from survey of figures, that imports are rapidly increasing to a point where United States will no longer occupy a favorable trade position.

F

FACTORY MANAGEMENT

See INDUSTRIAL MANAGEMENT.

FARM MACHINERY

Improvements in. Agricultural Machinery, Gustav Fischer. Eng. Progress, vol. 1, no. 10, Oct. 1920, pp. 301–304, 9 figs. Improvements in thrashing machines, straw presses, chaff cutter and bruising mills.

FATIGUE

Industrial. The Speed of Adaptation of Output to Altered Hours of Work, H. M. Vernon. Eng. and Indus. Management, vol. 4, no. 15, Oct. 7, 1920, pp. 450–451. Data on evidence obtained at British munition factories during war. (Abstract.) Report of British Industrial Fatigue Research Board.

FILTRATION PLANTS

Operation. Filter Underdrain, Sand-Bed and Wash-water Experience. Eng. News-Rec., vol. 85, no. 20, Nov. 11, 1920, pp. 934–939. Symposium on current practice and operating success with various details of mechanical or rapid water filtration plants. (To be continued.)

FIRE BOATS

Diesel-Electric vs. Steam. Diesel-Electric Propulsion Versus Steam for Fire-Boats, William H. Easton. Motorship, vol. 5, no. 11, Nov. 1920, p. 997. Diesel electric is found more advantageous.

FIRE PROTECTION

Fire-Alarm Stations. A Central Fire-Alarm Station, C. W. Geiger. Jl. Electricity, vol. 45, no. 9, Nov. 1, 1920, pp. 432–434. San Francisco station.

Underwriters' Laboratories. Underwriters' Laboratories' Protection Department, W. C. Robinson. Nat. Fire Protection Assn., vol. 14, no. 2, Oct. 1920, pp. 141–145. Survey of work of protection Department of Underwriters' Laboratories.

FLIGHT

Soaring. Mechanical Equivalents of Soaring Flight. English Mechanic, vol. 112, no. 2902, Nov. 5, 1920, pp. 172–173. Circular tea-tray with deep rim in which heavy ball is rolled rapidly, motion being kept going by working tea-tray round in small circle. Ball's going round over tray is analogous to bird's gliding round at steady headway through air, friction force opposing bird corresponding to head resistance of opposing bird, and circular movement of tray corresponding to centrifugal propulsive force arising from small circular movement of air.

FLOW OF FLUIDS

Pipe Lines. Effect of Fittings on Flow of Fluids Through Pipe Lines, E. Foster. Mech. Eng., vol. 42, no. 11, Nov. 1920, pp. 616–618, 11 figs. Graphical solution of Babcock's formula for flow of steam in pipe lines. Tables giving equivalent lengths of standard pipe to allow for various screw fittings in conduits carrying non-viscous liquids, steam, air or gas.

FLOW OF WATER

Drain Tiles. New Formula for Flow of Water in Drain Tile. Eng. and Contracting, vol. 54, no. 15, Oct. 13, 1920, pp. 374–375, 1 fig. Formula derived from experiments in which 824 separate tests were made. From Bulletin 854 of U. S. Dept. of Agriculture.

Manning's Formula. Charts for Solution of Manning's Hydraulic Formula, Elmo G. Harris. Eng. News-Rec., vol. 85, no. 18, Oct. 28, 1920, pp. 837–839, 2 figs.

Theory of. On a Theory of Fluid Friction and Its Application to Hydraulics, E. Parry. English Elec. Jl., vol. 1, no. 4, Oct. 1920, pp. 146–164, 4 figs. Generalization of theory of fluid friction employed in aeronautics to flow of water in pipes and conduits. Table giving values of coefficient in Chézy's formula for flow of water in pipes and conduits.

FOREIGN TRADE

Prospects for. Prospects for Foreign Trade, A. H. Holliday. Iron Age, vol. 106, no. 18, Oct. 28, 1920, pp. 1106–1107. Statistics show loss of steel production to peaceful arts during war. (Abstract.) Paper read before Am. Iron & Steel Inst.

FORGING

Recording Apparatus. The Solution of Forging Problems, Eugene Schneider. Eng. & Industrial Management, vol. 4, no. 17, Oct. 21, 1920, pp. 520–525, 2 figs. Schneider apparatus for recording times and pressures employed during forging in relation to the stroke.

FOUNDRIES

Accidents in. See ACCIDENTS, Foundries.

Brass. Reclamation of Metal from Brass-Foundry Refuse, F. L. Wolf and G. E. Alderson. Metal Industry (N.Y.), vol. 18, no. 10, Oct. 1920, pp. 452–455, 2 figs. Records of costs and returns obtained in reclaiming plant used at Ohio Brass Co. Paper read before Inst. of Metals Division.

See also RAILWAY SHOPS, Brass Castings for.

British. English Foundry Makes Rail Chairs, H. Cole Estep. Foundry, vol. 48, no. 18, Sept. 15, 1920, pp. 733–740, 13 figs. Quantity production methods employed. Molds are made on roll-over, stripping-plate machines of special design; cupolas melt continuously.

Scrap Utilization in. Utilization of Scrap from Iron and Steel Foundries, with Special Regard to the Recovery of Scrap Iron from Rubbish (Die Verwertung von Abfällen aus Eisen- und Stahlgiessereien insbesondere die Rückgewinnung des Abfalleisens aus dem Schutt), Hubert Hermanns. Dinglers polytechnisches Jl., vol. 335, no. 17, Aug. 21, 1920, pp. 185–188, 7 figs. Notes on the electromagnetic separation of rubbish for the recovery of iron, conditions for which are said to be most favorable in plants where low-voltage direct-current is available as the magnets can be excited only with direct-current. Details of different construction types.

U. S. and Canada. Growth Marks Reconstruction Era. Foundry, vol. 48, no. 21, Nov. 1, 1920, pp. 853–858, 7 figs. List of foundries in United State and Canada in 1920 and 1918 by States and Provinces.

FUELS

Coal vs. Oil. See COAL, Oil vs.

Diesel-Engine. See DIESEL ENGINES, Fuels.

Purchasing of. Premiums for Dry Fuel (Prämien für trockenen Brennstoff), G. Höhn. Zeit. des Bayerischen Revisions-Vereins, vol. 24, no. 16, Aug. 31, 1920, pp. 125–128, 2 figs. A formula is derived and recommended for calculating gain in value of fuel delivered to purchaser in dryer condition than agreed upon, or loss in value when delivered in more moist condition.

FURNACES, BOILER

Forced Draft. Draft Regulation in Forced-Draft Boiler Furnaces (Windregelung bei Unterwindfeuerungen), H. Pradel. Zeit für Dampfkessel u. Maschinenbetrieb, vol. 43, no. 36, Sept. 3, 1920, pp. 273–275, 5 figs. Details of air-current regulator developed by German Evaporator Co., Ltd., by means of which air admitted into every chamber can be regulated.

FURNACES, ELECTRIC

See ELECTRIC FURNACES.

FURNACES, HEAT-TREATING

Insulation. The Function of Insulation and its Application to Heat Treating Furnaces, E. F. Davis. Trans. Am. Soc. for Steel Treating, vol. 1, no. 1, Oct. 1920, pp. 33–42, 4 figs. Formulæ and graph for designing insulation.

FURNACES, OPEN-HEARTH

Efficiency. Increased Efficiency in the Open Hearth, Philip C. Gunion. Blast Furnace & Steel Plant, vol. 8, no. 11, Nov. 1920, pp. 624–625, and p. 635, 3 figs. Effect roller bearings applied to rolling stock has upon reducing transportation costs. Comparative tests made with cars of plain bearing type.

Port Design. Design of Ports for Open Hearth Furnaces, Herbert F. Miller, Jr., Blast Furnace & Steel Plant, vol. 8, no. 11, Nov. 1920, pp. 612–614, 3 figs. Circular water cooled ports used by Lackawanna Steel Co.

G

GAGES

Laboratory Standards. Sizes of the N. P. L. End Standards in English Units. Eng. vol. 110, no. 2858, Oct. 8, 1920, p. 474. Changes which have been made in accepted sizes of laboratory end standards at National Physical Laboratory, England.

Lapping. See LAPPING.

Precision. Precision Gages, M. E. Kanek. Am. Mach., vol. 53, no. 20, Nov. 11, 1920, pp. 884–886. Methods of accurate measurement, and methods of manufacturing precision gages.

Precision Measuring and Inspection Devices—II, R. J. Whibley. Machy. (N.Y.), vol. 27, no. 3, Nov. 1920, pp. 242–245, 6 figs. Minimeter and gage comparator used by National Physical Laboratory, England, for inspecting precision gage-blocks. Devices permit readings to accuracy of one millionth of an inch.

Thread. Adjustable Thread Snap Gauge. Eng., vol. 110, no. 2860, Oct. 22, 1920, pp. 551, 3 figs. Constructed by Coventry Gauge & Tool Co., Ltd., Engineers, Coventry.

GARBAGE DISPOSAL

Methods. Transportation of Garbage with Data on Garbage Disposal in Various Cities, Samuel A. Greeley. Mun. & County Eng., vol. 59, no. 4, Oct. 1920, pp. 132–134. Tables showing method of garbage disposal in 50 of largest cities in U. S.

GAS MAINS

Steel vs. Cast Iron. Steel Versus Cast-Iron for Gas Mains, B. R. Parkinson and Norton H. Humphrys. Gas World, vol. 73, no. 1891, Oct. 16, 1920, pp. 299–300. Opinions of representative engineers.

GAS MANUFACTURE

Regulations in France. New Regulations for the Quality of Illuminating Gas, and New Methods of Manufacture (Nouvelles règles fixant les qualités exigées du gaz d'éclairage, et nouvelles méthodes de fabrication), P. Lauriol. Génie Civil, vol. 77, no. 17, Oct. 23, 1920, pp. 328–329. Suppression of tests of illuminating power and permission to add water gas.

GAS MASKS

Uses in Mines. Danger in Using Army Gas Masks in Mines, George S. Rice. Reports of investigations, Bur. of Mines, Dept. of Interior, serial no. 2175, Oct. 1920, 2 pp. Instances of failure of army gas mask.

GAS PRODUCERS

German. Modern Development of Fuel Gasification, Hubert Hermanns. Blast Furnace & Steel Plant, vol. 8, no. 11, Nov. 1920, pp. 617–624, 13 figs. Development of modern gas producers in Germany. Operation of producer and processes by which complete utilization of all constituents are obtained.

Tar Recovery. Gas-Producer Plants Equipped for Recovery of Low-Temperature Tar (Die Gaserzeugungsanlagen mit Gewinnung von Urteer), E. Roser. Zeit. des Vereines deutscher Ingenieure, vol. 64, no. 42, Oct. 16, 1920, pp. 857–864, 8 figs. Account of tests carried out by the Thyssen & Co. Machine Factory in Mülheim during years 1916–1918. Notes on yield of by-products; determination of extraction of heat from coal; utilization of by-products; future possibilities of process; the use of cold gas in foundry furnaces and in the generation of power; increase in consumption of coal through recovery of by-products.

deg. cent., W. A. Felsing, H. Odeen and C. B. Petersen. Jl. Indus. & Eng. Chem., vol. 12, no. 11, Nov. 1920, pp. 1063–1065, 4 figs. It was found that decomposition of both process A (original 60 deg.-cent. process) and process B (Levinstein) mustard gas takes place in steel shell at 60 deg. cent., but extent of decomposition is not serious even under severe conditions.

The Precipitation of Sulfur from Crude Mustard Gas by Means of Ammonia, W. A. Felsing and S. B. Arenson. Jl. Indus. & Eng. Chem., vol. 12, no. 11, Nov. 1920, pp. 1065–1066. Addition of moist ammonia caused precipitation of about 40 to 45 per cent of total supposedly free sulphur.

Repelling Poisonous Gases. Repelling Poisonous Gases. Sci. Am. Monthly, vol. 2, no. 3, Nov. 1920, pp. 235–236. Fanning system that was used to clear trenches after gas attack.

GAS WORKS

Motive Power. Notes on Operating a By-Product Producer Gas Plant for Power and Heating, W. H. Patchell. Jl. Instn. Elec. Engrs., vol. 58, no. 292, June 1920, pp. 417–430 and (discussion) pp. 437–463, 4 figs. Extension of gas works of Hoffmann Manufacturing Co., Ltd., England.

Waste Disposal. Disposal of Waste from Gas Plants. Am. Gas Eng. Jl., vol. 113, no. 19, Nov. 6, 1920, pp. 363–366. Report of American Gas Association 1920 Committee.

GASOLINE

Alcogas Fuel vs. Comparison of Alcogas Aviation Fuel with Export Aviation Gasoline, V. R. Gage, S. W. Sparrow and D. R. Harper, 3d. Nat. Advisory Committee for Aeronautics, report no. 89, 1920, 14 pp. 47 figs. Tests showed at 5.6 compression the same maximum power production at ground level and general average of 4 per cent more power at altitude for alcogas, maximum difference being about 6 per cent at 6400 ft. and 1800 r.p.m. At 7.2 compression alcogas showed average and fairly uniform increase of 4 per cent in power at altitude.

Carburation of. The Carburation of Gasoline, O. C. Berry and C. S. Kegerreis. Purdue University, Publications of Eng. Depts., vol. 4, no. 1, April 1920, 223 pp., 103 figs. Results of tests carried out to determine richness of fuel to air mixture required by engine under different running conditions in order that it may develop either maximum power or maximum efficiency.

Cracking Manufacturing Practice. Gasoline Cracking Processes, Fred W. Padgett. Chem. & Metallurgical Eng., vol. 23, no. 19, Nov. 10, 1920, pp. 908–913. Description of commercial methods for production of gasoline by pyrolytic distillation of heavy hydrocarbons, including Burton, Greenstreet, Hall, Rittman, Aluminum Chloride, Dubbs, Jenkins, and Bacon processes. List of inventors, patent numbers and dates.

GASOLINE ENGINES

Horsepower Diagram. Diagram to Determine Horsepower of Gasoline Engines, C. E. Lounsberg. Eng. News-Rec., vol. 85, no. 19, Nov. 4, 1920, pp. 892–893, 1 fig. It is held that Swedish formula is best for purpose.

GASOMETERS

Wind Pressure on. The Effect of Wind Forces on Gasometers. (Windkräfte auf Gasbehälter). Jl. für Gasbeleuchtung u. Wasserversorgung, vol. 63, no. 35, Aug. 28, 1920, pp. 566–567, 3 figs. It is concluded that distribution of pressure on smooth model without limitation of bottom cannot be wholly accepted for actual practice; the total resistance of air on an actual gasometer has probably a different value from that resulting from calculation with the coefficient of a model.

GEARS

Automobile. Fixtures for Testing Automobile Gears. Machy. (N. Y.), vol. 27, no. 3, Nov. 1920, pp. 270–273, 8 figs. Methods used at various plants.

Teeth in Contact. Derivation of a Formula to Determine Number of Teeth in Contact of Two Meshing Gears, A. B. Cox. Am. Mach., vol. 53, no. 20, Nov. 11, 1920, pp. 899–902, 10 figs. Formula is derived and graphic representations of results of application of this formula are shown.

GIRDERS

Design. The Stresses in Portals and Similar Structures, Talbot C. Broom. Engr., vol. 130, nos. 3381 and 3382, Oct. 15 and 22, 1920, pp. 368–369, 5 figs., and 393–394, 5 figs. Suggests simplification in design of continuous girders.

GLASS

Expansion at High Temperatures. The Expansion of Glass at High Temperatures, W. B. Pietenpol. Chem. & Metallurgical Eng., vol. 23, no. 18, Nov. 3, 1920, pp. 876–877, 1 fig. Thermal expansion curves of unannealed light barium crown glass.

GOLD METALLURGY

Recovery from Black Sand Tailings. Recovery of Gold from Black Sand Tailings, John Gross. Reports of Investigations, Bur. of Mines, Dept. of Interior, serial no. 2170, Oct. 1920, 2 pp. Tests conducted at Alaska station of Bur. of Mines.

GOLD MINING

Southern U.S. Gold Mining in the Southern States,

GRINDING

Automobile Parts. Cadillac Grinding Practice. Machy. (Lond.), vol. 17, no. 420, Oct. 14, 1920, pp. 33–37, 9 figs. Methods employed in grinding department of plant building Cadillac cars.

GRINDING MACHINES

High-Speed. Grinding at Speed of 100,000 Revolutions per Minute. Can. Machy., vol. 24, no. 16, Oct. 14, 1920, p. 365. Editorial comment on machine produced by British manufacturer which is said to be capable of running safely at 100,000 r.p.m.

H

HARBOR IMPROVEMENTS

Dutch Indies. The Use of Reinforced Concrete for Harbor Construction in the Dutch Indies (Verwendung von bewehrten Beton zu Hafenbauten in Niederländisch-Indien), A. v. Horn. Zentralblatt der Bauverwaltung, vol. 40, no. 72, Sept. 8, 1920, pp. 453–455, 10 figs. Describes extended use of reinforced concrete for piles, caissons for quay walls, storage sheds, loading wharves, etc., including notes abstracted from paper on the technical problems of Indian harbor construction by Wouter Cool (de Ingenieur, no. 8, 1919).

HARMONICS

Analysis. A Practical Method of Harmonic Analysis, Philip Kemp. Jl. Instn. Elec. Engrs. (Supplement), vol. 57, part 2, Oct. 1920, pp. 85–91. Schedule for routine work in analysis of periodic wave forms.

HEAT TRANSMISSION

Radiation. Radiation and Convection from Heated Surface, T. Barratt and A. J. Scott. Physical Soc. of London, Proc., vol. 32, part 5, Aug. 15, 1920, pp. 361–373, 2 figs. Experimental determination was made of amounts of natural convection and radiation from cylindrical and spherical surfaces heated in air at atmospheric temperature and pressure to temperature of about 100 deg. cent. Convection alone was found to be inversely proportional to square root of diameter of cylinder and to cube root of diameter of sphere.

HEATING AND VENTILATION

Humidity Regulator. An Automatic Humidity Regulator (Der selbsttätige Luftfeuchtigkeitsregler "Humidostat"). Gesundheits-Ingenieur, vol. 43, no. 26, June 26, 1920, pp. 306–307, 6 figs. Describes humidostat constructed by the Automatic Temperature Regulation Co., Ltd., Berlin-Friedenau, in which the compressor generates the necessary compressed air and operates in such a manner that when temperature corresponding to 1 atm. above pressure is reached, the movement of compressor ceases and is automatically resumed at lower atmospheric pressure. Points out its many useful possibilities.

Psychrometric Chart. Psychrometric Chart, E. V. Hill. Heating and Vent. Mag., vol. 17, no. 10, Oct. 1920, pp. 50–51, 1 fig. Issued by Chicago Department of Health.

Schools. New Heating and Ventilating System Adopted for Chicago Schools—I. Domestic Eng., vol. 93, nos. 6 and 7, Nov. 6 and 13, 1920, pp. 251–253, 3 figs, and 300–302, 14 figs. Plan recently evolved by chief engineer of Chicago Board of Education.

HEAVY-OIL ENGINES

Reciprocating Parts for. Reciprocating Engine Crosshead Design Applied to Heavy Oil Engines, W. D. Forbes. Marine Eng., vol. 25, no. 11, Nov. 1920, pp. 924–925. Service requirements.

HOBS

Worm-Wheel, Standardization of. Standardization of Worm-Wheel Hobs (Ueber die Normung von Schneckenradfräsern), Fr. Woltzendorff. Betrieb, vol. 2, no. 14, Aug. 1920, pp. 347–352, 6 figs. Advantages of standardization are said to be that the cutters can be fabricated in quantities, are cheaper, more accurate in pitch and boring and interchangeable; worms can be forged and cut in quantities, thus effecting a great saving in time and labor.

HOISTING ENGINES

Standardization. Standardization of Hoisting Machines (Normung von Hebezeugen), Karl Engel. Betrieb, vol. 2, no. 16, Sept. 1920, pp. 417–420. Points out its great advantages from economic standpoint and makes recommendations for calibrated load and hand chains and for gage dimensions.

The Standardization of Hoisting Machines (Die Vereinheitlichung der Hebemaschinen), Leopold Feigl. Betrieb., vol. 2, no. 14, Aug. 1920, pp. 377–380. Discusses program submitted by working committee for standardization of hoisting machines of the N D I, and offers suggestions for extending limits in some cases. Recommendations for standardization of trestle bridges and electrically driven traveling crabs.

HOSE

Steam. Steam Hose Construction, John M. Bierer. India-Rubber Jl., vol. 60, no. 15, Oct. 9, 1920, pp. 9–10. Results obtained from tests by B. F. Goodrich Co. Hose constructed according to different processes were compared.

10. and (discussion), pp. 470–490. Cost figures for electrical equipment supply to houses erected under British Government Housing scheme.

HOUSES, CONCRETE

Construction. Concrete Cottage Building. Concrete and Constructional Eng., vol. 15, no. 10, Oct. 1920, pp. 668–673, 7 figs. Patent system of construction approved by British Ministry of Health.

HOUSING

England. English Efforts to Solve the Housing Problem since the War (Englische Bestrebungen zur Behebung der Wohungsnot nach dem Kriege), Stephan Prager. Zeitschrift für Bauwesen, vol. 70, no. 7–9, 1920, pp. 414–499, 87 figs. Notes on government board for building aid; work of government in overcoming the housing shortage; temporary relief measures through use of barracks, framework buildings and rebuilding of single-family houses into renting apartments; building costs, and material and labor supply; recommendations for substitute building materials and new building methods; success up to present time of the housing policy and future prospects. Bibliography.

France. Low-Priced Houses (La construction d'habitations à bon marché), Paul Razous. Génie Civil, vol. 77, no. 16, Oct. 16, 1920, pp. 309–313. Housing projects for Paris and suburbs.

HUMIDITY

See HEATING AND VENTILATION, Humidity Regulator; Psychrometric Chart.

HYDROELECTRIC PLANTS

New Brunswick, Canada. Hydro-Electric Power Development in New Brunswick, C. O. Foss. Jl Eng. Inst. Canada, vol. 3, no. 11, Nov. 1920, pp. 522–525. Outlines work at Musquash River and Shogomac developments.

Niagara Falls Power Development. Clearing House for Five Stations, J. Allen Johnson. Elec. World, vol. 76, no. 20, Nov. 13, 1920, pp. 961–965, 12 figs. Semi-outdoor substation of Niagara Falls Power Co. Combined output of installations is rated at 400,000 hp.

Norway. Vamma Hydro-Electric Plant. Engr., vol 130, no. 3379, Oct. 1, 1920, pp. 324–326, 3 figs Plant, when completed, will develop 200,000 hp on head of from 80 ft. to 85 ft.

I

IGNITION

Alsop Device. Test of the Alsop All-Spark Ignition Device. Air Service Information Circular, vol. 1, no. 18, Sept. 15, 1920, 4 pp., 1 fig. Device is subsidiary spark gap which is inserted in high-tension circuit of ignition system.

Sparking Performance of System. The Effect of Shunted Resistance, or Plug Leakage, on the Sparking Performance of an Electrical Ignition System, G. E. Bairsto. Jl. Instn. Elec. Engrs., vol. 58, no. 292, June 1920, pp. 507–522, 22 figs. Tests made at Royal Aircraft Establishment, Farnborough, England, during 1917 to 1918, to determine effect of shunted resistance on spark voltage of most of leading types of electrical ignition systems in use. It was found that the quicker the rate of rise of secondary potential the less is fall of voltage with leakage. Following order of merit of various types was established: (1) rotating armature types with movable pole-shoes, (2) ordinary rotating-armature types, (3) sleeve inductor types, (4) polar inductor types; and (5) battery and coil systems.

Tests. Ignition from the Engineman's Viewpoint, George E. A. Hallett. Jl. Soc. Automotive Engrs., vol. 7, no. 5, Nov. 1920, pp. 475–479, 7 figs. Test results of single and double ignition systems on Liberty engine.

INDUSTRIAL MANAGEMENT

Inspection. Inspection: The Control of Quality—III George S. Radford. Indus. Management, vol 60, no. 5, Nov. 1920, pp. 331–335. Comparative study of various methods of inspection, such as centralized inspection, floor inspection, inspection of work in process, sampling, double inspection, pilot part tests, etc.

Opinions of Workers. What the Workers Think About Management—I, Albert Fry. Indus. Management, vol. 60, no. 5, Nov. 1920, pp. 322–327. Views of labor turnover, rate setting and managing men by ironworkers, carpenters, inspectors, blacksmiths, machinists, patternmakers and others.

Payroll Graph. Graphic Planning of Payroll Procedure, W. C. Bober. Indus. Management, vol. 60, no. 5, Nov. 1920, pp. 336–337, 1 fig. Chart based on labor routine of Mechanical Rubber Co., Cleveland.

Planning Department. New Department in Detroit Plant, Don F. Kennedy. Iron Age, vol. 106, no. 19, Nov. 4, 1920, pp. 1177–1179. Duties of factory planning engineer at Timken-Detroit Axle Co.'s Detroit plant.

Planning Department Systems, John H. Van Deventer. Indus. Management, vol. 60, no. 5, Nov. 1920, pp. 373–376, 4 figs. How to visualize methods by mapping routine.

Production Systems. How a Factory Diplomat Aids Production. Factory, vol. 25, no. 9, Nov.

ENGINEERING INDEX (Continued)

1, 1920, pp. 1398–1400, 1 fig. Production methods of foundry in Illinois.

Modern Production Methods, W. R. Basset. Am. Mach., vol. 53, nos. 18 and 20, Oct. 28 and Nov. 11, 1920, pp. 798–802, 3 figs., and 889–891, 2 figs. Fundamental definitions and explanations of cost subdivision. Nov. 11: Method of allotting fixed charges to every department.

Routing Materials. Routing Considered as a Function of Up-to-Date Management—II, H. K. Hathaway. Indus. Management, vol. 60, no. 5, Nov. 1920, pp. 353–361, 10 figs. How to proceed when product consists of several parts.

Shipyards. Scientific Management in a Large French Shipyard—I, M. Lavallee. Eng. & Industrial Management, vol. 4, nos. 17 and 18, Oct. 21 and 28, 1920, pp. 515–519, 1 fig., and 547–553, 7 figs. Results obtained in 1914 at Penhoet Shipyard at St. Nazaire, France. From Bulletin de la Société d'Encouragement pour l'Industrie Nationale.

INDUSTRIAL RELATIONS

Employees' Magazines. Making the Plant Paper Pay, Edwin A. Hunger. Indus. Management, vol. 60, no. 5, Nov. 1920, pp. 341–344. Suggestions to editors of employees' magazines.

Employers' Control. Italy's Soviet Shows Weakness, Francis Miltoun. Iron Trade Rev., vol. 67, no. 19, Nov. 4, 1920, pp. 1271–1272. Collapse of short-lived uprising of workers in steel plants and factories is pointed out as illustrating interdependence of capital and labor.

Open-Shop Movement in U. S. Cleveland in Open-Shop Ranks. Iron Trade Rev., vol. 67, no. 19, Nov. 4, 1920, pp. 1264–1265. It is reported American Plan Association has been organized, with fully 70 per cent of employers coöperating.

Employes Uphold the Open Shop, A. J. Hain. Iron Trade Rev., vol. 67, no. 16, Oct. 14, 1920, pp. 1071–1076, 7 figs. How International Association of Machinists failed to obtain general advance of 25 per cent in wages for which it fought for a year at Cincinnati machine tool plants.

New Open-Shop Movement in Cleveland. Iron Age, vol. 106, no. 19, Nov. 4, 1920, pp. 1201–1202. American Plan Association was recently organized. Purpose of organization is to establish open shop principle in industrial relations.

Public Sponsors Open-Shop Associations. Iron Trade Rev., vol. 67, no. 20, Nov. 11, 1920, pp. 1339–1345 and pp. 1348–1350, 5 figs. It is reported that American Federation is to be established soon. Purpose of federation will be to secure and establish open-shop principle in industrial relations.

Open Shops, Arguments in Favor of. The Human Factor in Industry, Alexander Ramsay. Jl. Inst. Mech. Engrs., no. 6, Oct. 1920, pp. 709–715 and (discussion) pp. 716–729. Urges employers to cultivate more open shop policy.

Settlement of Disputes. The Settlement of Labor Disputes, Henry J. Allen. Elec. Ry., Jl., vol. 56, no. 16, Oct. 16, 1920, pp. 751–753. Experience in Kansas cited to illustrate fundamental relations of workers and public welfare.

Unionized Shops. An Example of Putting Friendliness into a Unionized Shop, Harry Tipper. Automotive Industries, vol. 43, no. 18, Oct. 28, 1920, pp. 882–883. Writer quotes from English employer to show that open shop is not necessary to arrive at complete accord between workers and management.

Whitley Shop Councils. See EMPLOYEES' REPRESENTATION, Shop Committees.

INDUSTRIAL RAILWAYS

Factory Railway System. Conveying in Factories with Special Regard to Works Railway Operation (Das Transportwesen in Fabriken mit besonderer Berucksichtigung des Werkbahnbetriebes), R. Kampe. Betrieb, vol. 2, no. 15, Aug. 1920, pp. 405–407, 2 figs. Gives general fundamental principles and requirements, which should be considered in the organization of a transportation system, especially of a factory railway system.

INDUSTRIAL TRUCKS

Steel Industry. Trucks Win Place in Steel Traffic as Railroads Fail, Myers L. Feiser. Iron Trade Rev., vol. 67, no. 17, Oct. 21, 1920, pp. 1127–1129, 5 figs. Steel carried in motor trucks from mill to consumer or to car for shipment to consumer is estimated at more than 100,000 tons monthly.

INDUSTRY

Australia. The Industrial Development of Australia, Ernest L. Little. Am. Mach., vol. 53, no. 19, Nov. 4, 1920, pp. 842–843. Statistics showing progress within last ten years.

Mexico. Mexico's Industrial Progress Since Diaz, John E. Kelly. Eng. & Min. Jl., vol. 110, no. 20, Nov. 13, 1920, pp. 941–943. Nearly all railroad construction now under way planned under Carranza. Oil exports tripled in seven years. Metal output during revolutionary period indicative of mining activities.

INSULATORS

European Practice. Features of European Insulator Testing Practice, B. Schapira. Elec. Rev., (Chicago), vol. 77, no. 19, Nov. 6, 1920, pp. 721–724, 8 figs. Two-part insulators of pin type are used for service below 70,000 volts. Tests are made of electrical and mechanical properties of individual parts and complete assembled units. Testing practice as carried on in Schomburg Works at Margarethenhutte, Germany.

High-Voltage. Surface Creepage and High-Voltage Insulation, T. Nishi. Jl. Am. Inst. Elec. Engrs., vol. 39, no. 11, Nov. 1920, pp. 949–959, 32 figs. Experiments made in Electrical Engineering Laboratory in Tokyo Imperial University and in High-Voltage Laboratory of Leland Stanford Junior University. It is concluded that main cause of erratic surface creepage is accumulation of free charge on surface of dielectric of which bushings insulators, etc., are made.

Testing. Testing Insulators in Factory and Field, Leslie N. Crichton. Elec. Jl., vol. 17, no. 11, Nov. 1920, pp. 506–509, 10 figs. Methods of Westinghouse Elec. & Mfg. Co.

INTERCHANGEABLE MANUFACTURE

Selective Assembly vs. Manufacturing for Selective Assembly, Earle Buckingham. Machy. (Lond.), vol. 17, no. 421, Oct. 21, 1920, pp. 82–83, 2 figs. Comparison of interchangeable and selective assembly manufacturing methods. Dimensions and tolerances on drawings for manufacturing on selective assembly basis.

Tolerances. Size Tolerances and Allowance Tolerance (Grössentoleranzen und Passungstoleranz), J. Kirner. Betrieb, vol. 2, no. 16, Sept. 1920, pp. 426–427, 4 figs. The preliminary conditions for unlimited interchangeability. Points out that so-called allowance tolerance or inaccuracy of an allowance is result of the algebraic difference between maximum and minimum excess measurement or play of allowance.

INTERNAL-COMBUSTION ENGINES

Compound Type. Pourcel Compound Explosion Motor (Moteur compound à explosion, système Pourcel), Génie Civil, vol. 77, no. 15, Oct. 9, 1920, p. 299, 1 fig. Patented engine with two explosion cylinders and an expansion cylinder where explosion gases expand before being exhausted in atmosphere.

Cooling Devices. New Devices for the Cooling of Internal-Combustion Engines (Neue Luftkühler für Verbrennungsmotoren,) H. Pradel. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 43, nos. 31 and 34, July 30 and Aug. 20, 1920, pp. 233–234 and 260–262, 17 figs. Details of various new patents.

The Cooling of Internal-Combustion Engine. (Die Kühlung der Verbrennungsmotoren), H. Praetorius. Motorwagen, vol. 23, no. 23, Aug. 20, 1920, pp. 425–429, 12 figs. Review of new patents and devices in the field of engine cooling introduced for the purpose of increasing economy of engines and in view of the frequent necessity of employing heavier fuel.

Valves, Steel for. Steel for Valves of Combustion Motors, G. Gabriel. Iron Age, vol. 106, no. 20, Nov. 11, 1920, pp. 1249–1251. Requirements enumerated in light of troubles which experience has discovered in low weight engine. (To be continued.) Translated from La Technique Automobile et Aerienne.

[See also AEROPLANE ENGINES; AUTOMOBILE ENGINES; DIESEL ENGINES; GASOLINE ENGINES; HEAVY-OIL ENGINES; OIL ENGINES; SEMI-DIESEL ENGINES.]

IRON

Electrolytic. Reheating of Electrolytic Iron (Le recuit du fer électrolytique), Jeane Cournot. Revue de Métallurgie, vol. 17, no. 8, Aug. 1920, pp. 568–570, 6 figs. Experimental study of best procedure to remove hydrogen remaining in iron when issuing from electrolytic bath.

Soft. Soft Iron (Ueber Weicheisen), P. Goerens and P. Fischer. Betrieb, vol. 2, no. 16, Sept. 1920, pp. 432–436, 20 figs. Account of mechanical and physical investigations of the nearly chemically pure WW soft iron produced in the open-hearth furnaces of the Fried. Krupp Works in Essen-Ruhr, the elasticity and shock resistance of which in cold state is said to exceed that of all kinds of mild steel produced in large quantities, and in many cases is a perfect substitute for copper. Abstracted from the Krupp Monthly Jl. (Jan. 1920).

IRON CASTINGS

Cleaning with Sand Blast. The Sand Blast in the Foundry, O. Bertoya. Metal Industry (Lond.), vol. 17, no. 17, Oct. 22, 1920, pp. 321–323, 9 figs. Comparative tests of time required to clean castings by hand and by sand blasting.

Standardization of. Standardizing of Gray Iron Samples, Edward J. Fowler. Foundry, vol. 48, no. 21, Nov. 1, 1920, pp. 876–877. It is said that lack of recognized standards which specify method of taking samples of gray iron castings for test purposes greatly impairs work of laboratory.

IRON METALLURGY

Direct Process. A Direct Process for Making Iron and Steel from Ore, James W. Moffat. Iron and Steel of Can., vol. 3, no. 9, Oct. 1920, pp. 271–274, 3 figs. Process patented by writer, in which reduction is accomplished in separate mechanism and melting down of metal and its subsequent refining take place in electric furnace. Blast furnace is eliminated and metal reduced from ores of all types. Process is said to be applicable to certain non-ferrous metals.

IRON ORE

Australian. The Iron Ore Deposits at Yampi Sound, West Australia, A. Montgomery. Min. Mag., vol. 23, no. 4, Oct. 1920, pp. 203–122, 12 figs. Description of iron ore deposits on Koolan and Cockatoo Islands situated in Yampi Sound off northern coast of West Australia.

Canadian. Iron Ores of Commerce with Special Reference to Canadian Deposits, Samuel Groves. Iron and Steel of Can., vol. 3, no. 9, Oct. 1920, pp. 267–270, 1 fig. Classification of commercial iron ores. (To be continued.) Report of Ontario Bureau of Mines.

IRRIGATION

Canada. The Legal Phases of Irrigation Development in Alberta, H. B. Muckleston. Jl. Eng. Inst. Canada, vol. 3, no. 11, Nov. 1920, pp. 510–514. History of irrigation law in general, developments in Alberta, and procedure under present laws.

Washington State. Unprecedented Design Involved in Irrigation Project. Eng. News-Rec., vol. 85, no. 20, Nov. 11, 1920, pp. 944–946, 2 figs. To bring water 130 miles to 1,753,000-acre Columbia basin in Washington. Viaduct, siphons and tunnels of unusual size.

L

LABOR

International Action Affecting. Historical Survey of International Action Affecting Labor, U. S. Dept. of Labor, Bur. of Labor Statistics, no. 268, Aug. 1920, 294 pp. Includes brief account of international political labor movement as seen in early International and its later organization as International Socialist Bureau. Describes briefly international trade-union movement, international organizations of "social reformers" interested in labor problems, considering particularly International Association for Labor Legislation, and recounts efforts of Governmental conferences to arrive at agreements as respects control of labor conditions within their respective jurisdictions. Analysis is made of treaties and conventions entered into by various Governments. Survey covers international work up to 1914.

LAPPING

Modern Practice. Modern Lapping Practice, Edward K. Hammond. Machy. (N.Y.), vol. 27, no. 3, Nov. 1920, pp. 209–217, 19 figs. Review of developments in lapping practice including abrasives used and lap-charging methods, lapping thread gages, snap gages, measuring wires, flat surfaces, ring gages, die-casting dies, T-slots, etc.

LATHES

Turret. Tooling Acme Turret Lathes. Machy. (Lond.), vol. 17, no. 419, Oct. 7, 1920, pp. 1–5, 12 figs. Tooling equipment for performing turret-lathe operations on friction pulleys, aluminum pistons, gear blanks and other machine parts.

Turret Lathe Design and Construction. Mach. (Lond.), vol. 17, no. 420, Oct. 14, 1920, pp. 41–44, 5 figs. Based on examination of four American and one English machines.

LIGNITE

Briquetting. The Briquetting of Lignites, R. A. Ross. Dominion of Canada, report no. 1, 1918, 29 pp. Procedure and equipment are recommended.

Carbozite. The Low-Temperature Carbonization of Low-Grade Fuels, Especially of Lignites (Nochmals: Die Tieftemperaturverkohlung geringwertiger Brennstoff, insbesondere der Braunkohle), H. Bansen. Braunkohle, vol. 19, no. 17, Aug. 7, 1920, pp. 217–220. Refers to article by Theiler in same journal (vol. 18, no. 33, Nov. 15, 1919) on manufacture of carbozite, a lignite product whose heating value is said to be three times that of lignite. Critical discussion of its merits from technical and economical standpoint.

LIGHTING

Bibliography. Illumination Bibliography. Trans. Illuminating Eng. Soc., vol. 15, no. 7, Oct. 9, 1920, pp. 385–391. Prepared by Committee on education of Illuminating Eng. Soc. It covers books published in recent years up to June 1920.

Developments. Report of the Committee on Progress. Trans. Illuminating Eng. Soc., vol. 15, no. 7, Oct. 9, 1920, pp. 425–493. Extensive survey of recent developments in gas and electric light.

Electric Signs. Engineering Features of Electric Sign Lighting. Bul. Eng. Dept. Nat. Lamp Works, Gen. Elec. Co., bul. no. 15a, March 15, 1916, 35 pp., 20 figs. Engineering features involved in readability of electric signs, wiring of electric signs and cost of their operation.

Industrial. Industrial Lighting, Ward Harrison and H. H. Magdsick. Bul. Eng. Dept. Nat. Lamp Works, Gen. Elec. Co., bul. no. 20a, Sept. 10, 1919, 95 pp., 79 figs. Requirements which must be fulfilled in design of satisfactory installations. Data on Mazda lamps. Discussion of reflecting and diffusing equipment. Study of lighting of yards and foundries. Cost data of industrial lighting.

Modern Industrial Lighting for Oregon, F. H. Murphy. Elec. World, vol. 76, no. 17, Oct. 23, 1920, pp. 820–823, 5 figs. Features of industrial lighting code adopted by Oregon. Provision is made for raising standards as better lighting practice develops.

Proper Lighting Means Efficiency, James Brakes, Jr. Iron Trade Rev., vol. 67, no. 16, Oct. 14, 1920, pp. 1061–1062 and 1067, 2 figs. Self-cleaning lamp fixtures. (Abstract.) Paper read before Am. Foundrymen's Assn.

Machine Shops. Illumination of Machine Tools, G. Wagschal. Elec. World, vol. 76, no. 19, Nov., 6, 1920, pp. 925–926, 4 figs. Sufficient illumination is said to be obtained over machines with intensity of 15.35 ft. candles in plant of Central Gear Co.

Stores. Store Lighting. Bul. Eng. Dept. Nat. Lamp Works, Gen. Elec. Co., bul. no. 29, June 5, 1917, 40 pp., 14 figs. Discussion of various types

descent Lamp Circuits. Bul. Eng. Dept. Nat. Lamp Works, Gen. Elec. Co., bul. no. 25, Sept. 20, 1915, 23 pp. 11 figs. Factors in design and operation of streets series incandescent systems.

Street Series Mazda Lamps. Bul. Eng. Dept. Nat. Lamp Works, Gen. Elec. Co., bul. no. 11C, Oct. 15, 1915, 10 pp., 6 figs. Characteristic curves of Mazda street series lamp.

LIGHTNING PROTECTION

4000-Volt Circuits. Lightning Protection of 4000-volt lines, Thomas Commerford Martin. Elec. World, vol. 76, no. 20, Nov. 13, 1920, pp. 973–977 5 figs. Experimental investigation showed that density of lightning arresters on an electrical distribution system is far more important than type of arrester.

Studies in Lightning Protection on 4000-Volt Circuits—II, D.W. Roper. Jl. Am. Inst. Elec. Engrs., vol. 39, no. 11, Nov. 1920, pp. 960–975, 20 figs. Factors which affect lightning-arrester performance. Curves showing relative merits of various types of lightning arresters.

Spark Gaps. Lightning Arrester Spark Gaps—II, Chester T. Allcutt. Jl. Am. Inst. Elec. Engrs., vol. 39, no. 11, Nov. 1920, pp. 939–943, 12 figs. Data giving discharge characteristics of commercial type of impulse gap under different conditions. Factors that determine degree of protection afforded by lightning-arrester spark gap. Definition of "protection factor" and curves giving protection factor of certain types of gap.

Tests. Life and Performance Tests of O F Lightning Arresters, N. A. Lougee. Jl. Am. Inst. Elec. Engrs., vol. 39, no. 11, Nov. 1920, pp. 944–948, 5 figs. Performed at laboratories of General Electric Co.

LIME

Manufacture. The Manufacture of Lime for Chemical and Metallurgical Purposes—III, Richard K. Meade. Chem. & Metallurgical Eng., vol. 23, no. 19, Nov. 10, 1920, pp. 929–933, 3 figs. Methods of heating rotary kilns. Description and comparison of pulverized coal and producer gas installations. Boilers in series with kiln. Power consumption. Cost data.

LOCOMOTIVE BOILERS

Welding Flue Points to Boiler Tubes. Welding Flue Points to Boiler Tubes, Charles W. Geiger. Welding Engr., vol. 5, no. 10, Oct. 1920, pp. 44–46, 5 figs. Method developed by Charles S. Coleman of Santa Fe Railroad Co.

LOCOMOTIVES

Boosters. Operating Tests of a Pacific Type Booster Locomotive. Ry. Age, vol. 69, no. 17, Oct. 22, 1920, pp. 699–702, 6 figs. Additional tractive effort of booster has increased tonnage rating for division on New York Central.

Cylinder Parts. Cast Iron for Locomotive-Cylinder Parts, C. H. Strand. Technologic Papers, Bur. of Standards, no. 172, Sept. 11, 1920, 25 pp., 10 figs. Records of investigation of mechanical, chemical and metallographic properties of packing rings of various service mileages, and also of arbitration test bars, chill test blocks, and miscellaneous samples from various makers. It is concluded that existing specifications are insufficiently rigid as to requirements for mechanical tests and specification is proposed with revisions in accordance with results of these tests.

Electric. See ELECTRIC LOCOMOTIVES.

Lubrication of. Lubricator Locomotive Gears (Schmiergefässe am Lokomotiv-Triebwerk), H. Bauer. Verkehrstechnik, vol. 37, no. 21, July 25, 1920, pp. 298–299, 1 fig. Automatic lubricating device called Mobil, which has been used for a number of years for works railway locomotives and is now being used for trunk-line locomotives of German National Ry. Administration.

Mountain Type. Mountain Type Locomotives for the New Haven. Ry. Mech. Engr., vol. 94, no. 11, Nov. 1920, pp. 685–688, 8 figs. Equipment includes feedwater heaters and provision for future application of booster.

No-Load Arrangements. No-Load Arrangements on Locomotives (Leerlaufeinrichtungen an Lokomotiven), F. Meineke. Zeit. des Vereines deutscher Ingenieure, vol. 64, no. 39, Sept. 25, 1920, pp. 784–788, 25 figs. Describes typical constructions of air inlet valves, by-pass valves, etc., but states that there is no construction type adaptable to all cases. Aspects governing selection of suitable devices.

Oil-Burning. English Railways Experiment with Fuel Oil. Ry. Mech. Engr., vol. 94, no. 11, Nov. 1920, pp. 692–696. Description of Scarab fuel oil burning apparatus tested on London and Northwestern Ry.

Oil Burning on Locomotives. Ry. Engr., vol. 41, no. 489, Oct. 1920, pp. 414–418, 7 figs. Tests on London & Northwestern Railway with locomotive of "Precursor" class, equipped with Scarab oil burning apparatus.

Pennsylvania R. R. 2-10-0-Type Locomotive; Pennsylvania Railroad. Eng., vol. 110, nos. 2860 and 2861, Oct. 22 and 29, 1920, pp. 538–539, 23 figs., partly on supp. plates, and 586–587, 28 figs. Characteristics: Total weight in working order, 371,800 lbs.; driving wheels, diameter, 62 in.; cylinders, $30^1/_2$ in x 32 in.; boiler pressure, 250 lb. per sq. in.; total heating surface, 4334 sq. ft.; 22, 1920, pp. 687–696, 8 figs. Locomotive repair shops of Union Pacific Railroad at Cheyenne, Wyo.

Locomotive Repair Shop Organization and Methods. Ry. Engr., vol. 41, no. 489, Oct. 1920, pp. 410–412. Best method of obtaining maximum output, consistent with good work, from locomotive repair shops.

Wheel Balancing. Calculation of the Counterbalances in Locomotive Driving Wheels (Berechnung der Gegengewichte in Lokomotiv-Triebrädern), H. Igel. Organ für die Fortschritte des Eisenbahnwesens, vol. 57, no. 15, Aug. 1, 1920, pp. 153–156, 15 figs. Gives calculations for different types of locomotives.

Locomotive Wheel Balancing Machine. Ry. Mech. Engr., vol. 94, no. 11, Nov. 1920, pp. 719–720, 5 figs. Device used in British railroad shops tests wheels by rotating them in spring supported bearings.

M

MACHINE GUNS

Pocket Types. A Pocket Machine Gun, E. C. Crossman. Sci. Am., vol. 123, no. 16, Oct. 16, 1920, pp. 405–413–414, 4 figs. Types of pocket machine gun magazines and how gun is used by New York Police Department.

MACHINE-TOOL INDUSTRY

Germany. The German Machine Tool Industry. Machy. (N.Y.), vol. 27, no. 3, Nov. 1920, p. 232. It is reported that German manufacturers are no longer able to compute with prices on world's market.

The German Machine-Tool Industry Today. Am. Mach., vol. 53, no. 20, Nov. 11, 1920, pp. 923–924. Depression ascribed to overstretching prices.

Sweden. The Swedish Machine Tool Industry, S. E. Osmar. Mach. (N.Y.), vol. 27, no. 3, Nov. 1920, p. 227. Industry is described as very dull at present,a nd it is said that there is not immediate prospect for improvement.

MACHINE TOOLS

Developments. Recent Machine Tool Developments—XVI, Joseph Horner. Eng., vol. 110, no. 2859, Oct. 15, 1920, pp. 494–498, 16 figs. Milling machines.

Frames. A New Stiffening Construction for Machine Tool Frames (Neue Versteifungsbauart für Werkzeugmaschinenbetten), Ernst Peters. Werkstattstechnik, vol. 14, no. 16, Aug. 15, 1920, pp. 441–442, 5 figs. According to new method, frame of machine tool is provided with diagonal stiffening ribs in place of the rectangular ribs heretofore in use, in order to increase the accuracy of work and resistance against high stresses.

Plants. Service Department in a Machine Tool Plant. Machy. (N.Y.), vol. 27, no. 3, Nov. 1920, pp. 261–263, 3 figs. Outline of purpose, organization, equipment and methods of service department of Heald Machine Co., Worcester, Mass.

Regulating Motors. Shortening of Working Period and Reduction of Power Consumption through Regulating Motors (Abkürzung der Arbeitzeit und Verminderung des Kraftbedarfs durch Reguliermotoren), O. Pollok. Betrieb, vol. 2, no. 14, Aug. 1920, pp. 341–347, 1 fig. It is shown that machine tools with regulating motors prevent the lower outputs of all mechanically graded machines and, by control of the speeds, effect considerably higher outputs; a very great saving in power is effected by simplification of drive through the regulating motor. Recommendations for standards.

Safety Standards. Safety Standards of the Industrial Board. Commonwealth of Pennsylvania, Dept. of Labor & Industry, vol. 1, no. 5, 7 pp. Rules to safeguard workers in industries in which machine tools are used.

Speed Steps, Standardization of. Standardization of Speed Steps in Machine Tool Construction (Vereinheitlichung der Grösse des Stufensprunges im Werkzeugmaschinenbau), Ernest J. Wild. Der praktische Maschinen-Konstrukteur, vol. 53, no. 36, Sept. 9, 1920, pp. 155–157. Values are developed based on assumption that maximum cutting speed in practically all theoretical working diameters is the same.

MAGNETIC TESTING

Defectoscope. New Magnetic Testing Apparatus. Iron Age, vol. 106, no. 18, Oct. 28, 1920, pp. 1125–1128, 7 figs. Defectoscope, a device for magnetic testing of steel.

MALLEABLE CASTINGS

Manufacture in Electric Furnace. Malleable Made by Triplex Process, H. A. Schwartz. Foundry, vol. 48, no. 357, Oct. 15, 1920, pp. 815–817 and 825, 4 figs. Patented process involving use of cupola, side-blow converter and electric furnace. Details of operation and metallurgical reactions are explained. Paper read before Am. Foundrymen's Assn.

MARINE ENGINES

See DIESEL ENGINES, Marine.

MARKETS

Terminal, New York City. $75,000,000 Terminal Market Planned for New York. Manufacturers Rec., vol. 78, no. 19, Nov. 4, 1920, pp. 151–152,

Developments. Precision Instruments in Engineering Works (Le misure di precisione nelle officiene meccaniche), Vernon I. N. Williams. Revista d'Ottica e Meccanica di Precisione, vol. 1, nos. 7–8, Mar.–Apr. 1920, pp. 129–145, 34 figs. Survey of developments throughout the world.

Phosphoroscope. A Special Form of Phosphoroscope, W. S. Andrews. Gen. Elec. Rev., vol. 23, no. 10, Oct. 1920, pp. 856–857, 6 figs. Type developed by writer for visual observation of phosphorescent and fluorescent light emitted by various compounds when excited by ultra-violet light.

METAL INDUSTRY

German. The Metal Supply Problem in German—I, C. A. Heise. Iron Age, vol. 106, no. 20, Nov. 11, 1920, pp. 1295–1297. How war shortages were met by substitutions. Effect of latter on present and future consumption of copper and tin.

METALLURGY

Developments in. Recent Progress in the Control of Metallurgical Products (Les progrès récents des méthodes de controle des produits métallurgiques), Leon Guillet. Génie Civil, vol. 77, no. 16, Oct. 16, 1920, pp. 313–316, 7 figs. Industrial uses of equilibrium diagrams of alloys (Concluded).

METALS

Crystal Growth. Crystal Growth and Recrystallisation in Metals, H. C. H. Carpenter and Miss C. F. Elam. Eng., vol. 110, no. 2858, Oct. 8, 1920, pp. 486–490, 16 figs. Review of theories of crystal growth in light of evidence obtained in experimental research. (Concluded.) (Abstract.) Paper read before Inst. of Metal.

Rust Prevention. Preventing Rust at High Temperatures, Robert June. Sci. Am., vol. 123, no. 16, Oct. 16, 1920, pp. 404 and 412–413, 4 figs. Aluminum-coated metals that will go to melting point without formation of scale.

Supra-Conduction of. The "Supra-Conducting Condition" of Metals (Der "supraleitende Zustand" von Metallen), C. A. Crommelin. Physikalische Zeitschrift, vol. 21, nos. 10, 11 and 12, May 15, June 1 and 15, 1920, pp. 274–280, 300–304 and 331–336, 11 figs. Discussion of a series of investigations on the resistance of metals carried out in Prof. Kamerlingh Onnes' cryogenic laboratory of Leiden at temperatures which can be reached solely with liquid helium, and which led to the discovery of the so-called supra-conducting condition of different metals. Address delivered before Physical Soc. at Leiden in Feb. 1919.

Thermostatic. Thermostatic Metal. Automotive Industries, vol. 43, no. 17, Oct. 21, 1920, p. 819. New thermostatic metal developed by H. A. Wilson Co., and being placed on market under trade name "Wilco."

METRIC SYSTEM

Arguments Against Adoption in U. S. Anti-Metric Resolutions. Am. Mach., vol. 53, no. 20, Nov. 11, 1920, pp. 916–917. Resolutions against compulsory adoption of metric system in U. S., passed by Automotive Wood Wheel Manufacturers' Assn., Hickory Products Assn., New Jersey Lumbermen's Assn., Kentucky Manufacturers' Assn., Am. Assn. of Engrs., Hydraulic Soc., Compressed Air Soc. and many other associations and Chambers of Commerce.

The Metric System and International Trade, Harry Alcock. Nature (Lond.), vol. 106, no. 2658, Oct. 7, 1920, pp. 169–170. Comment on Report on Compulsory Adoption of the Metric System in the United Kingdom, submitted by metric committee appointed by Conjoint Board of British Scientific Societies. Recommendations include plea for continued use of British units by Department of State.

The English and the Metric Measuring System A Comparison, C. C. Stutz. Am. Mach., vol. 53, no. 20, Nov. 11, 1920, pp. 911–913. It is held that metric units are either too large or too small for every day requirements in industry.

MILLING

Circular Segments. Milling Fixture for Circular Segments. Machy. (N.Y.), vol. 27, no. 3, Nov. 1920, pp. 229–230, 3 figs. Features of construction of hinged milling fixtures designed for use in performing gang milling operations in circular segments.

Continuous vs. Station. Continuous versus Station Milling. Machy. (Lond.), vol 17, no. 422, Oct. 28, 1920, pp. 106–108, 4 figs. Comparison of results that are obtained by both methods of milling on identical work when using similar machines in interchangeable manufacture.

MILLING CUTTERS

Manufacture. Making "Curvex" Milling Cutters. Machy. (N.Y.), vol. 27, no. 3, Nov. 1920, pp. 250–258, 17 figs. Methods and equipment employed by Pratt & Whitney Co., Hartford, Conn., in manufacture of formed milling cutters with helical flutes.

MILLING MACHINES

Locomotive Parts. Milling Machines for Crown-Bar Frames of the A. Borsig Locomotive Factory (Barrenrahmenfräsmaschinen der Lokomotivfabrik A. Borsig.) Werkstattstechnik, vol. 14, no. 14, July 15, 1920, pp. 390–395, 16 figs. Details of special machine designed by engineer of Schiess

ENGINEERING INDEX (Continued)

Machine Factory, Ltd., Düsseldorf, in the Borsig works, Specifications: max. length of frames to be cut, 11,000 mm.; max. height, 900 mm.; diam. of cutter spindle, 90 mm.; speed of cutter spindle, 320 r.p.m.; speed of motor, 1250 r.p.m.; etc. Machines are constructed in two types, with two and with three uprights, the latter serving for the simultaneous machining of two locomotive crown-bar frames.

MINE TIMBERING

Preservative Treatment. Saving Mine Timbers from Decay. Forest Products Laboratory, Technical Notes, Oct. 15, 1920, no. 110, 1 p. Three preservatives have been found suitable for mine work: coal-tar creosote, zinc chloride and sodium fluoride.

MINING INDUSTRY

Norway. The Mining and Metallurgical Industry of Norway, Matthew R. Blish. Eng. and Min. Jl., vol. 110, no. 18, Oct. 30, 1920, pp. 856–858. Brief review of resources and past and present production. Iron still most important metal, with copper and molybdenum of secondary interest. Development dependent upon increased application of electric power.

MOLDING MACHINES

European Types. European Equipment Progressive, H. Cole Estep. Foundry, vol. 48, no. 357, Oct. 15, 1920, pp. 818–825, 21 figs. Most of molding-machine manufacturers of Europe are found in Great Britain, France, and Germany. Although war exerted depressing effect upon new molding machines, it served to develop to high efficiency those already in service. Excellence is shown in smaller types. Paper read before Am. Foundrymen's Assn.

MOTOR BUSES

Street Cars vs. Bridgeport Tries the Jitney. Aera, vol. 9, no. 3, Oct. 1920, pp. 239–253, 6 figs. Experiment of eight weeks without trolleys is said to have shown motor bus incapable of furnishing satisfactory transportation.

MOTOR PLOWS

British. Fowler Ploughing Machinery. Eng., vol. 110, no. 2859, Oct. 15, 1920, pp. 507–508 and 510, 3 figs. Machines built by John Fowler & Co., Ltd. Double steam engine set rated at 8 hp. nominal is used.

Internal Combustion Cable Ploughing Engine. Eng., vol. 100, no. 2859, Oct. 15, 1920, pp. 506–507, 9 figs. Weight is $3^1/_4$ tons for each engine with fuel and spuds, and power developed is 32 b.hp. Four-cylinder Dorman engine arranged to burn paraffin is used.

MOTOR TRUCKS

British. $7^1/_2$-Ton Six-Wheel Commerical Vehicles. Eng., vol. 110, no. 2859, Oct. 15, 1920, pp. 518–520, 5 figs. Engine is of four-cylinder type and develops 47 b.hp. at 1000 r.p.m. It drives through Ferodo-lined cone clutch with aluminium male member.

Olympia Show. Exhibits at the Commercial Motor Exhibition. Eng., vol. 110, no. 2860, Oct. 22, 1920, pp. 535–536 and 542, 6 figs. Leading features of exhibit at Olympia.

The Commercial Motor Exhibition—I. Engr., vol. 130, no. 3382, Oct. 22, 1920, pp. 400–402 and 404, 13 figs. Details of principal exhibits.

The Commercial Motor Exhibition. Eng., vol. 110, no. 2860, Oct. 22, 1920, pp. 546–549. Editorial comments on progress as shown by exhibits at Olympia show.

Worm Drives. Tests on Rear-Axle Worm Drives for Trucks, Kalman Heindlhofer. Mech. Eng., vol. 42, no. 11, Nov. 1920, pp. 613–615, 10 figs. Determination of efficiencies under load variations. Efficiency curves showing results with four sets of gears in mesh are included. Effect of oil temperature in worm thrust bearing, on efficiency of drive is given, high efficiencies being derived at higher oil temperatures.

MOTORSHIPS

European Built. Motorship Building in Europe. Marine Eng., vol. 25, no. 11, Nov. 1920, pp. 921–923, 3 figs. Particulars of six new 14,000-ton motor vessels.

Standardization. Standardization of Motor Ships. Times Eng. Supp., vol. 16, no. 552, Oct. 1920, p. 304. Growth of policy.

N

NICKEL STEEL

Classification. The Anomaly of the Nickel-Steels, Charles Edouard Guillaume. Physical Soc. of London, Proc., vol. 32, part 5, Aug. 15, 1920, pp. 374–404, 15 figs. Classification by means of magnetic properties, changes of volume, progressive and transitory variations. Fifth Guthrie lecture.

NOZZLES

Calibration. Calibration of Nozzles for Measurement of Air Flowing into a Vacuum, Wm. L. De Baufre. Mech. Eng., vol. 42, no. 11, Nov. 1920, pp. 607–609 and p. 650, 6 figs. Investigation of flow of elastic fluid through nozzles having well-rounded entrances, effects of frictional resistance and of moisture in atmosphere when fluid is atmospheric air being taken into account. It is shown that rate of flow of dry air decreased with increases of moisture. Investigation was conducted at U. S. Naval Engineering Experiment Station, Annapolis, Md.

Tests. Investigations of Diffusers (Ueber Diffusoruntersuchungen). Der praktische Maschinen-Konstruckteur, vol. 53, no. 31, Aug. 5, 1920, pp. 280–282, 1 fig. Abstract of report on results of measurements on a steam diffuser carried out in the machine-construction laboratory of the Charlottenburg Technical Academy, tests being carried out according to two aspects, namely, variable condition of steam with a given nozzle, and different nozzles with corresponding initial condition.

O

OIL

Crude. Experimental Determination of Evaporation Losses from Crude Oil during Piping and Storage on Oil Leases, A. R. Elliott. Reports of Investigations, Bur. of Mines, Dept. of Interior, serial no. 2169, Oct. 1920, 3 pp. Tests made to determine quantities and values lost.

OIL ENGINES

British. Some Lincolnshire Oil-Engines, F. H. Livens. Jl. Instn. Mech. Engrs., no. 6, Oct. 1920, pp. 673–697 and (discussion) pp. 697–707, 18 figs. Survey of most important methods of vaporization and ignition adopted and of increasing economy effected from time to time.

Hot-Bulb. 40-B.HP. Marine Two-Cycle Hot-Bulb Oil Engine. Eng., vol. 110, no. 2861, Oct. 29, 1920, pp. 568–569, 26 figs. partly on supp. plate. Engine is fitted with reversing gear and with bilge circulating air and lubricating pumps. It has 7 in. cylinders by 8 in. stroke and runs at 400 r.p.m. developing 40 b.hp. at that speed. Engine is manufactured by Norris, Henty & Gardners, Ltd., London.

Velocity of Fuel Injection. Determination of the Velocity of Solid Fuel Injection, David Turcott Gas Engine, vol. 22, no. 11, Nov. 1920, pp. 318–319. Experimental study. Velocity of injection in two-stroke cycle 30 hp. oil engines varied from 103 to 109 ft. per sec. with load from 0 to 100 per cent.

[See also HEAVY-OIL ENGINES.]

OIL FUEL

Economics. Fuel Oil as a Means to Increased Capacity, C. C. Lance. Ry. Mech, Engr., vol. 94, no. 11, Nov. 1920, pp. 723–724. Critical boiler plant condition relieved and efficiency improved by use of fuel oil in place of coal.

Measurement Policy. A National Liquid Fuel Policy, R. S. McBride. Power, vol. 52, no. 17, Oct. 26, 1920, pp. 665–669, 2 figs. Possibilities of producing substitutes in liquid fuel supply. Best method for distributing available supplies among various classes of users when total demand exceeds available supplies.

OIL SHALES

Commercial Retorting. Commercial Retorting of Oil Shales, Louis Simpson. Chem. & Metallurgical Eng., vol. 23, no. 16, Oct. 20, 1920, pp. 789–791. Applicability of methods used in Scotland to American oil shales.

Indiana. Oil Shales of Indiana, John R. Reeves. Eng. & Min. Jl., vol. 110, no. 20, Nov. 13, 1920, pp. 954–955. Advantages of location and homogeneous character of raw material warrant expectation of commercial possibilities when experimental data determine satisfactory method of recovery. Results of dry and steam distillation tests.

OIL WELLS

Shutting Off Water. Shutting Off Water in Oil Wells. Petroleum World, vol. 17, no. 242, Nov. 1920, pp. 448–450, 2 figs. Patented process for shutting off water in oil wells by freezing limited area surrounding well casing.

ORES

Classifier. The Mitchell Electric Vibrating Screen, Chas. W. Stimpson. Monthly Jl. Utah Soc. Engrs., vol. 6, no. 4, Sept. 1920, pp. 51–54, 10 figs. partly on 2 supp. plates. Moving force is electric vibrator unit, applied from beneath screen cloth.

OVENS

Core Baking. Core Baking in Electrically Heated Ovens, Jesse L. Jones. Metal Industry (N. Y.), vol. 18, no. 10, Oct. 1920, pp. 450–451, 2 figs. New electric core oven developed by Westinghouse Electric & Mfg. Co. Records of its operation. Paper read before Am. Foundrymen's Assn.

OXY-ACETYLENE CUTTING

Cast Iron. Cutting Cast Iron with the Oxy-Acetylene Flame, Alfred S. Kinsey. Acetylene Jl., vol. 22, no. 5, Nov. 1920, pp. 264–269 and p. 272, 4 figs. Method of procedure. Paper read before Am. Foundryman's Assn.

OXY-ACETYLENE WELDING

Trade School for. An Acetylene Welding and Cutting Institute. Sheet Metal Worker, vol. 11, no. 11, Oct. 29, 1920, pp. 307–310, 4 figs. School established and conducted by equipment manufacturer where sheet metal mechanics and others are given instruction in these branches of industry.

[See also AUTOGENOUS WELDING.]

OXYGEN

Production in Germany. Oxygen and Nitrogen Production in Germany, R. Linde. Eng. Progress, vol. 1, no. 10, Oct. 1920, pp. 297–300, 5 figs. Low temperature processes. Modern installations for production of nitrogen and oxygen. Largest installations of world. Practical use of oxygen and nitrogen.

P

PAINTING

Spray. The Vortex Painter. Commercial America, vol. 17, no. 5, Nov. 1920, p. 51. Nozzle has two openings, a central opening for paint and an annular opening around center from which air is discharged as veritable blast under pressure approximating 60 lb. per sq. in.

PATTERNS

Wheels. Wheel Patterns. Machy. (Lond.), vol. 17, no. 421, Oct. 21, 1920, pp. 91–93, 7 figs. Making of patterns for webbed and flanged wheels as well as for wheels with arms. Methods used for molding wheels without complete patterns.

PETROLEUM

Production. Liquid Fuels—Wanted: A National Policy, R. S. McBride. Eng. and Min. Jl., vol. 110, no. 17, Oct. 23, 1920, pp. 823–825, 1 fig. It is urged that consideration be given to need for securing maximum oil production, reduction of consumption, or finding of new sources, to obtaining of substitutes and to adequate distribution of available supplies.

[See also OIL, Crude.]

PIPE, CONCRETE

Joint for. New Type of Concrete Pipe Joint. Eng. World, vol. 17, no. 5, Nov. 1920, pp. 360–361. Use of machined casting for bell and spigot rings.

PLATINUM

Colombia, S. A. Platinum in Colombia, J. Ovalle. Eng. & Min. Jl., vol. 110, no. 19, Nov. 6, 1920, pp. 907–908. Foreign capital to realize future possibilities of industry. Output of Choco region increasing. That of Urals passed its peak before war. Ordinary methods of production employed.

PNEUMATIC MAIL TUBES

See COMPRESSED AIR, Pneumatic Mail Despatch.

POLES

Preservative Treatment. Preservative Treatment of Wood Poles, R. V. Achatz. Purdue University, Publications Eng. Dept., vol. 4, no. 2, June 1920, 54 pp., 18 figs. Practices in Indiana. Specifications for preservatives adopted by Am. Ry. Eng. Assn., Nat. Elec. Light Assn. and U. S. Shipping Board Emergency Fleet Corporation.

The Kyanizing of Wooden Poles (Beitrag zur Kyanisierung von Holzmasten), Robert Nowotny. Elektrotechnik u. Maschinenbau, vol. 38, no. 22, May 30, 1920, pp. 249–251, 2 figs. Results of experiments on the absorption of liquids in the kyanizing process.

PORTS

Antwerp. The Port of Antwerp, H. E. Cooper Newham and Clifford Atkinson. Shipping, vol. 12, no. 4, Oct. 25, 1920, pp. 19–27 and 32, 6 figs. Cargo handling machinery and equipment.

Layout of. What the Government is Doing to Help Port Layout, F. T. Chambers. Eng. News-Rec., vol. 85, no. 18, Oct. 28, 1920, pp. 850–851. Shipping act instructs U. S. Shipping Board and Secretary of War to promote port development and transportation facilities in connection therewith. Extent to which this instruction has been carried out is outlined in article. (Abstract.) Paper read before Am. Assn. of Port Authorities.

POWER FACTOR

Improvement of. The Power Factor Problem (Zur Leistungsfaktorfrage), H. Buchholz. Elektrische Kraftbetriebe u. Bahnen, vol. 18, no. 24, Aug. 24, 1920, pp. 201–202, 2 figs. Discussion of measures adopted in Germany, France and especially America for increasing power factor in three-phase current. Notes on installation of synchronous in place of asynchronous motors, phase displacers, tariff regulations; enlightenment of consumers concerning phase displacement through an example from commercial practice.

POWER PLANTS

Automatic Regulation. Automatic Hydraulically Operated Regulating System. Iron Age, vol. 106, no. 19, Nov. 4, 1920, pp. 1185–1187, 4 figs. Arca system for automatic regulation of steam, gas, moisture, temperature, electric current, etc., in use in various industries in Sweden, and being introduced in U. S. by American Galco, Inc., New York City.

POWER TRANSMISSION

Carey Oil System. The Carey Oil Transmission System. Engr., vol. 130, no. 3377, Sept. 17, 1920, p. 284, 2 figs. Machines for transmitting power by means of oil under pressure. Two pumps are used which have balls instead of disks as pistons. Balls are giving reciprocating motion in regard to cylinders by being rotated within eccentric rings.

PRESSWORK

Methods. Press Work in an Electric Motor Plant—I, Fred R. Daniels. Machy. (N.Y.), vol. 27, no. 3, Nov. 1920, pp. 264–269, 15 figs. Methods used in power press department of Gen. Elec. Co., Lynn, Mass.

PROSPECTING

Desert. Desert Prospecting, Leroy A. Palmer. Eng. and Min. Jl., vol. 110, no. 18, Oct. 30, 1920,

tions of dry placers. Occurrence of water.

PUBLIC UTILITIES

Rate of Return. Utility Regulation and Rate of Return, Cecil F. Elmes. Elec. Ry. Jl., vol. 56, no. 16, Oct. 16, 1920, pp. 760–764. It is argued that dual standard of commerce regulation which affects utilities, but exempts other industries, has no justification on historical grounds or as matter of public policy. Effect on financing of utilities analyzed. (Abstract.) Paper read before Am. Elec. Ry. Assn.

PUBLIC WORKS

National Department of. The National Department of Public Works Situation. Eng. News-Rec., vol. 85, no. 18, Oct. 28, 1920, pp. 834–835. Report of M. O. Leighton to Engineering Council states that moral support is needed now to finish legislative program. Engineers' Corps will control unless civilians act, report says.

PULLEYS

Cone. Machining Cone Pulleys, Ralph E. Flanders. Machy. (Lond.), vol. 17, no. 419, Oct. 7, 1920, pp. 11–12, 4 figs. Tooling equipment and methods employed in the quantity production of three and four-step cone pulleys.

PUMPING STATIONS

Gas-Engine-Driven. Gas-Engine-Driven Pumping Plant at the Tilbury Docks. Eng., vol. 110, no. 2860, Oct. 22, 1920, pp. 532–534, 5 figs. Installation for pumping out dry docks for Port of London Authority.

Pump Selection. Well Tests—The Basis for Pump Selection, George M. Shepard. Mun. & County Eng., vol. 59, no. 4, Oct. 1920, pp. 137–138, 1 fig. Diagram showing results of tests on 12-in. well, 380 ft. deep.

PUMPS, CENTRIFUGAL

Tests. Motor-Driven Pumps Develop High Efficiency. Eng. World, vol. 17, no. 5, Nov. 1920, pp. 358–360, 3 figs. Tests on centrifugal pumps direct connected to synchronous motors at McCarren pumping station, Water Department of City of St. Paul, Minn.

R

RADIO COMMUNICATION

Alexanderson's System. Transoceanic Radio Communication, E. F. W. Alexanderson. Gen. Elec. Rev., vol. 23, no. 10, Oct. 1920, pp. 794–803, 12 figs. Description of Alexanderson's system of telegraphic and telephonic radio.

The Alexanderson System for Radio Communication, Elmer E. Bucher. Gen. Elec. Rev., vol. 23, no. 10, Oct. 1920, pp. 813–839, 41 figs. Description is devoted principally to 200-kw. set.

[See also RADIOTELEGRAPHY; RADIOTELEPHONY.]

RADIOTELEGRAPHY

Antennae. A Rule for Antenna Models (Ein Satz über Modelle von Antennen), Max Abraham. Jahrbuch Zeit. für Telegraphie u. Telephonie, vol. 16, no. 1, July 1920, pp. 67–70. Writer evolves a law which, it is claimed, can be used for the qualitative and eventually for quantitative determination of the earth resistance of antennæ.

Abstractive and Selective Properties of Radio Antenna Circuits, Edward Bennett. Jl. Am. Inst. Elec. Engrs., vol. 39, no. 11, Nov. 1920, pp. 995–1004, 7 figs. Consideration of properties of simple series antenna circuit with object of determining circuit proportions and frequencies which will make circuit most highly responsive to correspondent's signal and unresponsive to interference sources.

Coils vs. Antennae. The Use of Coils in Place of Antennæ in Radiotelegraphic Reception (Ueber die Verwendung von Spulen an Stelle von Antennen beim Empfang in der drahtlosen Telegraphie), Herbert Hoffmann. Jahrbuch Zeit. für Telegraphie u. Telephonie, vol. 16, no. 1, July 1920, pp. 31–66, 22 figs. Points out advantages of a receiving apparatus without antennæ, describes qualities of coils, and gives results of experimental tests of the most feasible connections. Recommendations for use of coils in special cases and for radiotelephony. Report from laboratory of the Torpedo Inspection at Kiel.

High-Speed. Service Tests and Experiences with Wireless High-Speed Telegraph (Ueber Betriebsversuche und Erfahrungen mit drahtloser Schnelltelegraphie), Fritz Banneitz. Telegraphen- u. Fernprech-Technik, vol. 9, no. 5–6 Aug. 1920, pp. 90–93, 5 figs. Describes arrangement adopted in connection with installation of a new high-speed network by the Nat. Telegraph Administration; and gives results of high-speed tests with the Wheatstone system carried out by the Wireless Service Bur., Berlin, between Berlin and Stettin and between Berlin and Königsberg, from which it is concluded that, with use of described apparatus, a serviceable high-speed connection can be maintained.

Research. Recent Experimental Work in Radiotelegraphy (Neuere Arbeiten aus dem Gebiete der Funkentelegraphie), F. Kiebitz. Telegraphen- u. Fernsprech-Technik, vol. 9, no. 5–6, Aug. 1920, pp. 88–90, 2 figs. Notes on investigations of of the periods; wireless telephony; measuring methods and investigations of coils; reception by means of writing apparatus; etc. Preliminary report from the Telegraph Testing Bur.

Signaling. A New Arc Method for Continuous Waves. Wireless Age, vol. 8, no. 2, Nov. 1920, p. 19, 3 figs. Method of signaling with arc transmitter.

RADIOTELEPHONY

Receivers. Duplex Radiophone Receiver on U.S.S. George Washington, Harold H. Beverage. Gen. Elec. Rev., vol. 23, no. 10, Oct. 1920, pp. 807–812, 5 figs. In arranging for duplex communication between George Washington and land stations, one of major difficulties encountered was prevention of each receiver from being affected by powerful interference of its own transmitter. Problem was solved by separating transmitting and receiving stations distance of four miles. How this scheme worked out for land stations, was modified on board George Washington is described.

Transmitters. Radiophone Transmitter on the U.S.S. George Washington, John H. Payne. Gen. Elec. Rev., vol. 23, no. 10, Oct. 1920, pp. 804–806, 2 figs. With chart showing names and positions of ships which reported hearing radiophone messages from U.S.S. George Washington.

RAILS

Creep of. Rail Creep. Ry. Engr., vol. 41, no. 489, Oct. 1920, pp. 412–413. Summary of views of prominent engineers on bodily movement of rails in longitudinal direction.

Electric Welding of. See ELECTRIC WELDING, Rails.

Rolling of. Steel Rails from Sink-Head and Ordinary Rail Ingots, George K. Burgess. Chem. & Metallurgical Eng., vol. 23, nos. 19 and 20, Nov. 10 and 17, 1920, pp. 921–925 and 969–975, 8 figs. Nov 10: Experimental investigations of Pennsylvania Railway; Nov. 17: Sink-head ingots are shown to give much more uniform metal than common American types.

RAILWAY CONSTRUCTION

Earth Shrinkage in Fills. Density Tests of Earth Shrinkage in Railway Fills. Eng. News-Rec., vol. 85, no. 17, Oct. 21, 1920, pp. 782–783, 1 fig. Density tests of earth samples made by valuation department of Chicago, Burlington & Quincy Railroad. Density was found to vary according to depth in original excavation.

Shrinkage and Swell of Materials in Railway Fill. Eng. World, vol. 17, no. 5, Nov. 1920, pp. 362–363. Actual measurement taken of many fills. Rock swells, earth shrinks. Carriers' report to Interstate Commerce Commission.

RAILWAY ELECTRIFICATION

Belgium. Railway Electrification in Belgium (Elektrification des chemins de fer de l'état Belge), A. Tétrel. L'Électricien, vol. 51, no. 1261, Oct. 1, 1920, pp. 409–413, 1 fig. Proposed plan.

British. The Electrification of British Railways, Albert H. Bridge. Elec. Rev. (Chicago), vol. 77, no. 18, Oct. 30, 1920, pp. 685–686. Points considered and recommendations made by government committee of engineering and railway experts.

The Electrification of Railways. Elecn., vol. 85, no. 2212, Oct. 8, 1920, p. 421; also editorial comment, pp. 412–413; and also in Ry. Engr. vol. 41, no. 490, Nov. 1920, pp. 453–454 and Tramway & Ry. World, vol. 48, no. 19, Oct. 14, 1920, pp. 226–227. Interim report of Committee appointed by British Ministry of Transport to inquire into certain questions connected with electrification of railways. Committee recommend that future standard system of working electric railways shall be direct current at 1500 volts, but existing 600- and 1200-volt railways may continue in use, their extension being subject to approval of Ministry. (Abstract.)

Japan. Electrifying Japan's State Railways, Ivan F. Baker. Trans-Pacific, vol. 3, no. 5, Nov. 1920, pp. 47–51, 8 figs. Account of progress made, with particular reference to recent projects involving electrification of over 400 miles. Also brief survey of railway electrification developments throughout the world.

RAILWAY OPERATION

Divisional Organization. Railway Operation and Maintenance under Divisional Organization, Alfred Price. Central Ry. Club, Official Proc., vol. 28, no. 3, May 1920, pp. 866–873 and (discussion) pp. 873–894, 1 fig. Scheme of organization of Canadian Pacific Railway.

Increasing Car Service. Increasing the Miles Per Car Per Day, A. G. Smart, J. Burnett, E. H. De-Groot, Jr., F. P. Roesch and A. F. Mercier. Ry. Age, vol. 69, no. 20, Nov. 12, 1920, pp. 824–828. Papers received in contest held by Railway Age on means for increasing the average miles per car per day.

Locomotive Schedules. Economical Operation of Railways (De la reduction du prix de revient dans l'exploitation des chemins de fer), Ulysse Lamalle. Revue universelle des Mines, vol. 7, no. 1, Oct. 1, 1920, pp. 1–45, 7 figs. Organization of service schedule for locomotives.

Supervision. The Problems of the Supervising Officers, Samuel O. Dunn. Ry. Mech. Engr., vol. 94, no. 11, Nov. 1920, pp. 689–691. Their duties

RAILWAY SHOPS

Railroad Shops. Ry. Mech. Engr., vol. 94, no. 11, Nov. 1920, pp. 725–726, 2 figs. It is said important savings are possible by operating brass foundries in conjunction with railroad shops.

Car, N. Y. C. N. Y. C. Steel Car Shop at East Buffalo. Ry. Mech. Engr., vol. 94, no. 11, Nov. 1920, pp. 701–703, 7 figs. Capacity of building is 236 cars.

Tools. Tools from a Railroad Blacksmith Shop, Fred H. Colvin. Am. Mach., vol. 53, no. 18, Oct. 28, 1920, pp. 795–797, 10 figs. Methods of punching, shearing and forming metal.

RAILWAY TIES

Reinforced Concrete. Reinforced Concrete Sleepers—I. Indian Eng., vol. 68, no. 13, Sept. 25, 1920, pp. 179–182. Review of their requirements and their advantages.

Timber. Cross-Tie Forms and Rail Fastenings, with Special Reference to Treated Timbers, Hermann Von Schrenk. U. S. Dept. of Agriculture, Bur. of Forestry, Bull. no. 50, 1904, 71 pp. Possibilities of using substitutes for wood for railway ties are discussed, methods of cutting timber ties are surveyed, and modifications in them are recommended, and specifications and classification of ties are suggested.

RAILWAY TRACK

Catchpoints. The Relative Utility of Catchpoints and Buffer Stops. Ry. Gaz., vol. 33, no. 16, Oct. 15, 1920, pp. 510–514, 11 figs. Results of some Great Western experiments in connection with derailing efficiency of various types of catchpoints, and utility of buffer stops as compared with soft banks.

Materials. On the Question of Special Steels (Subject III for Discussion at the Ninth Congress of the International Railway Association), Mr. Sand. Bul. Int. Ry. Assn., vol. 2, no. 9, Sept. 1920, pp. 563–570. Report on the kinds of special steel used for tracks, in particular for rails, switches, single and double crossings, expansion devices at ends of bridges and other parts of track. Data are based on experiences of railways in various countries.

Standardizing Work. Methods of Standardizing Track Work, Earl Stimson. Official Proc. St. Louis Ry. Club. vol. 25, no. 5, Sept. 23, 1920, pp. 55–67. Experience of Baltimore & Ohio Railroad.

Ties. See RAILS; RAILWAY TIES.

Work Records. New System of Track Work Records on St. L.-S. F. Ry. Eng. News-Rec., vol. 85, no. 20, Nov. 11, 1920, pp. 949–952, 5 figs. Foremen report time and amount of work in detail classification. Figures extended to cover operating divisions.

RAILWAYS

China and the Orient. The Railways of the Orient, Donald F. McLeod. Eng. News-Rec., vol. 85, no. 20, Nov. 11, 1920, pp. 952–955, 2 figs. Rolling stock and construction of roadbed are chiefly of European types. Locomotives and dining and freight cars are mostly of American type.

Location of Industries on Rights-of-Way. Hazards Incident to the Location of Industries on Railroad Right-of-way. Ry. Rev., vol. 67, no. 19, Nov. 6, 1920, pp. 713–715, 1 fig. Discussion of relations between railroads and industries, nature of whose operations are conducive to fire hazard, and forms of agreements that should properly exist between such contracting parties. Paper presented at recent convention of Railway Fire Prevention Association at Baltimore, Md.

REFRIGERATING PLANTS

Ammonia Charge. Behavior of Ammonia in Refrigerating Plants, John H. Ryan. Power, vol. 52, no. 16, Oct. 19, 1920, pp. 613–614, 2 figs. How to find quantity of ammonia necessary to add to charge of running plant.

Electrically Operated. Electrical Refrigeration, C. J. Carlsen. Elec. Jl., vol. 17, no. 11, Nov. 1920, pp. 502–506, 7 figs. Progress in Chicago and suburbs.

Refrigerating Plant at Los Angeles Wholesale Terminal, C. W. Geiger. Power Plant Eng., vol. 24, no. 22, Nov. 15, 1920, pp. 1059–1061, 5 figs. Refrigerating machinery throughout is operated by electric motors, total of 340 hp. of electric motors operating 175 tons of refrigerating machinery.

RELAYS

Reverse-Power Type. Protective Relays-Reverse-Power Type, Victor H. Todd. Power, vol. 52, no. 18, Nov. 2, 1920, pp. 689–692, 10 figs. Conditions produced in system of parallel feeders when short-circuit occurs and types of reverse-power relays that will operate under these conditions. Both single-phase and polyphase relays are treated of.

RESEARCH

Aircraft. The Present Position of Aircraft Research and Contemplated Developments, E. L. Ellington. Flight, vol. 12, no. 44, Oct. 28, 1920, pp. 1130–1132; also in Engineering, vol. 110, nos. 2859 and 2860, Oct. 15 and 22, 1920, pp. 504–505 and 554–555. Directions in which British Air Ministry expect aircraft engines and accessories to develop, and steps they are taking to bring about developments they require. Paper read before Air Conference London, Oct. 13, 1920.

ENGINEERING INDEX (Continued)

is said to effect 27 per cent saving in material and about 40 per cent saving in labor, and to overcome all the defects originating in the welding together of large plate connections.

SHIPS, CONCRETE

Construction. Notes on Concrete Ship Construction, I. B. McDaniel. Tech. Eng. News, vol. 1, no. 7, Nov. 1920, pp. 2–3, 4 figs. Method used at San Francisco Shipbuilding Co. in construction of two 7500-ton tankers for U. S. Shipping Board.

SHOVELS

Rotary. Clère Rotary Shovel (La pelle mécanique rotative Clère), E. Weiss. Nature (Paris), no. 2423, Sept. 11, 1920, pp. 174–176, 5 figs. Shovel resembling paddle wheel operated by steam and provided with accessories for loading loose materials on railway cars and other similar uses.

SILVER METALLURGY

Recovery from Manganese-Silver Ores. Recovery of Silver from Manganese-Silver Ores, Jay A. Carpenter. Eng. & Min. Jl., vol. 110, no. 19, Nov. 6, 1920, pp. 898–902. Chloridizing roasting followed by cyaniding offers considerable promise on material which cannot be treated by less costly processes. Volatilization and recovery by Cottrell process also being developed.

SNOW REMOVAL

Tests. Snow Removal Tests. Public Works, vol. 49, no. 19, Nov. 6, 1920, pp. 427–429, 2 figs. Experimental tests of New York City Street Cleaning Department.

SPARK PLUGS

Sparking Potential. The Sparking Potential of Spark Plugs. Automotive Industries, vol. 43, no. 18, Oct. 28, 1920, pp. 864–865, 1 fig. Tests made by engine sub-committee of British National Advisory Committee for Aeronautics.

The Sparking Voltages Between Spherical Electrodes, Alexander Russell. Jl. Instn. Elec. Engrs., (Supp.), vol. 57, part 2, Oct. 1920, pp. 223–230. Formulæ for maximum electric stress between equal spherical electrodes.

SPRINGS

Spiral. Spiral Springs, P. H. Parr. Mech. World, vol. 68, no. 1762, Oct. 8, 1920, pp. 256–257. Formulæ and tables for designing them.

STANDARDIZATION

Revolutions per Minute. The Standardization of the Number of Revolutions (Ueber die Normalisierung von Drehzahlen), Reinhold Rüdenberg. Betrieb, vol. 2, no. 14, Aug. 1920, pp. 352–357, 4 figs. Recommends establishment of a certain series of standard revolution numbers to which the future construction of machines should be limited.

STANDARDS

German N. D. I. Report. Report of the German Industry Committee on Standards (Mitteilungen des Normenausschusses der Deutschen Industrie). Betrieb, vol. 2, no. 15, Aug. 1920, pp. 373–389, 24 figs. Proposals of the Board of Directors for allowances of standard holes and shafts; machining accuracy of limit gages; cylindrical and conical boring bushes; and disk keys. Proposed standards for determination of hardness according to Brinell's method; set screws and counterborings of splines; and machine-tool handles.

The Standardization of Bores, Wheel Widths and Rounding of Teeth on Change Gears (Normung der Bohrungen, Radbreiten und seitlichen Rundungen an Wechselrädern), H. Toussaint. Betrieb, vol. 2, no. 16, Sept. 1920, pp. 410–411, 2 figs. Report of the working committee for pinions.

Report of the German Industry Committee on Standards (Mitteilungen des Normenausschusses der Deutschen Industrie), Betrieb, vol. 2, no. 16, Sept. 1920, pp. 401–409, 12 figs. Proposals of Board of Directors for snap gages, and soft steel pipes for gases and liquids. Proposed new standards for binding screws and for wrench openings.

Hollow Brick. Hollow Brick Standards (Normen für Hohlziegel), L. Schmelzer. Zielgelwelt, vol. 51, no. 29, July 24, 1920, pp. 325–327, 1 fig. Writer refers to his own and K. Dümmler's recommendations for standards.

STANDPIPES

Concrete. Concrete Standpipe for 110 ft. Head at Kansas City, T. D. Samuel, Jr. Eng. News-Rec., vol. 85, no. 18, Oct. 28, 1920, pp. 841–843, 5 figs. With 40 ft. diameter has capacity of 1,000,000 gallons. Top is 134 ft. above ground. Has joint at base.

STEAM ENGINES

Uniflow. The Uniflow Steam-Engine, F. B. Perry. Jl. Inst. Mech. Engrs., no. 6, Oct. 1920, pp. 731–743 and (discussion) pp. 743–764, 20 figs. History, principle of work and details of construction.

STEAM PIPES

High-Pressure. High-Pressure Steam Lines (Beitrag zum Kapitel Hochdruckdampfleitungen), Eduard Kaschny. Der praktische Maschinen-Konstrukteur, vol. 53, no. 35–36, Sept. 2, 1920, pp. 305–313, 9 figs. Discusses movement of gases in pipe lines according to results of various experiments and describes fittings for modern plants. Schematic diagrams illustrating how plant should be constructed with regard to economy and safety of operation. Calculation of diameter of pipe lines, pressure and heat losses, and insulation are carried out with aid of graphic charts.

STEEL

Arc-Fused. Metallography of Arc-Fused Steel, Henry S. Rawdon, Edward C. Groesbeck and Louis Jordan. Chem. & Metallurgical Eng., vol. 23, no. 16, Oct. 20, 1920, pp. 777–782, 38 figs. Various lines of investigations are utilized to support idea that microscopic "plates" existing in fusion welds are due to nitrogen; that plates are very persistent, and are not responsible for low ductility of metallic piece.

Bars, Specifications. Specifications for Steel Bars for Other Uses than the Manufacture of Machine Tools (Cahier des charges pour la fourniture de barres en aciers au carbone autres que les aciers à outils), Revue de Métallurgie, vol. 17, no. 8, Aug. 1920, pp. 555–560. Adopted by Commission permanente de Standardisation.

Copper, Developments in. A Review of the Development of Copper Steel, D. M. Buck. Iron Age, vol. 106, no. 18, Oct. 28, 1920, pp. 1109–1110. Bibliography of subject. Use of product in steel freight cars. (Abstract.) Paper read before Am. Iron & Steel Inst.

Review of the Development of Copper Steel, D. M. Buck. Blast Furnace & Steel Plant, vol. 8, no. 11, Nov. 1920, p. 593. Discusses results of various researches since 1900 and advises adoption of copper-bearing steel in other sections than sheets. Bibliography of recent literature.

Elastic Strength. Relative Elastic Strengths of Steel. Can. Engr., vol. 39, no. 18, Oct. 28, 1920, pp. 465–468, 1 fig. Relation of elastic strengths in shear, tension and compression. Guest's law is claimed to be erroneous, and it is held that establishment of correct ratios improves design of structural elements subject to combined stresses.

Electric. Electric Steels, C. G. Carlisle. Eng., vol. 110, no. 2857, Oct. 1, 1920, pp. 456–457. Diagram showing relation of cutting speed to durability. (Abstract.) Paper read before Iron & Steel Inst.

Impurities, Detection of. An Electrometric Method for Detecting Segregation of Dissolved Impurities in Steel, E. G. Mahin and R. E. Brewer. Jl. Indus. & Eng. Chem., vol. 12, no 11, Nov. 1920, pp. 1095–1098, 3 figs. Method developed at chemistry laboratory of Purdue University, Lafayette, Ind., for measuring electrode potential of single grain or microscopic point on metal specimen. Application of method to piece of steel containing segregated ring of ferrite, produced by heating in contact with aluminum bronze, developed that average values for ferrite ring were 0.051 volt lower than for ferrite in unaffected body of steel. This was considered indication of different degree of purity for ferrite under two conditions, and theory is advanced to account for ferrite ring.

Inclusions. Inclusions and Ferrite Crystallization in Steel. II—Solubility of Inclusions, E. G. Mahin and E. H. Hartwig. Jl. Indus. & Eng. Chem., vol. 12, no. 11, Nov. 1920, pp. 1090–1095, 3 figs. Alloys and special steels were turned into small rods and driven into holes in carbon steels, and the whole was then heated to temperatures above transformation range for steel. Section of slowly cooled piece showed in nearly all cases, ferrite segregation around insert. Hypothesis to explain phenomenon is advanced and character of influence of nonmetallic inclusions upon ferrite segregation is discussed.

Notched-Bar Tests. Experimental Study on Impact Tests of Notched Bars (Etude expérimentale sur les essais au choc des barreaux entaillés), André Cornu-Thénard. Revue de Métallurgie, vol. 17, no. 8, Aug. 1920, pp. 536–554, 5 figs. Comparative study of machines and processes. (To be continued.)

Open-Hearth, Basic. High Manganese Iron in Basic Open-Hearth Practice, E. A. Wheaton, Iron Age, vol. 106, no. 18, Oct. 28, 1920, pp. 1112–1114. Paper read before Am. Iron & Steel Inst.

Manganese Iron as Desulphurizer, E. A Wheaton. Iron Trade Rev., vol. 67, no. 18, Oct. 28, 1920, pp. 1196–1198. Tests indicate that use of high manganese pig iron enables open-hearth operators to maintain low sulphur content in basic steel. Practice does not reduce tonnage. (Abstract.) Paper read before Am. Iron & Steel Inst.

Making Basic Open-Hearth Steel, F. L. Toy, Iron Trade Rev., vol. 67, nos. 18 and 19, Oct. 28, and Nov. 4, 1920, pp. 1199–1201 and 1275–1277 and (discussion) pp. 1277–1278. Oct. 28: Developments in device and methods for preserving and lengthening life of furnace. Merits of various fuels for melting charges. Efficiency of furnaces; Nov. 4: Working high-sulphur pig iron by use of heavy lime burdens results in an excessive slag volume. Importance of manganese in controlling fluidity and basicity of slag. Pouring temperature discussed. Paper read before Am. Iron & Steel Inst. (Abstract.)

The Basic Open-Hearth Process, F. L. Toy. Iron Age, vol. 106, nos. 18 and 19, Oct. 28 and Nov. 4, 1920, pp. 1116–1119 and 1193–1195. Paper read before Am. Iron & Steel Inst.

Use of High Manganese Iron in Basic Open Hearth Practice, E. A. Wheaton. Blast Furnace & Steel Plant, vol. 8, no. 11, Nov. 1920, pp. 596–598. Paper read before Am. Iron & Steel Inst.

Production in Electric Furnace. Producing Acid Steel Electrically, James W. Galvin and Charles N. Ring. Iron Trade Rev., vol. 67, no. 17, Oct. 21, 1920, pp. 1130–1132. It is held furnace bottoms should be cup instead of saucer shaped. Effect of melting efficiency of degrees of compactness of scrap charged into furnace is studied.

[See also ALLOY STEELS; STEEL, HIGH-SPEED; NICKEL STEEL.]

STEEL CASTINGS

Heat Treatment. Heat Treatment Improves Castings, Fred Grotts. Foundry, vol. 48, no. 21, Nov. 1, 1920, pp. 859–860 and 881, 14 figs. Strength and elongation of cast-steel tractor parts are improved by quench-and-draw treatment. Danger from hardening cracks eliminated by removing castings from water before entirely cool. Paper read before Am. Foundrymen's Assn.

STEEL, HEAT TREATMENT OF

Automobile Steels. The Heat Treatment of Automobile Steels, R. R. Abbott. Iron Age, vol. 106, no. 18, Oct. 28, 1920, pp. 1110–1112, 2 figs. Also Iron Trade Rev., vol. 67, no. 18, Oct. 28, 1920, pp. 1202–1203, 2 figs. Calculation of critical temperatures. Classification of automobile steels. Paper read before Am. Iron & Steel Inst.

Crystalline Structure Produced. Critical Heat Treatment After Critical Cold Working of Low-Carbon Steel (Kritische Wärmebehandlung nach kritischer Kaltformgebung von kohlenstoffarmen Flusseisen), A. Pomp. Stahl u. Eisen, vol. 40, nos. 38, 41 and 42, Sept. 23, Oct. 14 and 21, 1920, pp. 1261–1269, 1366–1378 and 1403–1415, 47 figs. 13 on supp. plate. Based on review of literature, a summary of conditions is given under which coarsely crystalline structure is produced in cold-worked and annealed material. Gives numerical data concerning the changes in the tensile-strength properties due to critical heat treatment after critical cold working, based on experiments described.

Dendritic Formation. Dendritic Steel, H. G. Carter. Trans. Am. Soc. for Steel Treating, vol. 1, no. 1, Oct. 1920, pp. 56–61, 10 figs. It is concluded from results obtained in experiments and microscopic examinations of bars that dendritic steel cannot be broken up structurally, and, therefore, stripping a casting while very hot gives rise to dendritic steel, while if casting is allowed to cool slowly dendrites will be broken up. Hot stripping is condemned as very bad practice.

Electric-Furnace. Heat Treating Steel Electrically, E. F. Collins. Foundry, vol. 48, no. 357, Oct. 15, 1920, pp. 826–830, 12 figs. Test data showing heat uniformity of electric furnace. Paper read before Am. Foundrymen's Assn.

Gas-Fired Furnaces. Hardening Steel in Gas-Fired Furnaces, W. A. Ehlers. Sci. Am., vol. 124, no. 18, Oct. 30, 1920, pp. 450 and 460, 3 figs. Details of furnaces.

Gas vs. Fuel Oil. Producer Gas for Heat Treating, Geo. H. Trout. Trans. Am. Soc. for Steel Treating, vol. 1, no. 1, Oct. 1920, pp. 51–55. Results of comparative tests using fuel oil and gas.

Hardening. Recent Processes for the Hardening of Steel and Iron (Neuere Verfahren zur Härtung von Stahl und Eisen), W. Hacker. Metall-Technik, vol. 36, no. 33–34, Aug. 23, 1920, pp. 129–131. Review of important patents and processes during last few years.

STEEL, HIGH-SPEED

Chromium Determination. The Influence of Vanadium on the Determination of Chromium in High-Speed Tool Steel Containing Tungsten (Einfluss des Vanadins auf die Chrombestimmung in wolframhaltigen Schnelldrehstählen), P. Slawik. Chemiker-Zeitung, vol. 44, no. 103, Aug. 26, 1920, p. 633. Results of experiments are said to show that if certain given directions are carried out, determination of chromium need not be affected by the reddish brown coloring frequently observed in the titration of chromium with iron sulphate.

STEEL INDUSTRY

Europe. European Iron and Steel in 1920, H. Cole Estep. Iron Trade Rev., vol. 67, no. 18, Oct. 28, 1920, pp. 1204–1210, 8 figs. Two years after war England and continental countries with exception of Germany and Russia are regaining prewar capacity. (Abstract.) Paper read before Am. Iron & Steel Inst.

India. India's Steel Industry Expanding, Charles P. Perin. Iron Trade Rev., vol. 67, no. 19, Nov. 4, 1920, pp. 1273–1274. Extension and improvements to blast furnaces and mills will guarantee output of pig iron and steel greater than domestic needs. Country may soon place products in markets of world. (Abstract.) Paper read before Am. Iron & Steel Inst.

The Iron and Steel Industry in India, Charles Page Perin. Iron Age, vol. 106, no. 18, Oct. 28, 1920, pp. 1119–1122, 1 fig. Paper read before Iron & Steel Inst.

South Africa. South African Iron and Steel. Eng., vol. 110, no. 2858, Oct. 8, 1920, pp. 478–480. Possibilities of establishing large iron and steel industry.

Status of. Must Help to Stabilize Business, Elbert H. Gary. Iron Trade Rev., vol. 67, no. 18, Oct. 28, 1920, pp. 1192–1193. Optimistic outlook is made of future developments in steel industry. Tendency, writer says, is towards lower, more reasonable and fairer relative basis. (Abstract.) Presidential address before Am. Iron & Steel Inst.

STEEL MANUFACTURE

Basset Process. Will Exploit New Steelmaking Process, Francis Miltoun. Iron Trade Rev., vol. 67, no. 20, Nov. 11, 1920, pp. 1335. Process for making iron and steel direct from ore using an inclined rotating furnace similar to that employed in manufacture of cement. Process was invented by Lucien Basset and is about to be exploited by French company.

Deoxidizers. New Deoxidizers for Steel Manufacture, J. R. Cain. Chem. & Metallurgical Eng., vol. 23, no. 18, Nov. 3, 1920, pp. 879–882. Report

ENGINEERING INDEX (Continued)

of coöperative investigation sponsored by National Research Council on function and action of deoxidizers, together with experimental work to find low-melting mixtures of scavenging oxides.

[See also ELECTRIC FURNACES, Operating Data; Steel Refining; United Kingdom; IRON METALLURGY, Direct Process.]

STEEL WORKS

Africa. Steel Plants of Africa. Iron Age, vol. 106, no. 20, Nov. 11, 1920, p. 1270. Report on present condition of industry and estimate of requirements.

British. Baldwins, Ltd., Adds New Plant, Joseph Horton. Iron Trade Rev., vol. 67, no. 17, Oct. 21, 1920, pp. 1133–1138, 20 figs. Self contained unit being completed in South Wales district by British steel syndicate. Parent company, capitalized at $35,000,000 controls works in England, Wales and Canada.

Schneider Works, France. The Iron, Steel, and Engineering Works of Messrs. Schneider and Co. Engr. (Supp.), vol. 130, no. 3377, Sept. 17, 1920, 16 pp., 22 figs. Description of chief works of company in France, particularly works at Creusot and Breuil.

The New Steel Works at Breuil (La nouvelle aciérie du Breuil). Génie Civil, vol. 77, no. 15, Oct. 8, 1920, pp. 285–291, 10 figs. partly on supp. plate. Subsidiary to Creusot works. There are eight furnaces, one acid and 7 basic, five of 50- to 60-ton and two of 25- to 30-ton capacities.

Sheet Mills. Material Handling Equipment is Important Factor in New Sheet Mill, E. L. Shaner. Iron Trade Rev., vol. 67, no. 19, Nov. 4, 1920, pp. 1266–1270, 9 figs. Automatic charging machines for sheet and annealing furnaces, crane equipment and electric tractor and trailer system, at works of Newton Steel Co.

STOKERS

Coking. The "Bennis" Patent Coking Stoker. Practical Engr., vol. 62, no. 1755, Oct. 14, 1920, pp. 250–253, 2 figs. Fuel is fed in bulk at front of moving grate, coking taking place and volatile portions being distilled off, while burning mass is gradually conveyed by mechanical means towards rear of grate.

Forced-Draft. Stowe Forced-Draft Stoker. Power, vol. 52, no. 16, Oct. 19, 1920, pp. 624–626, 5 figs. Type developed by Laclede-Christy Clay Products Co., St. Louis, Mo. It consists of traveling chain-grate elements alternating with stationary tuyères.

STREET RAILWAYS

Cars, Safety. One-Man Safety Car Meeting Approval on Many Canadian Systems. Elec. News, vol. 29, no. 21, Nov. 1, 1920, pp. 41–46, 5 figs. Thirteen towns and cities are operating them wholly or in part. It is said that platform expenses have reduced, accidents are almost unknown, schedule is maintained, and service is satisfactory.

Kansas City, Mo. Rerouting Plan to Save $620,000. Elec. Ry. Jl., vol. 56, no. 19, Nov. 6, 1920, pp. 957–961, 6 figs. Report of consulting engineer on Kansas City railways.

Pavement and Construction. Why Street Railways Should Bear Share of Pavement Cost. Eng. News-Rec., vol. 85, no. 17, Oct. 21, 1920, pp. 795–796. Brief of data from 166 cities gives reasons why two-foot strip outside rails should not be diminished.

Regenerative vs. Pneumatic Braking. Street Railway Braking (Beitrag zur Frage der Strassenbahnbremsen), W. Pforr. Elektrische Kraftbetriebe u. Bahnen, vol. 18, no. 12, Apr. 24, 1920, pp. 105–108. Refers to articles appearing in preceding volume of same journal on the relative merits of the purely electric brake and the pneumatic brake with regard to efficiency, safety and economy; and presents table giving operating data of the Buenos Aires (Argentine) street railway during the years 1911–1918, collected and compiled by author, demonstrating the satisfactory use of the short-circuit brake.

Track Deformations. The Deformation of Street Railway Tracks Under Rolling Loads (Die Formänderungen des Strassenbahngleises unter der rollenden Last), H. Bloss. Elektrische Kraftbetriebe u. Bahnen, vol. 18, nos. 10 and 11, Apr. 4 and 14, 1920, pp. 81–85 and 93–97, 21 figs. Account of measurements carried out by author in 1913, with description of measuring method and apparatus employed. Notes on deflection of rail and coefficient of ballast; and the internal deformations of track.

Zone Fares. How the Zone Fare Has Made Good at San Diego. Elec. Ry. Jl., vol. 56, no. 20, Nov. 13, 1920, pp. 1009–1012, 5 figs. In spite of low density of population, high mileage of track, large number of private automobiles and decrease in military and naval population, company shows 40 per cent more revenue and 12 per cent more passengers for first nine months of 1920 as against same period of 1919.

SUBMARINE WARFARE

Detection of Submarines. Modern Marine Problems in War and Peace, C. V. Drysdale. Eng., vol. 110, nos. 2858, 2859 and 2860, Oct. 8, 15 and 22, 1920, pp. 484–486, 6 figs., 521–523, 9 figs., and 552–554, 4 figs. Eleventh Kelvin lecture delivered before Instn. Elec. Engrs.

SUBMARINES

Periscopes. The Construction of U-Boats at the Germania Shipyards (Der Bau von Unterseebooten auf der Germaniawerft), H. Techel. Zeit. des Vereines deutcher Ingenieure, vol. 64, no. 43, Oct. 23, 1920, pp. 882–888, 36 figs. Notes on periscopes, with details of various types, including the multiocular, the panorama and zenith periscope. Describes latest development by the C. P. Goerz Corp., the upright periscope, which differs from previous models in that it consists of two tubes, the ocular and objective, and can be rolled in and out without the observer having to change his position according to the height. (Continuation of serial.)

SUBWAYS

Berlin. The Construction of the Berlin Elevated and Subway Line Through Built-Up Sections of the City (Führung der Berliner Hoch- und Untergrundbahnen durch bebaute Viertel). Verkehrstechnik, vol. 37, no. 25, Sept. 5, 1920, pp. 345–350, 15 figs. Describes, among other things, the building of tunnels under existing buildings without interrupting or interfering with their use for office or living purposes. Details of new section under construction in which line is constructed partly as elevated, through a row of buildings and courts, not as open track, but entirely enclosed with walls and roof in order to protect neighboring houses from noise and sight of railway. Abstract of book by P. Wittig, Director of Elevated & Subway Co., Berlin.

New York City. Rapid Transit Plan for New York Proposes 830 miles of New Track. Eng. News-Rec., vol. 85, no. 16, Oct. 14, 1920, pp. 754–757, 1 fig. Report of chief engineer of Transit Construction Committee. Twenty-one subaqeous tunnels and three moving platforms are recommended.

Stations. A Study of Rapid Transit Station Design, Olof A. Nilsson. Eng. News-Rec., vol. 85, nos. 18 and 19, Oct. 28 and Nov. 4, 1920, pp. 824–829, 12 figs., and 894–899, 11 figs. Possibilities for great time saving in platform arrangement. Nov. 4: Good and bad features in arrangement of platforms and street approaches. Dimensions and capacities that have been found satisfactory.

SULPHURIC ACID

Addition Compounds. The Formation of Addition Compounds Between 100% Sulfuric Acid and the Neutral Sulfates of the Alkali Metals, James Kendall and Mary Louise Landon. Jl. Am. Chem. Soc., vol. 42, no. 11, Nov. 1920, pp. 2131–2142, 2 figs. Experimental investigations of means of freezing-point method upon compound formation in systems containing sulphuric acid and anhydrous neutral sulphates of potassium, ammonium, sodium and lithium from eutectic point of each system up to temperature of 300 deg. cent.

Concentration. The Concentration of Sulphuric Acid, S. J. Tungay. Chem. Age (Lond.), vol. 3, no. 70, Oct. 16, 1920, pp. 416–417, 2 figs. Describes more important systems of concentration, and discusses their relative merits as regards durability, economy of working, fuel consumption, and general efficiency.

T

TAPS

Square and Acme Thread. The Design of Square and Acme Thread Taps of Steep Lead, E. A. Dixie. Am. Mach., vol. 53, no. 20, Nov. 11, 1920, pp. 887–888, 7 figs. Methods of manufacture.

TAR

Removal from Coke Gas. Removing Tar from Coke Gas—V, A. Thau. Iron Trade Rev., vol. 67, no. 20, Nov. 11, 1920, pp. 1331–1335, 10 figs. Rotary tar extractors.

TELEGRAPHY

Research. Report on the Activity of the Telegraph Testing Bureau in the Years 1913–1918 (Bericht über die Tätigkeit des Telegraphen-Versuchsamts in den Jahren 1913–1918). Telegraphen- u. Fernsprech-Technik, vol. 9, no. 5–6, Aug. 1920, pp. 69–85, 11 figs. Report of experimental results of investigations of the dielectric properties of different insulating materials, etc.; the closure of currents; lines and wirings; the technique of telegraphy and telephony; wireless telegraphy; disturbances due to strong current; apparatus; problems of illumination; etc.

TELEPHONY

Automatic. Automatic Telephone Progress. Elecn., vol. 85, no. 2214, Oct. 22, 1920, pp. 466–471, 8 figs. Introduction of panel automatic system into City of London.

High-Frequency. High-Frequency Telephony in Long-Distance Stations (Hochfrequenztelephonie in Ueberlandzentralen), H. Gewecke. Elektrotechnische Zeitschrift, vol. 41, no. 34, Aug. 26, 1920, pp. 670–672, 4 figs. Experiments show that even in the case of serious disturbances in the wiring system, the radio communication can be maintained. Description of first radiotelephonic connection constructed by the Radiotelegraphy Co., Ltd., along the 135-km. high-frequency line Golpa-Rummelsburg, and discussion of relative costs of telephone systems with and without wire.

London System. The Telephone Service of Large Cities, with Special Reference to London, E. A. Laidlaw and W. H. Grinsted. Jl. Instn. Elec. Engrs. (Supp.), vol. 57, part 2, Oct. 1920, pp. 158–188 and (discussion) pp. 188–201, 14 figs. Proposal is made for introduction of "unit of telephone service" as basis of charge made to subscriber. Duration of conversation determines charge.

TELESTEREOGRAPHY

Belin System. Sending Photographs Over Wires, Austin C. Lescarboura. Sci. Am., vol. 123, no. 19, Nov. 6, 1920, pp. 474–483–484, 3 figs. Belin system for sending actual photographs over ordinary telegraph wire. Photograph is received on sensitized cylinder. Quivering ray of light, originated by electric current from transmitter, operates at receiving end successively upon all parts of a sensitized paper cylinder, intensity of light varying so as to reproduce photograph.

TERMINALS, MARINE

Portland, Ore. Port Terminal Pier Design at Portland, Ore., G. B. Hegardt. Eng. News-Rec., vol. 85, no. 17, Oct. 21, 1920, pp. 796–797, 1 fig. Considerations which led to adoption of wide piers and handling machinery in new municipal docks.

TERMINALS, RAILWAY

Design. The Grouping of the Rail Lines in Terminal Stations with Through Passage for Trains (Ueber die Gruppierung der Geleise bei Kopfbahnhöfen), Rob. Findeis. Schweizerische Bauzeitung, vol. 76, nos. 14 and 15, Oct. 2 and 9, 1920, pp. 153–155 and 165–167, 10 figs. Theoretical study of possible line arrangements, inspired by the expert testimony of Cauer, Moser and Gleim, relative to the proposed extension of the Zürich main railroad station.

TESTING MACHINES

Transverse Tests on Cast Iron. Develops New Machine for Bending Tests. Iron Trade Rev., vol. 67, no. 17, Oct. 21, 1920, pp. 1139–1140, 1 fig. Hand-operated transverse and bend testing machine actuated by oil pressure. Developed by Alfred J. Amsler & Co., Switzerland.

THERMOCOUPLES

Junctions. The Construction of Thermocouples by Electro-Deposition, Wm. Hamilton Wilson and Miss T. D. Epps. Physical Soc. of London, Proc., vol. 32, part 5, Aug. 15, 1920, pp. 326–340, 15 figs. Method devised to overcome difficulty of making satisfactory soldered joints between elements of thermopiles having large number of closely packed junctions, consists in using continuous wire of one of elements and coating those parts of it which have to form other element with electrolytic deposit of another metal.

THERMOMETERS

Mercury, Standardization of. Standardization of Mercury Thermometers (Normalissierung von Quecksilberthermometern), H. Siebert and Karl Scheel. Zeit. für angewandte Chemie, vol. 33, no. 73, Sept. 10, 1920, p. 216. Recommendations for standardization of ordinary thermometers and the Allihn and Anschütz composition thermometers.

TIDAL POWER

Utilization. Utilization of the Tides (Utilisation des marées) Amiral Amet. Revue générale de l'Électricité, vol. 8, nos. 14 and 15, Oct. 2 and 9, 1920, pp. 445–455, and 483–492, 15 figs. General theory. Coördination of available data. (To be continued.)

TOOLS

Steel, High-Speed. High-Speed Cast Steel Tools from the Electric Furnace, Sterling H. Bunnell. Iron Age, vol. 106, no. 20, Nov. 11, 1920, pp. 1258–1259, 3 figs. Practice of United States High-Speed Steel & Tool Corporation in making tools ready for use in any desired shape.

TOWN PLANNING

France. Reconstruction Progress and City Planning in France, George B. Ford. Eng. & Contracting, vol. 54, no. 17, Oct. 27, 1920, pp. 421–422. Compulsory city planning law in France. Paper read before Am. Soc. for Mun. Improvements.

TRACTORS

Castings. Heat Treating Tractor Castings, Fred Grotts. Iron Trade Rev., vol. 67, no. 20, Nov. 11, 1920, pp. 1346–1348, 12 figs. Research work conducted by Holt Mfg. Co., Peoria, Ill. (Abstract.) Paper read before Am. Foundrymen's Assn.

Manufacture. Operations in Building Tractors. Fred H. Colvin. Am. Mach., vol. 53, no. 20, Nov. 11, 1920, pp. 877–883, 25 figs. Methods at works of C. L. Best Gas Traction Co., California.

Tests. Tractors at the Royal Agricultural Society's Trials at Lincoln. Eng., vol. 110, no. 2858, Oct. 8, 1920, pp. 472–474, 476 and 481–482, 10 figs. Particulars of competing tractors and account of trials.

Tractors Perform Effectively in British Trials, M. W. Bourdon. Automotive Industries, vol. 43, no. 18, Oct. 28, 1920, pp. 856–860, 16 figs. Account of 1920 British tractor trials. There were 46 entries all except two of which were powered by internal-combustion engines.

TRAIN CONTROL

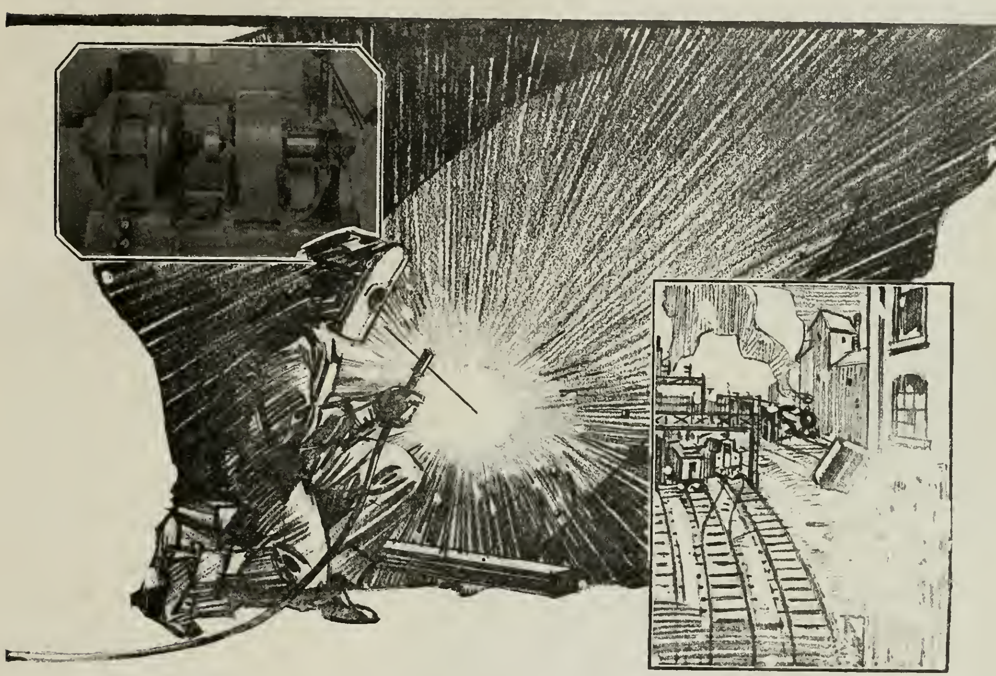
Automatic. Test of Shadle Automatic Train Control. Ry. Signal Engr., vol. 13, no. 10, Oct. 1920, pp. 404–405, 1 fig. Chart showing signal indications for each run as train approaches.

Intermittent-Contact Type. The Bourdette-Brookins Train Control System. Ry. Signal Engr., vol. 13, no. 10, Oct. 1920, pp. 411–413, 7 figs. System is of intermittent electrical contact type.

TRAIN LIGHTING

Lamps for. Essentials of Train Lighting. Bul. Eng. Dept. Nat. Lamp Works, Gen. Elec. Co., bul. no. 10D, Oct. 27, 1919, 16 pp., 13 figs. Sug-

Sometimes the producer is so absorbed with the task of producing, that he overlooks means which might make his plant more productive



A Welded Seam with All the Strength of the Original Metal

Full of oil and sealed tight a tank was dropped from a four-story building onto a railroad track, and nothing but a dent in the tank! A real test of strength, and yet the electric arc welded seam did not leak or show a sign of weakness. Electric welding makes every seam a part of the product itself, rather than a connection which merely holds it together.

In every industry wherever metals are joined together, the electric weld is stronger, more durable, and permits special construction and more efficient design of parts than is possible with bolts and rivets. Its uses are so varied that in places where it is installed for a certain purpose, it soon develops a greater usefulness as men become more familiar with its operation.

To make electric arc welding a real factor in production, the General Electric Company has developed arc welding equipment for almost every purpose, large and small, suitable for factories where there is enough welding to keep one or many men busy.

Whether your welding problems require a small portable set or a large stationary outfit, the knowledge and experience of G-E specialists and their co-operation are available for the asking.

Select the right equipment for the work—and a welder who knows his business

Bulletins describing G-E Welding Equipment and the G-E Welding School sent on request to our nearest office

ENGINEERING INDEX (Continued)

gestions as to proper use of Mazda lamps for train lighting. Technical data of lamps.

TRANSPORTATION

Land vs. Water Routes. Comparison of Cargo Transportation by Land and Water Routes, William T. Donnelly. Marine Eng., vol. 25, no. 11, Nov. 1920, pp. 899–803, 5 figs. System for prompt dispatch of cargoes by inland water routes. Fleets of separately propelled vessels travel together in convoy with central electric generating station afloat connected to fleet by cable and with all propellers driven by electric motors. Such a system is found to be more economical than any of land systems.

Steam Vehicles. Road Transportation by Steam-Vehicles, P. W. Robson. Jl. Instn. Mech. Engrs., no. 6, Oct. 1920, pp. 639–661 and (discussion) pp. 661–672, 9 figs. Sees steam motor wagon "as the most economical and reliable form of road transport."

TUBES

Manufacture. Manufacturing Steel and Iron Tubes, H. C. Ebright. Blast Furnace & Steel Plant, vol. 8, no. 11, Nov. 1920, pp. 609–612, 3 figs. Youngstown sheet and Tube Company's method of manufacturing pipe processes used in forming and welding steel tubes. Process of threading, testing and finishing.

Narrow, Riveting. Riveting of Narrow Tubes. Eng. and Indus. Management, vol. 4, no. 15, Oct. 7, 1920, pp. 456–457, 18 figs. Method of riveting narrow tubes from inside. Translated from Luftfahrt, and circulated by British Air Ministry.

TUNNELS

Construction Methods. Tunnels—XXVI. Ry. Engr., vol. 41, no. 489, Oct. 1920, pp. 426–430, 11 figs. Construction methods adopted in Rogers Pass tunnel made by Canadian Pacific Railway in 1913–1915 in British Columbia, and at Twin Peaks tunnel, provided for new highway near San Francisco, Cal.

TURBO-GENERATORS

Small. Small Steam Turbines (Kleindampfturbinen), Werner Bergs. Prometheus, vol. 31, nos. 49 and 50, Sept. 4 and 11, 1920, pp. 385–387 and 395–398, 8 figs. Describes construction by Brown-Boveri & Co. Corp., Mannheim, of small direct-current turbine group for lighting purposes; output: 500 watt, 110 volt, speed 4500 r.p.h.; length, 530 mm.; width, 280 mm.; height, 360 mm.; weight, 75 kg. Details of other BBC small steam turbines for output of 20 to 100 kw., 100 to 500 kw., etc. Points out advantages of small steam turbines in comparison to piston steam engines of the same capacity.

Steel Foundations for. Steel Foundations for 30,000-Kilowatt Horizontal Turbo-Generators, J. R. James. Power, vol. 52, no. 17, Oct. 26, 1920, pp. 646–649, 3 figs. Steel foundations for 30,000-kw. turbo-generators recently installed by Detroit Edison Co. Reduction in weight of about 500 tons was effected, difference in cost was negligible and operation has shown almost no perceptible vibration.

TURPENTINE

Data on. Turpentine: Its Sources, Properties, Uses, Transportation, and Marketing, with Recommended Specifications, F. P. Veitch and V. E. Grotlisch. U. S. Dept. Agriculture, bul. no. 898, Nov. 8, 1920, 51 pp., 7 figs.

V

VACUUM TUBES

See ELECTRON TUBES.

VAPOR PRESSURES

Measurement of. A Method of Measuring Low Vapor Pressures, with Its Application to the Case of Trinitro-Toluene, Alan W. C. Menzies Jl. Am. Chem. Soc., vol. 42, no. 11, Nov. 1920, pp. 2218–2221. Method is outlined by which low vapor pressures may be measured with single McLeod gage.

VENTILATION

Ventilators. Recent Tests on Automatic Ventilators, A. J. Mack. Heat. and Vent. Mag., vol. 17, no. 10, Oct. 1920, pp. 27–29, 3 figs. Results of tests indicated that siphoning ventilators have advantage over non-siphoning types.

[See also HEATING AND VENTILATION.]

VOCATIONAL EDUCATION

Psychotechnical Tests. Fundamental Principles of the Psychotechnical Examination of Industrial Students (Grundsätze der psychotechnischen Lehrlingsprüfung), W. Moede. Werkstattstechnik, vol. 14, no. 16, Aug. 15, 1920, pp. 433–441, 14 figs. Notes on adaptability tests of students and success of such tests at the psychotechnical laboratory of the Charlottenburg High School.

VOLTAGE REGULATION

Step Induction Regulator. The Step Induction Regulator, E. E. Lehr. Elec. Jl., vol. 17, no. 11, Nov. 1920, pp. 510–514, 4 figs. Structural details of apparatus and method of connecting it.

VULCANIZATION

New Process. The New Process for the Vulcanization of Rubber, S. J. Peachy. India Rubber Jl., vol. 60, no. 17, Oct. 23, 1920, pp. 25–26. Cold cure process. It consists in exposing rubber, alone or in admixture with practically any useful filling agent or pigment, successively to action of two gases, sulphur dioxide and hydrogen sulphide. Gases diffuse into rubber and there interacting produce active form of sulphur which is capable of combining with and vulcanizing rubber at ordinary temperature.

W

WAGES

Minimum. Food Requirements and the Minimum Wage. Nature (Lond.), vol. 106, no. 2661, Oct. 28, 1920, pp. 284–286. Based on figures compiled by Food Committee of Royal Society.

WALLS

Concrete. A New System of Hollow Concrete Wall Construction, Charles Alma Byers. Building Age, vol. 42, no. 11, Nov. 1920, pp. 31–32, 3 figs. System designed and patented by Charles B. Harp, construction engineer of Los Angeles, California. Walls are erected with pre-cast concrete slabs which are set edgewise in two tiers to form continuous air space.

WARSHIPS

Cruisers. The Light Cruiser Raleigh. Engr., vol. 130, no. 3381, Oct. 15, 1920, pp. 374–375, 1 fig. Characteristics: Length overall, 605 ft.; extreme breadth, 65 ft.; mean draft, $17^1/_4$ ft.; displacement, 9750 tons; horsepower, 70,000; speed, 31 knots; armament, seven $7^1/_2$-in. and twelve 12-pdr. guns, and six torpedo tubes.

Ex-German. The Ex-German Battleship Baden. Engr., vol. 130, no. 3379, Oct. 1, 1920, pp. 319–322, 13 figs. partly on supp. plate. Structural details.

Superdestroyers. The "Super-Destroyer," Hector C. Bywater. Sci. Am., vol. 123, no. 19, Nov. 6, 1920, pp. 472 and 482, 2 figs. Functions of flotilla leader as contained in recommendations made by General Board of U. S Navy for building program of 1921.

WATER FILTRATION

Research. The Rapid Filtration of Water, Alexander C. Houston. Engr., vol. 130, no. 3375, Sept. 3, 1920, pp. 218–220, 3 figs. Thirteenth Research Report issued by director of Water Examination of Metropolitan Water Board, London. It is principally concerned with question of how far rapid filtration of stored river water is capable of producing supplies which are safe and suitable for human consumption.

WATER HAMMER

Metallic Conduits under Pressure. Study of Water Hammer in Metal Conduits under Pressure (L'étude des coups de bélier dans les canalisations métalliques sous pression), C. Camichel and D. Eydoux. Houille Blanche, vol. 19, no. 43–44, July-Aug. 1920, pp. 127–131, 3 figs. Formulæ for determining velocity of transmission, pressure exerted, etc., and graphs indicating transmission of water hammer. (Continuation of serial.)

WATER GAS

Automatic Controller. Ensuring a Constant Quality of Water Gas. Gas World, vol. 73, no. 1891, Oct. 16, 1920, pp. 297–298, 1 fig. Automatic controller manufactured by Davison and Partner, London, England.

WATER METERS

Design. Defects in Current Meters and a New Design, Samuel Fortier and E. J. Hoff. Eng. News-Rec., vol. 85, no. 20, Nov. 11, 1920, pp. 923–924, 2 figs. Meter developed to meet requirements of relatively low velocities and small channels.

WATER POWER

Federal Power Commission. Commission Drafts Its Rules. Bul. Water Power League of America, vol. 1, no. 2, Aug. 1920, pp. 9–14. Rules and regulations which will govern work of Federal Power Commission created under Federal Water Power Act.

Palestine. Production of Electricity in Palestine by Utilizing Water of Mediterranean Sea (L'elettrificazione della Palestina), A. Gradenwitz. Industria, vol. 34, no. 10, May 31, 1920, pp. 270–271, 2 figs. Level of Mediterranean is 1297 ft. above that of Dead Sea. Their nearest distance apart is less than 43 miles. A tunnel along this line is proposed.

Resources in U. S. Development of National Water-Power Resources, C. D. Wagoner. Elec. Rev. (Chicago), vol. 77, no. 19, Nov. 6, 1920, pp. 717–720, 3 figs. Analysis of developed and undeveloped water powers in U. S.

South America. Electrical Possibilities in South America, Verne Leroy Havens. Elec. World, vol. 76, no. 15, Oct. 9, 1920, pp. 729–730. Opportunities for water power development. Operating difficulties and how they are overcome.

United States. Potential Water Powers. Bul. Water Power League of America, vol. 1, no. 1, July, 1920, pp. 5–6 and 24. Total possible water developments on the 4325 miles of river channels included in present navigation projects over which Federal Government retains jurisdiction for navigation purposes, are estimated to amount to at least 10,200,000 hp.

WATER SUPPLY

Cleveland. Planning the Future of the Cleveland Water Supply, A. V. Ruggles. Eng. News-Rec., vol. 85, no. 19, Nov. 4, 1920, pp. 886–889, 4 figs. Methods followed lead to $30,000,000 program by 1940 delivering 430,000,000 gallons daily from four intakes of which two will be new.

WATER WORKS

Cost-Plus Contracts. Cost-Plus Contracts for Water Works Construction, George W. Fuller. Jl. Am. Water Works Assn., vol. 7, no. 5, Sept. 1920, pp. 683–692. It is held that cost plus contracts, with proper provision for accounting and suprvision, may be satisfactory where conditions are not definitely known and in case of private corporations where well qualified contractors may be selected to work under adequate supervision. Under war conditions, it is said, cost-plus contracts were necessary and even now have many advantages.

WATERWAYS, INLAND

Reconstruction. The Reconstruction of French Inland Waterways (Pour la reconstruction de notre réseau navigable), J. Bondet. Vie Technique & Industrielle, vol. 1, no. 12, Sept. 1920, pp. 463–472, 7 figs. Method of "isolated sections" for reconstructing waterway without interrupting traffic. Special portable dams are firmly placed about 600 ft. apart; water is pumped out from section thus isolated and work required performed over night. Method was invented by Enterprise Fougerolle and is said to have been applied successfully by them in various enterprises.

WAVE POWER

Wave-Motion Turbine. Wave-Motion Turbine, Arthur Palme. Power, vol. 52, no. 18, Nov. 2, 1920, pp. 700–701, 4 figs. Scheme for utilization of wave motion, in operation for some time at Royan, France.

WELDING

Steel, High-Speed. The Welding and Brazing of High-Speed Tool Steel with Carbon-Steel (Verschweissen und Verlöten von Schnelldrehstahl mit Kohlenstoffstahl), Rudolf Schäfer. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 43, no. 32, Aug. 6, 1920, pp. 241–244, 6 figs. Sets forth relative merits of welding and brazing It is shown by numerous examples that a perfect adhesion of high-speed tool steel points to carbon-steel shanks can be effected by welding or brazing and that the electric welding process is most advantageous.

[See also AUTOGENOUS WELDING; ELECTRIC WELDING; ELECTRIC WELDING, Arc; ELECTRIC WELDING, Resistance; OXY-ACETYLENE WELDING.]

WELDS

Tests. Testing Steel Plate Welds. Iron Age, vol. 106, no. 20, Nov. 11, 1920, p. 1265. Methods for quickly determining general character of work. (Abstract.) Paper read before Am. Welding Soc.

Testing Welds, S. W. Miller. Acetylene Jl., vol. 22, no. 5, Nov. 1920, pp. 258–263 and p. 295, 26 figs. Also Welding Engr., vol. 5, no. 10, Oct. 1920, pp. 26–36, 26 figs. Methods of testing. Paper read before Am. Welding Soc.

WIND TUNNELS

Germany. Report on German Wind Tunnels and Apparatus, Edward P. Warner. Aerial Age, vol. 12, no. 10, Nov. 15, 1920, pp. 275–277, 2 figs. Description of wind tunnels at Göttingen, Aachen, Dessau and Friedrichshafen together with methods of operation and details of apparatus used. (To be continued.) Report of Nat. Advisory Committee for Aeronautics.

Resistance Equation. Air Forces on Circular Cylinders, Axes Normal to the Wind, with Special Reference to Dynamical Similarity, Hugh L. Dryden. Sci. Papers, Bur. of Standards, no. 394, Sept. 4, 1920, pp. 489–519, 10 figs. Experimental study of general wind tunnel resistance equation.

WIRING

Earthing. Earthing. Jl. Instn. Elec. Engrs., vol. 58, no. 292, June 1920, pp. 468–475 and (discussion) pp. 476–490, 4 figs. Report of earthing sub-committee of Wiring Rules Committee, appointed to "consider the whole question of earthing, including the time element of circuit-breakers, the heating of conductors, the current-carrying capacity of the apparatus earthed, the drop of pressure in metal sheathing, and the number of earth wires required."

WOMEN WORKERS

Management of Women. The New Place of Women in Industry—II, Ida M. Tarbell. Indus. Management, vol. 60, no. 5, Nov. 1920, pp. 329–330. Discusses successful utilization of women workers.

WOOD PRESERVATION

Charring. Charring Does not Preserve Wood. Forest Products Laboratory, Technical Notes, Oct. 15, 1920, no. 108, 1 p. Tests showed that charring deep enough to resist decay would undoubtedly weaken post of ordinary size.

Preservative Treatment. Water Solubility a Necessary Property of Wood Preservatives. Forest Products Laboratory, Technical Notes, Oct. 15, 1920, no. 114, 1 p. That any substance to be effective wood preservative must be soluble in water at least to extent of producing toxic water solution is basis of theory now being developed at U. S. Forest Products Laboratory.

MECHANICAL ENGINEERING

Volume 43 February, 1921 Number 2

Engineering in the Woodworking Industries

A Group of Papers Presented at the Annual Meeting of the A.S.M.E. Dealing with Furniture Manufacture, Freight-Car Construction, Machining of Railroad Cross-Ties, Wood-Block Floors, Wood Preservation, and Electrically Driven Sawmills

ONE of the most enthusiastic sessions held during the last Annual Meeting of The American Society of Mechanical Engineers was that on Forest Products, under the auspices of the newly formed Committee on Woodworking composed of Thomas D. Perry, Chairman, C. E. Paul, and Grant B. Shipley. As a result of the interest aroused by the session a petition was addressed to the A.S.M.E. Committee on Professional Sections requesting the formation of a Forest Products Section which might coöperate with similar organizations to the mutual benefit of the various woodworking industries.

As a general introduction to the session Frederick F. Murray, director of the department of mechanical engineering of the staff of *Lumber*, presented a strikingly interesting photographic study of the methods employed in logging and in the manufacture of lumber. This covered in brief form the various steps in logging and in the production of lumber at the mill. He also touched upon the utilization of wood waste. A selection of the photographs shown by Mr. Murray, tracing the steps of production from the cutting of the tree in the forest to the storing of the finished product in the lumber yard at the mill, ready for shipment, is given on this and succeeding pages in Figs. 1–27.

Following Mr. Murray's study the six papers scheduled for the session were presented. The first of these papers, Engineering in Furniture Factories, by B. A. Parks, pointed out some of the influences which have militated against the development of the woodworking industry and discussed the general principles involved in the design and layout of a new furniture-manufacturing plant. The Use of Wood in Freight-Car Construction, by H. S. Sackett, considered the relative values of steel and wood as materials for the construction of freight cars. Machining Railroad Cross-Ties, by D. W. Edwards, described the machines employed and processes followed in the machining of ties by trimming, adzing, boring and branding. Creosoted Wood-Block Factory Floors, by Lambert T. Ericson, described methods which will permit engineers to specify and build creosoted wood-block floors without entailing any risk of their failure. Processes and Equipment Used in Wood Preservation, by E. S. Park, dealt briefly with the different processes of pressure treatment. Electrically Driven Sawmills, by Allan E. Hall, set forth the advantages of motor-driven mills. Abstracts of all of these papers follow.

ENGINEERING IN FURNITURE FACTORIES

By B. A. Parks,[1] Grand Rapids, Mich.

THE woodworking industry is one of the oldest industries extant, and yet it has shown the least development and has been the slowest to adopt modern principles of manufacturing of any industry of which the writer has knowledge. There are several causes for this condition, the most important of which are the general lack of accurate cost data and the absence of technically trained men in the executive positions.

In several plants which have come under the writer's notice, only such repairs have been made as were necessary to avoid actual breakdowns, and machinery, power-plant equipment, lighting, heating, drying, sanitary facilities, etc., have been entirely inadequate and inefficient and would not be tolerated in even the average modern plant of most other industries. Also in the several woodworking and furniture-manufacturing plant organizations that have come under the writer's observation, he does not recall a single man with a technical education or training.

This lack of engineering ability in the furniture-manufacturing organization shows its effect throughout the entire plant; in fact, the writer is convinced that the average manager of a furniture plant is more interested in marketing his product than in manufacturing it.

The efficiency of any general plan for a furniture-manufacturing plant, or in fact any industrial plant, may be measured by the degree in which the following requirements are fulfilled:

(*a*) Provision for proper arrangement of the necessary machinery

[1] Mechanical Engineer, Byron E. Parks & Son, Assoc.-Mem.Am.Soc.M.E.

(b) Provision for receiving, handling, storing, and transporting material

(c) Provision for extending the plant and increasing manufacturing facilities without serious disturbance to the original plant or manufacturing routes

(d) Provision for generation and transmission of power, light and heat

(e) Provision for fire protection

(f) Provision for comfort and accommodation of employees.

Location

The importance of the location and arrangement of a furniture factory has not generally received the attention their economic value should dictate. The furniture industry, the same as other industries, has tended to concentrate in given localities, as, for example, Grand Rapids, Mich. This concentration was originally due to nearness to the raw-material supply. As the number of plants multiplied a good supply of skilled labor has accumulated, so that now, even when Grand Rapids is not so well situated as other centers as regards nearness to raw-material supply, the labor market as well as a certain reputation attaching to Grand Rapids product has tended to increase the number of furniture-manufacturing plants in spite of the fact that, theoretically at least, other centers would be more desirable from most standpoints. In general, however, the location of a furniture plant, as for most other types of manufacturing, will be dependent on the following considerations:

(a) Transportation facilities for both raw material and finished product

(b) Availability of raw materials and manufactured parts obtained from other industries

(c) Labor supply

(d) Financial considerations

(e) Civic or municipal aids or restrictions to manufacturing.

Provision for Proper Arrangement of Machinery

Making provision for the proper installation and arrangement of the necessary tools and machinery presupposes that the kind, quantity, and quality of the product have been decided upon and that due and proper care has been given to the selection of the machinery required in the manufacture of this product. Naturally the first consideration is the location of the lumber yard and dry kilns in relation to the incoming lumber to the factory. The location of the lumber yard will of course depend on the arrangement of railroad sidings. Several different plans for location of sidings may be possible for any given site and the most efficient layout can be determined only by close study of the factors entering into any given situation.

After deciding on the location of lumber yard and kilns this will ordinarily determine the point of entrance for the raw lumber into the proposed plant, and the next procedure will be to make a routing chart and thus establish the amount of floor space required for manufacturing purposes.

Having determined the entry point for the raw material, consideration should be given to each factory operation with the sequence required for manufacturing the product. The routing chart should list each separate part entering into the finished product, with the proposed volume of manufacture per unit of time, say, one year, and the sequence of operations required. Such a routing chart giving the sequence of operations will establish in a general way the sequence or arrangement of the various tools and machines throughout the plant.

After a tentative arrangement of the equipment has been completed a careful study should be made of how the product is to be transported from machine to machine, making proper provision for aisleways and location of trucks at machines to allow of efficient handling of material in and out of machines. The final arrangement will determine the amount of floor space required for machine rooms, and careful consideration should then be given to the location and size of store rooms, assembling, finishing, upholstering, crating, and shipping departments, factory offices, toilets, locker rooms, etc. With the approximate total amount of floor space decided upon, a tentative layout of the building may be made. The product of a furniture factory being comparatively light in weight, and consequently easily transported [illegible] ing will in most cases be found the most eco[illegible] points, although four or five stories in height [illegible] the limit. The various departments may [illegible] machine room and shipping department on [illegible] tional machine room if required on the second [illegible] finishing and upholstering departments on [illegible] being exercised to so arrange the various [illegible] flow of product may be as direct and unin[illegible] through each department and then on to the [illegible]

Upon completing the arrangement of the [illegible] the next problem will be one of transportatio[illegible] departments on the different floors, which is ac[illegible] by means of elevators. In connection wit[illegible] problem, thought should be given to the possi[illegible] conveyors, or small elevators from one dep[illegible] thus establishing more direct paths of flow th[illegible] by using the main elevators and also reduci[illegible] amount of handling required.

The floor space and general arrangement of the main manufacturing building having been determined, the next decision to be made is the type of construction to use. This is somewhat limited to materials available, although in most centers where a furniture factory is likely to be built the ordinary forms of construction such as reinforced concrete, slow-burning mill, or steel frame, will be found applicable. Reinforced concrete is rapidly coming into use as one of the most economical types of construction, when all factors are considered, and yet the writer regards the slow-burning, heavy-mill type of construction as particularly adaptable to a furniture factory.

Provision for Handling and Transporting Material

One of the most important problems confronting the furniture manufacturer is the receiving, handling, storing, drying, and transporting of the raw material, namely, lumber. Much thought and study should be placed on the arrangement of sidings, storage yards, dry kilns, cut-off saws, etc., as an efficient layout will pay for its development many times over in decreased labor and saving in time.

The lumber storage yard should be large enough to at least hold a year's supply in order that advantage may be taken of favorable market conditions. The storage yard should also be equipped throughout with industrial trackage laid parallel with the receiving siding. This trackage system should be served by at least two transfer tracks running at right angles to the receiving siding. With this arrangement lumber is unloaded and sorted directly on small lumber trucks or "bunks" of the ordinary kind and then by means of the transfer tracks the truck loads, containing about 4000 ft., are placed in storage ready to be taken to the kilns for drying.

The type of kiln used will depend on the thickness and kind of stock to be used. A dry-storage shed equipped with industrial trackage is also valuable as it allows for an accumulation of dry material and thus avoids delays in receiving lumber at the cut-off saws which might be occasioned by accidents to the kilns, stock spoiled in process of drying, or other delays between the kilns and the mill.

The same system of transfer tracks that serves the storage yard and kilns should be extended to the cut-off saws, where there should be provided hydraulic or screw lifts or elevators to raise the entire load of lumber and keep the top of the pile a few inches above the tops of the saw tables. It will be seen that with the above arrangement the lumber is not handled from the time it leaves the railroad car until it is placed on the table of the cut-off saw, and the consequent decrease in handling costs is at once apparent.

While the receiving and handling of the lumber should probably receive the greatest consideration in laying out the transportation facilities to and from the plant, yet railroad sidings to the power plant, for the delivery of machinery and coal, and to the shipping room for shipping the finished product, should not be overlooked but should receive thoughtful study.

Provision for Generation and Transmission of Power, Light, and Heat

On account of the large amount of refuse from most furniture

Note loading boom to left of mast and way in which entire machine to right is jacked up so empty log cars can pass under. The empty cars are run in and the first one is loaded, when the loader itself pulls out the next car, and so on until the load is completed. This is one of the many applications of the "sky line" method. Fig. 6—Crawler-type tractor, capable of doing work of 16 or 18-mule team, and also of working in soft ground. Fig. 7—Heavy-duty truck and two-wheel pole trailer used extensively in western motor-truck logging, showing characteristic load of about 3000 ft., log scale, and weighing from 4½ to 5 tons.

factories, which is available for fuel, it follows without much argument that in by far the majority of cases it will pay to erect an isolated power plant, unless capital is limited or the plant be very small.

The first decision to be made in starting the power-plant design is the method of transmitting power to the various machines in the factory. In by far the majority of cases the most efficient method of transmitting power from the prime mover to the principal machines in small and medium-sized plants is by means of shafting, pulleys, and belts. Electric individual or group driving of machinery is unquestionably the best and most economical where machinery is widely scattered, or where some of the machinery is operated only part time, but where most of the machinery may be arranged in one department and the majority of it is operated at all times, the initial expense and overall efficiency of driving from lineshafting take precedence over those of electric drive.

Upon deciding on the method of transmitting power to the various machines the next step will be to select the proper type and capacity of prime mover. The load factor in most furniture plants will average from 75 to 80 per cent of the connected load. An estimate must then be made of the power consumed by power-transmission equipment, consisting of shafting and belts or electric drives, and by adding the connected load, corrected for load factor, plus an allowance for mechanical efficiency of the prime mover, the indicated-horsepower capacity required to furnish the plant with power may be determined. The electric load and lineshaft load should of course be kept separate in order to determine the generating capacity required, also the electric lighting should be laid out and proper allowance be made both in the generator and prime mover.

The low-pressure steam requirements for dry kilns, heating, etc., should be determined and a curve drawn showing the average demand for low-pressure steam throughout the year. Assuming a steam consumption of 26 or 27 lb. of steam per indicated horsepower per hour for the ordinary Corliss type of engine and that 85 per cent of the exhaust will be available for heating and drying purposes, a curve should next be drawn showing the average available exhaust steam for the various months of the year, and upon comparing the two curves it will be seen at a glance during which periods of the year the heating and drying demands exceed the exhaust from the engine, or vice versa.

In most furniture plants the exhaust from the engine will exceed the requirement for low-pressure steam during the summer time and it therefore becomes a question as to how valuable this excess of exhaust steam is and how great an investment is warranted in cutting it down to the minimum. From a knowledge of the total steam requirements of the plant the amount of fuel required can be calculated, assuming that 20 to 25 per cent of the lumber cut finds its way to the boiler room as refuse or waste, and that the fuel value of the wood is about 20 per cent of that of the average bituminous coal, weight for weight. It is then a simple calculation to determine the cost of evaporating the excess of exhaust steam during such periods of the year as this excess exists. Any saving effected by reducing the amount of the excess exhaust steam, which would go to waste, should not only pay all fixed charges on any investment made to reduce this excess, but should also pay a return of at least 20 per cent per year on this additional investment. The type of engine best suited for driving a lineshaft load where efficiency, economy and continuous operation are permanent considerations is probably the slow- or medium-speed releasing-gear simple Corliss engine or the poppet-valve engine, which latter is similar in most respects to the Corliss except in the valve gear.

In choosing boilers for the plant the capacity required may be determined from the total steam demand, adding an allowance of 10 to 15 per cent for pumps and other incidental uses throughout the plant. By dividing the total maximum boiler capacity required into at least three units it will always be possible to operate the plant on two boilers, for even with a maximum demand for steam two boilers will carry the plant by operating at 150 per cent of rating.

The location and arrangement of the power plant are important as regards the economical transmission of power to the factory and the allowance for increase in capacity. Where lineshaft drive is used the power plant is located in a separate building, preferably near the center of the main lineshaft, though of course within easy driving distance from engine shaft to main recei ing shaft. This location of power plant is also fairly near the cen of distribution for steam and electric current.

The utilization of the factory waste or refuse so as to obtain the maximum fuel value is another problem which should receive its fair share of thought and study. Of course, shavings and sawdust from the various machines will be handled by an exhaust system to a separator on the boiler-house roof and then spouted to the boilers or shavings vault. In most plants the cuttings and culls are collected in push carts by a crew of men and wheeled to the boiler house where they are fed to the furnaces by hand. The above method of handling this part of the refuse is not only expensive from the standpoint of handling cost, but the full value of the refuse as fuel is not realized due to the manner of firing. The installation of a few small "hogs" or chippers, at convenient points in the plant where cuttings collect, discharging into the regular exhaust system will in many cases be found to be a paying investment. The power consumption is considerable and a certain amount of maintenance is required, but these disadvantages will frequently be found to be outweighed by the decreased labor cost and the increased efficiency obtained in burning the fuel.

Another improvement in the handling of refuse is in regard to feeding the excess shavings and sawdust which ordinarily are allowed to collect during the day in a so-called shavings vault. In most plants the contents of the shavings vault must be fed to the furnaces with a shovel, which is not only laborious but prevents the full fuel value being realized. In the design of a power plant for a woodworking factory for which the writer was partly responsible, overhead bins were installed instead of the customary shavings vault. These bins fed by gravity to a short length of screw conveyor discharging into the furnace fronts, a separate conveyor being provided for each boiler. The speed of the conveyors could be varied by means of a friction drive, thus allowing the quantity of shavings and sawdust fed to the furnace to be regulated in accordance with the load on the boiler.

Fire Protection

In a woodworking establishment the fire hazard is naturally much greater than in a metal-working plant, consequently more than ordinary care should be exercised in decreasing the fire hazard to a minimum and preventing the spread of fire in case it does start. Buildings should probably not exceed 250 to 300 ft. in length without dividing them by suitable fire walls at least 17 in. thick, and extending well above the roof line. Finishing and upholstering departments should if possible be isolated from the rest of the plant by fire walls, and if they are on upper floors and any great distance from stairways, outside fire escapes should be provided.

All stair wells and elevator shafts should be enclosed in fireproof towers, and to make fire walls and fireproof towers effective all openings should be fitted with automatic fire doors. It is also well to note that all stairs should be of non-combustible material so they cannot be destroyed in case fire is communicated to the stair well itself. All sash should be steel and the windows opposite adjacent buildings, where buildings are 30 ft. apart or less, should be glazed with wire glass. It almost goes without saying that a good sprinkler system should be installed throughout the entire plant with plenty of yard hydrants and a good supply of fire hose. All motor-control switches should be enclosed in steel boxes so arranged that the box cannot be opened when the switch is closed. All switches for motors driving spray-booth fans, or for motors in other locations where inflammable gas or dust is prevalent, should be of the remote-control type enclosed in tight steel or iron cases, with a push button near the booth or other machine. Spray-booth fires are a constant source of danger and the method above mentioned of controlling the fan motors is well worth the investment required.

Proper Accommodation for Workers

Under accommodations for workers may be included the lighting, heating, toilet, and locker-room arrangements of the plant. The day of the dark, poorly heated and ventilated factory building with inadequate and unsanitary toilet facilities is past, for the simple reason, if for no other, that any self-respecting man will

Fig. 14 A City of Lumber and Shingle Mills. Lumber Brought in in Form of Great Log Rafts

not work under such conditions. Bright, cheerful surroundings, comfortably heated and well ventilated, are no longer regarded as an expense by the modern executive but as an investment which pays large returns in increasing production and quality of product, decreasing labor turnover and promoting contentment and loyalty among the employees.

The far-too-usual method of providing a drop cord with a bare lamp over each machine or at each workman's bench with a few thrown in for general illumination should not be tolerated in this day and age when good, efficient fixtures may be had at such reasonable cost. Where walls and ceilings are painted white with some good industrial enamel, efficient lighting may be obtained through a proper selection of reflectors or fixtures at a comparatively small cost in power consumption.

With regard to heating, probably the most ideal system is the hot-blast, for such a system provides adequate ventilation as well as heat and in the summer time may be used to cool the air introduced into the factory by circulating cold water through the heating coils.

The toilet and locker rooms should be centrally located with regard to the building or floors which each serves, and preferably placed in a service wing, as already mentioned. By so locating these features valuable manufacturing space is not taken up and good light and ventilation may be obtained. Washing facilities should preferably consist of enameled roll-rim cast-iron sinks with no stoppers in the waste. Such equipment has the advantage that it is easier to keep clean than individual wash basins and forces the men to wash in running water, an important point in preventing the spread of disease. Every man in the plant should be provided with a pressed-steel locker where he may change his clothes, and the addition of a few showers and a comfortable, well-lighted room where the men can eat their lunches will be found to be not only conveniences provided by a generous management, but features which add still more to the contentment and loyalty of the men.

As mentioned before, these few notes are not intended as a treatise on the design of a furniture factory, but merely as a brief discussion of some points which the writer feels are worthy of serious consideration. The many factors affecting the design and construction of a plant are so important in their bearing on the final overall efficiency of the plant, that the problem is quite properly one for none but an experienced engineer.

THE USE OF WOOD IN FREIGHT-CAR CONSTRUCTION

By H. S. Sackett,[1] Chicago, Ill.

The fact that over two billion feet of lumber and timber are used annually in the United States for the maintenance of freight equipment and for the construction of new cars, representing an annual outlay for material alone of over $50,000,000, is ample evidence of the importance of wood in this big industry.

In the construction of the first cars wood was almost universally used for all parts, except of course the running gear. Within the

[1] Asst. Purchasing Agent, Chicago, Milwaukee and St. Paul Railway Company.

Photo by *Lumber*, weekly, St. Louis, Mo.

Fig. 16 Typical Large Sawmill Plant Including Dry Kilns, Planing Mill and Covered Storage

past decade, however, with the introduction of heavy motive power—which spells long and heavy trains—it has been found that wood is no longer capable of withstanding the heavy shocks incident to such operations, and it is generally conceded by all car builders that the freight car of the future must have a steel underframe and steel draft rigging.

This limits the use of wood to unimportant parts of the underframe, such as intermediate sills and cross-beams, and to the superstructure of the car. In the case of open-top cars this means only posts and side and end plank and decking, but in box, stock, and furniture cars, etc., it means also siding, lining and roofing.

Steel vs. Wood for Open-Top Cars

To take up the question of open-top cars first, statistics gathered by operating officials of some of the large railway systems seem to indicate that the cost of maintaining steel gondola cars over a period of years is greater than for composite (wooden and steel) cars of the same type. The data[1] collected show that all-steel gondola cars in their twelfth year of service cost over 36 per cent more to maintain than did the composite gondola. Of course, it is probable that during the first five years of its life the steel gondola cost less to maintain, but it is felt that taking the entire twelve years as an average, the cost would be more for the maintenance of the steel than the composite gondola.

It is furthermore interesting to note that but 60 per cent of the composite gondolas in service required repairs, while 72 per cent of the steel gondolas were obliged to be brought to the shops. The actual time that a car is in service and earning money for the road is an important consideration in determining its general utility.

A table in the complete paper shows that the annual cost of repairing freight cars has increased from $59.30 in 1908 to $80.30 in 1914, an advance of over 35 per cent. This higher cost is due, of course, to a number of factors, but it is felt that no small part of it is due to the use of steel, which requires a greater outlay for material and a higher cost to repair, owing to the fact that it takes longer to make like repairs on a steel car than on a wooden one. It must also be borne in mind that this higher cost is very largely due to the much rougher usage to which freight equipment is now subjected. In recent years the freight business of the railroads has grown enormously, and has necessitated the construction of gravity yards for switching, and the use of fewer switchmen per cars handled than in former years. This has resulted in severe handling of freight equipment, and is probably responsible to a greater degree than any other factor for the increased cost of repairs in recent years.

Steel vs. Wood for Closed-Top Cars

In the case of closed-top cars, such as, for example, stock, box, and furniture cars, there is but little doubt that under present railroading conditions the understructure should be of steel with a wooden superstructure. The steel understructure is required to withstand the shocks of service and to give rigidity and stability to the car, while the wood is desired to give lightness and general utility to the body. Some all-steel box cars are in use today, but

their heaviness and the fact that nails and cleats cannot be used in them to brace and hold the lading, are strong factors against the use of this material. It has not met with favor with shippers generally and probably will not as long as wood continues to remain available.

Graded Lumber in Car Construction

It seems pertinent to say a word at this time as to the grades of material required for the different parts of the body of the car. In the early days when the supply of wood in this country was thought to be inexhaustible, clear grades of wood were generally demanded by the car builders, and in the construction of new cars this is generally the practice at the present time, especially for car roofing and siding, sound-knotted stock being used for decking and lining. Some of the more progressive railroads, however, have gone a step further in recent years and many are now using sound-knotted stock for siding and roofing for repair and maintenance work. There is no doubt but what such a practice is economical and based on sound judgment, for certainly there is no necessity for using clear material for the repair of many classes of freight equipment, the life of which may not be in excess of seven to ten years. One large railway system which not only constructs its own cars but does repairing on a large scale, has adopted this practice and the saving amounts to over $500,000 per year.

An important feature of car construction which is decidedly in wood's favor, is its general ease of working and adaptability to repair, and this is brought about not only from its qualities which make it easy to cut, saw and shape, but also by its almost universal availability.

It is also rather curious that the salvage value of wooden cars is greater than that of steel cars, and no one doubts this who has seen the two types of cars in a seriously wrecked condition. The wooden car may be quickly and easily repaired, while the steel car is only rehabilitated at a high cost, or for the most part is fit for the junk pile.

The Importance of Well-Seasoned Wood

Before using wood in the building of freight cars it is vitally important that it be well seasoned. When our grandfathers built a house they expected it to last a century, and it usually did, for they took great care to properly season the wood before putting it to use. In the houses nowadays, however, we use wood almost before it is dry from the saw, and the result is that our American frame houses today are old at fifteen or twenty years. Too often today we also see freight cars built of green lumber and timber, with the result that within a few months the bolts are loose, the wood having shrunk away from the original fastenings. This causes rapid deterioration and large timbers often quickly rot, particularly those containing sapwood.

Increasing attention has been given in recent years to the preservative treatment of certain parts of freight cars, and experiments have been made by some of the more important railway systems in the treatment of such items as stock-car decking, side and intermediate sills, roofing, etc. While these experiments have not been conducted for a sufficient length of time to determine actual results, the indications are that the preservative treatment of such car parts as are particularly liable to decay is profitable and will shortly be adopted as standard practice by the more progressive railroads. The conclusion is inevitable that the superstructure of freight cars will continue to be of wood as long as it is available at a reasonable price.

CREOSOTED WOOD-BLOCK FACTORY FLOORS

By LAMBERT T. ERICSON,[1] TOLEDO, OHIO

The use of creosoted wood blocks for factory floors has been so extensive during the past few years that it is hardly necessary to go into details in regard to the advantages of this type of flooring. Most engineers and architects have come in contact with this material at first hand, so that this paper will be confined to a discussion of (1) the material used; (2) the problems encountered; and (3) the field covered.

Southern yellow pine has been employed almost entirely for this work, except on the West Coast, where Douglas fir and tamarack are used. Long-leaf pine is usually specified, but short-leaf pine is also adaptable for the work. The lumber should be thoroughly air-seasoned before being cut into blocks, and then should be given a preservative treatment with coal-tar creosote oil to preserve the wood from decay. Hard woods, such as gum, beech, and maple, can be used, but they are not favored on account of the difficulty in properly seasoning the lumber and the tendency of the blocks to warp and check after they are cut. The coniferous woods are more homogeneous in grain and texture and are consequently more adaptable. Soft wood compacts under service and consequently it is just as serviceable as hard wood, and has the advantage of not becoming slippery under traffic.

It should be understood in the beginning that factory flooring with creosoted wood blocks cannot be grouped under one general heading and specification. The conditions under which the floor is to be used must first be studied and the specifications made to suit. Creosoted wood blocks can be laid to meet practically all factory conditions if the conditions are first properly analyzed. The real reason for most of the trouble encountered with this type of flooring is the fact that wood expands and contracts with various conditions of the atmosphere and the moisture content of the blocks. It is therefore necessary to lay the individual blocks in such a way as to allow for this change in volume, which in extreme cases may be as much as 5 per cent. The individual units in the floor must be bound tightly in place with a binder which will allow this expansion and contraction and which will exclude water from the underside of the floor. As long as the blocks are held tightly and firmly in place and a smooth surface is maintained the floor will wear almost indefinitely, but as soon as they become loose and the surface rough they will break up into sticks very quickly.

Conditions to be Met in a Successful Installation

The three most essential requisites for success are: (1) thoroughly air-seasoned lumber; (2) a smooth, solid foundation base; and (3) a waterproof and elastic binder to hold the units in place. In the majority of cases factory floors are dry most of the time; consequently, the lumber should be thoroughly seasoned, in order to keep the shrinkage to the minimum. Blocks cut from green or semi-dry lumber will shrink in volume to such an extent that they will often have to be taken up and relaid. If it is possible to do so, it is advisable to use a concrete base for the installation of these floors. The base should be strong enough to carry the entire load and should be finished smooth and level so that it will not be necessary to use a cushion between the concrete and the blocks in order to secure a level floor and uniform bearing for the individual units.

Wherever a cushion is necessary between the concrete and the blocks, it is advisable either to use a mixture of portland cement and sand or a bituminous mastic. The latter is preferable in a great many cases on account of being both waterproof and elastic. It is standard practice today to lay the blocks directly upon a smoothly finished concrete without any cushion whatever. It is also customary to give the base a thin, even coating of coal-tar pitch before installing the blocks, so that the underside of the blocks may be thoroughly sealed and made waterproof.

The elimination of cushions and the use of a successful waterproof binder in the joints of the blocks, thereby eliminating the possibility of shifting of the base and a loosening of the units, has permitted a reduction in the depth of the blocks used. Factory floors are now being very successfully installed throughout entire manufacturing plants with blocks as shallow as 2 in. in depth.

Successful installations may be made on timber and plank foundations in mill-type buildings, but care must be taken to see that the timber in the foundation is sound and that the blocks are afforded a firm and even footing. A bituminous-mastic cushion between the planks and the blocks is now being extensively used and is proving very successful.

The Uses of Wood-Block Flooring

Creosoted wood-block floors are being installed in machine shops, forge shops, foundry molding and core rooms, casting cleaning and

Fig. 27—Softwood piles, the lumber being stored for natural drying; served by industrial railroad with storage-battery locomotive.

state. They also vary from low to high temperatures, and in some cases the blocks are submitted to the action of molten metal. The extreme variation in the demands covered by the above list of industries gives a fair idea why it is necessary to study the individual job at hand and draw a specification to meet the particular work.

For ordinary factory purposes the proper treatment for the blocks is 6 lb. of creosote oil per cubic foot of timber. This is injected by the Rueping process and is sufficient to preserve them from decay. When they are to be subjected to considerable moisture or to the weather, they should be treated with 12 lb. of oil per cubic foot of timber by a combination of the empty- and full-cell processes. This extra amount of oil insures better waterproofing of the blocks.

Floors which are to be subjected to considerable moisture, or to weather conditions, should be laid with ample provision for expansion. It is good practice to provide ample space between the individual units to take care of this expansion. These joints should be flushed full of a waterproof, elastic binder, which should preferably be coal-tar pitch of a consistency which will not soften up under atmospheric or room temperatures. Coal-tar pitch has proven the most successful binder and filler for creosoted wood blocks, as it is a derivative of the same base as creosote oil, and thus readily unites with the oil in the blocks.

ELECTRICALLY DRIVEN SAW MILLS

By ALLAN E. HALL,[1] MILWAUKEE, WIS.

THE complete modern plant for the manufacture of lumber includes everything required to transform the growing tree into finished lumber ready for the builder; and this plant naturally divides into forest equipment and mill equipment. The forest equipment, which includes logging machinery and railroad and water transportation of the logs to the mill, is not considered in the present paper.

The capacity of a sawmill is regularly given in thousands of feet board measure per day of 10 hours. The power required for sawmill alone varies from $4^1/_2$ to 8 hp. per 1000 ft. of lumber per day; e.g., a sawmill of 100,000 ft. daily capacity will require from 450 to 800 hp. The lower figure is for mills cutting small and medium pine logs; the higher figure for Pacific Coast mills working the heaviest timber, or mills sawing hardwood. The planing mill will require from 2 to $3^1/_2$ hp. per 1000 ft. on the same basis. The total power for milling is therefore from $6^1/_2$ to $11^1/_2$ hp. per 1000 ft. board measure of lumber sawed per 10 hours.

Two things should be kept in mind in estimating and comparing power used in different sawmills: First, two sawmills rated at 100,000 ft. board measure per day each may deliver this 100,000 ft. in very different forms. The first may be a "board mill" and the entire day's cut may be 1-in. boards. The second may be a "timber mill" making 50 to 60 per cent of the logs it handles into timbers or large dimension pieces. It is obvious that one 12-in. by 12-in. by 16-ft. timber will add just as many board feet to the day's tally as 12 boards 1 in. by 12 in. by 16 ft., but the latter will have consumed much more power. Second, it consumes more power to saw hard, dense wood than to saw soft, light wood. Some mills work hardwood or softwood exclusively; others must cut various kinds just as they come, owing to the timber supply being of mixed varieties.

Conditions of the Problem

In deciding whether to drive a sawmill by lineshaft or motors, the first consideration is the probable life of the plant. Unlike most manufacturing plants, the sawmill must nearly always be built close to the supply of raw material; for it is not commercially possible to transport sawlogs far from where they grow, except in the case of valuable timber like mahogany and other tropical hardwoods. When the supply of accessible timber is sawed, the plant must be abandoned or moved with a very small salvage value.

[1] Allis-Chalmers Manufacturing Company.

wiped out from the profits in a few years—fifteen, ten, or even eight years—without making too great an annual charge.

The size of the sawmill plant is important. It is found that for very small mills the first cost of the electric power plant and motors is greater than for a steam plant and belted drive. For medium-size sawmills the first cost does not differ greatly when everything is considered; and for large plants the first cost may be less for a motor-driven than for a shaft-driven mill.

Accessory or by-product equipment will affect the choice between the two kinds of power transmission. As previously ex-

Fig. 1 Filing Room, with Motor Direct-Connected to Automatic Band Sharpener

plained, the planing mill is considered as a part of the complete installation; but beyond this every intelligent lumberman is constantly trying to make the waste wood from his sawmill into useful products. As an example, a large mill recently built for the manufacture of yellow-pine lumber makes from waste wood (*a*) kiln sticks for spacing lumber in the dry-kiln stacks, (*b*) lath, (*c*) rosin-barrel staves, (*d*) shingles, (*e*) box boards and cleats, (*f*) short stove wood, (*g*) molding strips and (*h*) ground chips for fuel. More-

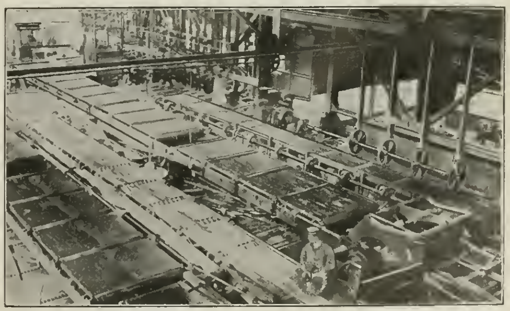

Fig. 2 Interior of Sawmill Showing Motor-Driven Slab Slasher and Trimmer

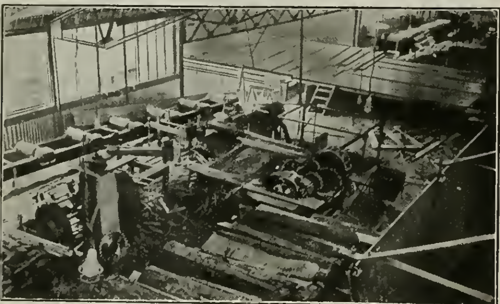
over sawmills are built today for producing small wood specialties primarily from the log, the output of lumber in the form of boards or other building material being small and incidental. One large plant for instance has recently been built for making oval wood dishes, butter boats and clothes pins. A small sawmill followed by such a remanufacturing plant is usually motor-driven, while the sawmill alone might not justify the investment; for the small specialty machines can be driven electrically with convenience and economy.

A unique condition of sawmill operation is that fuel costs nothing. The waste wood from the mill contains 8500 to 9150 B.t.u. per lb. when dry, the larger values coming from highly resinous wood, although as it falls from the saw it contains from 40 per cent to 50 per cent of moisture, or even more. Generally the mill

roduces more waste wood than can be used for fuel or otherwise, nd this surplus must be sent out in a long conveyor trough and urned in a pit or in a closed iron "burner." Decreased fuel conimption by saving power-transmission losses is therefore of no iterest to the lumberman. The argument has even been made that ecreased fuel consumption under the boilers is poor economy, ecause the saved wood must be conveyed a longer distance to the burner" than to the boiler room, thus using more engine power.

In sawmills, as in other industries, motors give the advantage f unit driving, and the whole mill is not dependent on one line iaft or main belt. But it is to be noted that in the sawmill proper iis advantage is not so great as in most other manufacturing lants. In a machine shop or other factory where one machine r small group of machines is making a finished product independntly of all others, a stoppage of one machine or group will not ffect the others. In a single band mill every piece of lumber from ie log passes through all the machines serially, and a stoppage of ne machine in the chain will soon shut down the mill. In a sawiill with two log-cutting saws there will be two streams of lumber, nd failure of one machine will generally only affect one side. After ie lumber passes the trimmer and reaches remanufacturing and y-product machines, the full advantage of unit driving is gained, or here one machine does not depend on another. With the fore-



ig. 3 Lath Mill Showing Direct-Connected Motor Driving Lath Bolter and Lath Machine

oing conditions in mind, a comparison may be made, first as to lant details and cost, and second as to operating expense.

Comparison of Plant Details and Cost

Sawmill boilers are either ordinary horizontal tubular or of waterabe types. When burning sawdust a large furnace is required, hich is generally of Dutch-oven design. A fuel-storage house is uilt close to the boilers, with the fuel conveyors arranged either to ischarge sawdust from the mill direct to the furnaces or to carry on to the storage house and return it when needed. When the elted mill and non-condensing Corliss engine are replaced by the ondensing steam turbine and motor-driven mill the steam conumption of the prime movers will be cut about one-half, which llows a reduction of boiler capacity to be considered in comparing he cost of the entire plant. The boiler capacity needed for various uxiliary steam cylinders used in the mill will of course remain the ame as before.

The belted sawmill, except in plants too small to be of practical iterest, is generally driven by a simple non-condensing Corliss ngine. It has not been found worth while to install compound r condensing engines when fuel was valueless, simply for the reuction in boiler plant. When motor driving of a proposed plant s in contemplation, the prime mover may be a simple or compound, ondensing or non-condensing steam engine direct-connected to he generator, or else a steam turbo-generator. Fuel cost of course iakes the gas or oil engine out of the question and plant cost liminates hydroelectric power except in rare cases.

It has been said in an earlier paragraph that the standard sawiill plant includes a planing mill. This should be placed 200 ft. r more from the nearest roofed point of the sawmill proper (to ieet insurance rules), which means 300 to 600 ft. from the main power house. Motor driving of new planing mills, except when very small, has become almost universal, so that this is generally assumed at the start. If we belt-drive the sawmill we must then have one prime mover for it and a steam-electric plant for the planing mill. It is obvious that there should be only one boiler plant and one engine room, containing both prime movers. But if the sawmill as well as planing mill is electrically driven, the two prime movers may be combined into one large enough to drive both mills, which is economical in first cost and is often done.

For the same reasons which have brought it into favor in other industries, the condensing steam turbo-generator has become almost universal in motor-driven sawmills; and compound condensing engines are not now running in any mill with which the writer is acquainted. When deciding on the method of power transmission, the choice for large mills is commonly made between (*a*) a sawmill belted from a simple Corliss engine and a planing mill motor-driven by a steam turbo-generator; and (*b*) both mills motor-driven by a turbo-generator. The comparison of costs which follows is on this basis for the larger mill, though for the smaller one both mills are belted from engines.

In a shaft-driven mill the weight and cost of the lineshaft and various countershafts are considerable. The power-receiving section of the lineshaft is about four inches in diameter in a single

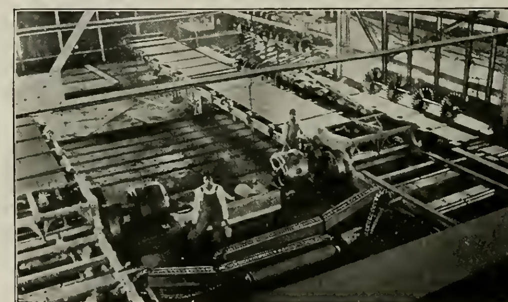


Fig. 4 Interior of Sawmill Showing Two Direct-Connected Motor-Driven Edgers

band mill, and 8 in. to 10 in. in diameter in the largest mills, and the shaft may be 300 ft. long. In large mills countershafts will be required for the log jack, log cut-off saw, log canter, band mill, gang mill, resaws, edgers (this requires a right-angle drive, usually through mortise gears), slasher, trimmer, hog, lumber sorter, timber trim saw, and lath mill. When the individual motor drive is installed all these shafts with their attachments are not required, and the difference in the total of sawmill machinery is almost entirely in these omissions. All the cutting machines, conveyors, and transfer and roll drives will be little changed. The amount of this saving is given below in three cases, the figures covering all sawmill machinery proper, installed, but no power-house equipment.

	Mechanical Drive		Electrical Drive	
	Weight, Lb.	Price	Weight, Lb.	Price
Mill No. 1.......	445,296	$112,345	402,749	$104,410
Mill No. 2.......	701,500	173,5 0	620,000	153,698
Mill No. 3.......	763,150	189,079	674,150	166,789

Sawmill and woodworking machines are almost always driven at constant speed, in one direction, and (except band mills, band resaws, and a few other cases) can be started at light load; so the squirrel-cage induction motor is generally applicable. The direct-current open motor is of course objectionable on account of fire risk from sparking commutators. For driving band mills, heavy band resaws, and in other places where large starting torque is necessary, the wound-rotor motor with starting resistance is used. The current (60-cycle, 3-phase) is commonly generated and used at either 480 or 600 volts, avoiding the use of transformers except for lighting. As all the motors will be probably set within 600 to 800 ft. of the power plant, the saving in wiring does not justify high generator voltage and transformers.

drive. In Table 1, which gives the estimated cost of a single band mill with a daily capacity of 30,000 ft., the figures are about 11 per cent higher for motor drive, but in Table 2, which is for a double band and resaw mill with a daily capacity of 120,000 ft., the first cost is about 8 per cent less for the motor drive.

Comparison of Operating Conditions and Expense

In operating expense the motor-driven sawmill makes a saving in power-transmission loss, upkeep of shafting and belting, use of oil, waste, and supplies, depreciation, fire risk and insurance premium. The complete paper gives a table showing the power consumption of various sawmills for both mechanical drive and electrical drive, the horsepower consumed being less in the case of electric drive.

The average life of belts in a sawmill is not more than four years, which means a running expense of 25 per cent of the total belting cost yearly. The saving in oil, waste, etc., by changing over from shaft drive to motor drive has been estimated at 40 cents per 1000 ft. of lumber per day. No attempt is made to give comparative figures for depreciation, but the lumber manufacturer's accountant should consider the low second-hand value of shafting equipment if it must be moved and refitted for new conditions, as contrasted with the easy interchangeability of motors. One of the lumbermen's mutual insurance associations recognizes motor driving by a reduction of 25 cents in premium. Another association, while not specifically recognizing electric driving, usually makes a 5 per cent deduction from total premium on account of the clear and open condition of the lower floor thus produced.

Separate steam engines are also sometimes used in a belt-driven plant to drive certain large machines (e.g., a gang mill) or groups of machines. These engines proportioned for their average load do not have the peak-carrying capacity of equivalent motors with a large generator behind them. When the mill is driven by several steam engines of small size a reduction of shafting equipment may be made, but each engine must carry its peak load without help. Motors of corresponding horsepower rating connected to one large generator will draw on an ample power reserve during peak loads. Two gang mills have come under the writer's observation, of the same size and make, one driven by a steam engine belted to it individually, the other motor-driven, both machines nominally running at 225 r.p.m. The engine-driven gang ran at 225 r.p.m. light, and 200 r.p.m. fully loaded. The motor-driven gang ran at 225 r.p.m. light, and about 223 r.p.m. loaded. As the rate of lumber feed to the gang is governed by the speed, the steam-driven gang was cutting about 10 per cent less than the other. Cases are on record where mills by simply changing from shaft drive to electric drive have increased their production 15 per cent. This problem of speed maintenance has not been sufficiently studied by sawmill operators.

Details of Motor Application

The equipment for hauling logs into the sawmill and cross-cutting them may be motor-driven. The remaining log-handling equipment is actuated by direct-connected steam cylinders. Sometimes an overhead log "canter" is used for turning logs, supplementary to the "nigger." It turns the logs by a hook attached to a chain wound on a drum and may be motor-driven.

On the other hand jump saws for cross-cutting boards and timbers, hinged transfer skids, the mechanism for raising press rolls on edgers and gangs, and for raising saws on a trimmer, are moved by direct steam or compressed-air cylinders. Also the carriage which holds the log while being sawed is almost always reciprocated by a steam engine through a wire rope or by a steam cylinder directly connected to the carriage itself. All these steam-actuated devices are so simple and positive in action that there is no apparent advantage in developing electrical methods as a substitute.

The other principal machines are connected to the motors through flexible couplings, except band mills, band resaws, and gangs. The band mills may be so driven, but there are certain objections which should be considered: the motor cuts partly through the mill floor, is inconvenient for inspection, and in the way of workmen; and motor speeds do not always match the speeds of the band 8, 9, 10, and 11 ft. in diameter. Irrespective of wheel diameter, the saws, and hence the wheel rims, are run at speeds up to 10,500 ft. per min.—plain cast-iron wheels at twice the ordinary limiting speed of engine flywheel pulleys. Another condition sometimes weighing against connecting a constant-speed motor directly to a band-wheel arbor, is that in northern hardwood mills the saws may be run at different speeds in winter and in summer. If much frozen timber reaches the saw, operators prefer to reduce the speed 1000 or even 2000 ft. per min. below that used when logs are clear of ice.

Gang mills run at such a low speed and require so much power that direct-connected motors of sufficient size would be very expensive, and standard practice up to the present has been to belt from a higher-speed motor.

The lumber-transporting equipment, including live rolls, chain transfers, chain and belt conveyors, is most conveniently and cheaply group-driven, though there is now a tendency to go farther in the use of individual small motors than there was a few years ago.

The filing-room machines for sharpening saws require little power and are arranged for mounting individual motors directly on the frame in most cases.

When specifying sizes for sawmill motors it must be remembered that very great and sudden peak loads are encountered, and the ratings must be larger on this account. In general, it is found that the load factor on an entire sawmill is about 60 per cent of the total nameplate rating of the motors.

A condensed list of the machines found in the ordinary sawmill follows, the sizes of motors suitable therefore being stated in each case.

Machines	Motor sizes
Log jack, for hauling logs into the sawmill	25 to 50 hp.
Circular log cut-off saw, for dividing long logs after being drawn into the mill	25 to 50 hp.
Drag saw, for cutting off logs too large for the circular saw above mentioned	15 to 40 hp.
Overhead log canter, for turning large logs lying on the log storage deck or on the carriage	10 to 20 hp.
Band mill, for ripping the logs which are moved back and forth in front of it on the carriage	100 to 300 hp.
Circular head saw, sometimes used instead of band mill	100 to 400 hp.
Power setting machine, for moving log forward after every cut into position for the next cut. This machine is mounted on the carriage. Two types are used, one direct steam-driven, the other power-driven. The latter is used exclusively for the heaviest work, and motor may be mounted on carriage	5 to 10 hp.
Live rolls, or power-driven rolls, for transporting lumber after being sawed. These are connected and driven together in trains of 6 to 20 or more, according to the mill design; power required per roll	0.4 to 0.6 hp.
Band resaw, for further reduction of large pieces dropped by the head band mill. It may be either vertical or horizontal The latter is used for resawing slabs as well as splitting thick stock from the head band	75 to 200 hp.
Transfer chain tables, for moving lumber sidewise between machines. These are of such varying length and width according to the individual case, that no power requirement can be specified.	
Gang mill, for sawing entire log into boards at one passage through the machine. Two opposite slabs are taken off the log by the head band saw, giving the log two flat faces, after which it is fed to the gang	50 to 400 hp.
Edger, for ripping bark edges from the boards and squaring them	15 to 250 hp.
Slab slasher, for dividing waste stock into short lengths for lath, stovewood, or other by-products	20 to 75 hp.
Trimmer, for cutting ends off boards and making them of standard length	20 to 75 hp.
Swing cut-off saw, for hand-trimming of large timbers, etc.	10 to 25 hp.
Timber sizer, for surfacing two or four sides of timbers at one operation	50 to 60 hp.
Lath bolter, for preparing lath bolts from slabs or other waste wood	30 to 60 hp.
Lath machine, for making lath from bolts	20 to 30 hp.
Hog, a grinder with knives on a revolving disk, for chipping waste wood for fuel or other purposes	25 to 150 hp.
Planers, of great variety in size and type. The largest standard size requires about 75 hp.	
Exhaust fans, for transporting dust and shavings from planers to fuel-storage house	25 to 150 hp.
Chain conveyors, for transporting waste wood and sawdust, the length varying with the mill design up to about 350 ft.	5 to 30 hp.

PROCESSES AND EQUIPMENT USED IN WOOD PRESERVATION

By E. S. Park,[1] Pittsburgh, Pa., and J. M. Weber,[1] Orrville, Ohio

Processes for the use of a preservative agent in the treatment of timber to prevent its decay or its destruction through the boring of insects may be classified into three groups: (1) Surface application: coating the timber with preservative by means of brush or spray; (2) open-tank treatment: immersion of the timber in preservative in open tanks; and (3) pressure treatments: immersion of the timber in closed tanks or cylinders with the application of pressure above atmospheric to force the preservative into the wood. It is only in the treatment of timber under pressure in a closed cylinder that the methods employed are interesting from an engineering standpoint, and this paper is accordingly devoted solely to such plants.

The pressure process has as its prime object, first, the distribution of the preservative throughout the wood as uniformly as possible; and second, the securing of an absorption of a sufficient quantity of the preservative to insure the results desired. The essential feature of all pressure methods is the use of pressure to force the preservative into the wood. This is accomplished in several ways, the kind of wood, the use for which it is intended or the kind of preservative used, making it necessary or advantageous to vary the methods employed. The timber is treated in closed retorts or treating cylinders built to withstand a pressure of 250 lb. per sq. in. and equipped with steam coils for heating the preservative.

The most widely used preservatives and those generally recognized as the most efficient are coal-tar creosote and zinc chloride, the latter being applied in the form of a 2 to 4 per cent aqueous solution. In one process employed in the treatment of cross-ties a mixture of 80 per cent zinc chloride solution and 20 per cent creosote is used. In treating with creosote the amount injected ranges from 4 to 20 lb. per cu. ft., depending on the kind of timber, the process employed, and the proposed use of the treated timber. When zinc chloride is used the aim is to treat the wood to refusal, the strength of the solution being regulated to give an absorption of approximately 1/2 lb. of dry salt per cu. ft. of the wood treated.

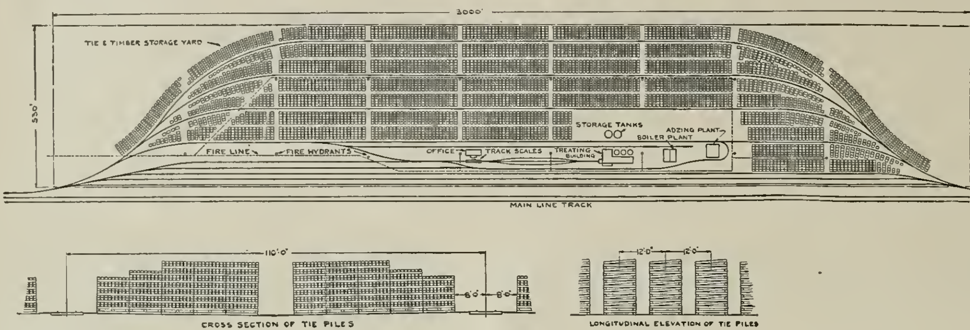

Fig. 1 Plan Showing Layout of Entire Plant

Pressure Treatments

Pressure treatments may be grouped into two classes as follows: (1) Full-cell process, the object of which is to fill the intercellular spaces of the wood as completely as possible with preservative; and (2) empty-cell process, the object of which is to secure as thorough and deep a penetration as possible with the use of a minimum quantity of preservative.

In the full-cell process the timber is placed in the retort, a vacuum is drawn, and, without breaking the vacuum, the retort is completely filled with the preservative fluid. The vacuum not only accelerates the entrance of the preservative into the retort but also makes it possible to force the preservative into the timber more quickly and with less pressure than is the case when the preservative must displace or compress the air in the wood. After the

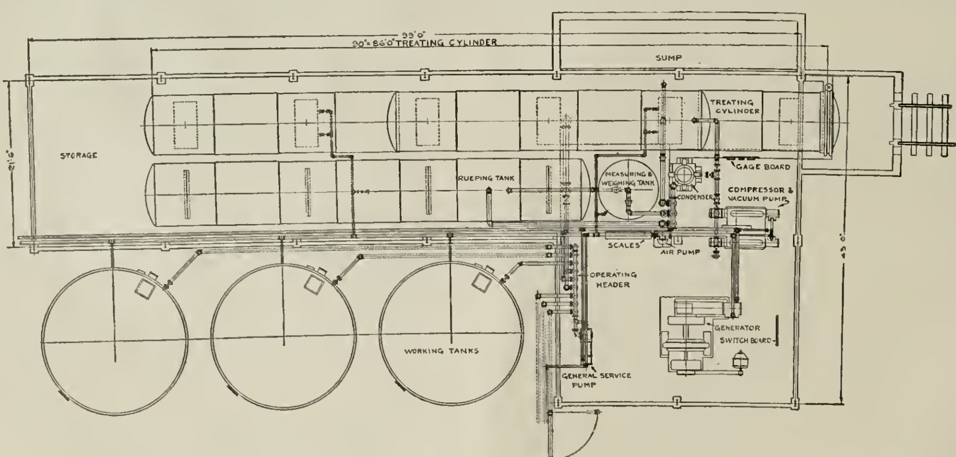

Fig. 2 Equipment Used in Treating Process

[1] Pittsburgh Wood Preserving Company.

and maintained at 125 to 180 lb. per sq. in. until the required amount of preservative has been forced into the wood. The pressure is then released, the preservative drawn from the cylinder, and as a rule, another vacuum is drawn, the object of this final vacuum being to remove the surplus preservative from the surface of the timbers and hasten the dripping of the preservative so that the timber can be removed from the cylinder as soon as possible.

In the empty-cell process no preliminary vacuum is employed and to enter the wood the preservative must therefore displace and, to some extent, compress the air in the wood. Such is the treatment known as the Lowry process. In the more widely used Rueping process the entrance of the preservative into the wood is further retarded by subjecting the timber to an initial air pressure of from 50 to 75 lb. per sq. in., after which the preservative is forced into the cylinder at a higher pressure. After the treating cylinder is filled the procedure in empty-cell processes is practically the same as in full-cell treatments except that the final vacuum is held longer. The results obtained, however, are quite different, as in the empty-cell treatments the release of the pressure and the removal of the preservative from the retort permits the expansion of the air compressed in the wood. The effect of the final vacuum is to cause further expansion and, to some extent, expulsion of the air in the wood and a corresponding expulsion of a portion of the preservative that was forced in during the pressure treatment. The result is a thorough penetration with a minimum amount of preservative. Empty-cell methods are used almost entirely with creosote and in treating timbers which do not require the complete filling of the interstices of the wood. The cost of such a treatment is considerably less than by full-cell processes, as from 25 to 40 per cent less preservative is required.

In some cases, particularly where the preservative used is a solution of zinc chloride, or a mixture of zinc chloride and creosote, and in the treatment of green or partially seasoned timbers with creosote, the timber is first subjected to treatment with live steam in the closed retort, followed by a drawing of the vacuum to remove the steam and vapors. This, to some extent, vaporizes the sap and moisture in the wood and facilitates the entrance of the preservative.

Typical Treating Plant

It will be seen that the essential equipment of a timber-treating plant includes a treating cylinder or retort and facilities for carrying on therein; the application of live steam to the timber, the compression of the air, the application of pressure to the preservative fluid and the drawing of a vacuum, or, more strictly, a partial vacuum. A typical treating plant is shown in Fig. 1. It is a single-cylinder plant with a treating capacity of from 400,000 to 700,000 cross-ties per year, depending on the kind of wood treated and the particular method used. The plant occupies 36 acres of land and is connected at both ends with the railroad on which it is located. Connections with city water mains provide water for plant operation and fire protection.

The storage yard in which timber is seasoned before treatment and which occupies most of the premises has a capacity of 600,000 cross-ties. As the average seasoning period is less than one year the storage facilities make possible the seasoning of sufficient timber to operate the treating plant to maximum capacity. The yard is graded to give thorough drainage and is covered with 6 in. of granulated slag to prevent the growth of weeds.

Ties are unloaded direct from incoming railroad cars to storage piles. When ready for treatment they are loaded on to tram cars which are run into the treating cylinder. Switching cars about the plant and handling trams to and from the treating cylinder is done with a 22-ton fireless steam locomotive that is charged from time to time with steam from the main boiler plant. Its use entirely eliminates all locomotive fire hazard, which is an important advantage, especially if creosote is used as preservative. All tracks are standard gage (4 ft. $8^1/_2$ in.). The use of standard-gage tracks throughout the plant not only simplifies its operation and makes possible the use of larger cylinders, thereby increasing the capacity of the plant, but it also reduces the investment in tracks and the cost of their maintenance.

gives an accurate and positive record of the amount of preservative retained in the treated timber and furnishes a check on similar determinations made during the process of treatment. Track-scale readings cannot be used, however, when treating green or partially seasoned timber on account of the loss of sap and water during treatment.

The tank equipment of the plant illustrated consists of two tanks for the storage of the preservative and smaller working tanks for the mixing, measuring and handling of the preservative during the treating operations. The storage tanks have a combined capacity of 200,000 gal. or sufficient to operate the plant for 45 days when treating with creosote at the maximum rate. In treating with zinc chloride less storage capacity is required as the preservative is received and stored in concentrated form, either as a dry salt or a 50 per cent solution. All tanks are of steel and are equipped with heating coils arranged to use either exhaust or live steam. Such heating facilities are necessary in the working tanks as the preservative, when used, must be at a temperature of from 130 to 200 deg. fahr. In the storage tanks less use is made of heat but it must be available because of the congealing of creosote at low temperatures. The working tanks used to prepare the zinc chloride treating solution are further equipped with steam jets through which live steam can be injected and the solution thereby thoroughly agitated and mixed and at the same time more quickly heated.

Cylinder Building

The cylinder building houses the equipment used in the treating process proper and is shown in plan in Fig. 2. The treating cylinder is $7^1/_2$ ft. in diameter and 86 ft. in length and is built to withstand a pressure of 250 lb. per sq. in. Its capacity is ten tram cars loaded with cross-ties or a total of from 450 to 640 ties per charge, depending on the size of the ties and whether they are hewn or sawn. The treating cylinder is open at one end only and is equipped with a heavy door made by riveting a dished-steel plate on to a cast-steel rim. The door swings on hinges and is equipped with heavy tee bolts which are fastened to and swing from the end of the cylinder and which drop into slotted holes in the rim of the door.

After completion of the treatment the ties are moved on the tram cars to a loading track where they are loaded into gondola cars with a locomotive crane. The crane is equipped with a large grapple which engages and lifts a tram load of ties at one time. At some treating plants the same operation is performed by a gantry crane and at some of the older plants the ties are loaded from trams into cars by hand.

MACHINING RAILROAD CROSS-TIES

By D. W. EDWARDS,[1] WASHINGTON, D. C.

THE cost of railway-track maintenance has vastly increased in recent years and one of the largest single items of expense involved in this work is the cost of cross-ties. Not only is their cost increasing with the diminishing supply of the most suitable timber and the growing scarcity of labor, but their life when unprotected grows shorter because of the greater destructive effects of heavier wheel loads and more frequent trains. Also the labor cost of renewing ties, exclusive of the value of the ties themselves, has advanced.

There are two causes of tie deterioration, decay and mechanical wear, and there is no economy in increasing the resistance to one without also increasing the resistance to the other. In some localities decay proceeds more rapidly than mechanical wear, and in arid sections ties wear out before they decay, but as an average the two destructive agents may be considered of practically equal importance.

It is evident that efficacy of treatment can be realized by doing all cutting before the treatment takes place so that the chemical may present an unbroken barrier to the attacks of decay spores.

[1] Greenlee Bros. & Co.

The majority of all ties are so winding or crooked that they should be adzed to secure proper bearings for the rails, but to do this after treatment is folly as it nullifies the effect of the treatment at the points where it is most needed, around the rail fastenings.

Trimming off the ends of ties by means of cut-off saws exposes internal decay which is not otherwise apparent because of the weather-hardening of the ends. A considerable percentage of ties are so decayed internally as to be of little value, and these may be thrown out before the cost of treatment has been expended upon them. This raises the average grade of the ties put in track and gives more uniform service. Trimming also increases the absorption of the chemical by the removal of the refractory case-hardened end surfaces.

Ties pass through the machines face downward and all operations are performed from below. Provision is made so the regular run of ties, large and small, straight and crooked, pass through as they may come and are automatically machined regardless of their irregularity of size and form.

Description of Machines

The double trim saw (Fig. 1) cuts about $^1/_2$ in. off each end of the ties. This removes the old hardened end wood, thus permitting better penetration of the chemical used for preservation, makes all ties of equal length, which makes for better and neater roadway, presents true surfaces for the brand, and principally discloses the condition of the internal state of preservation.

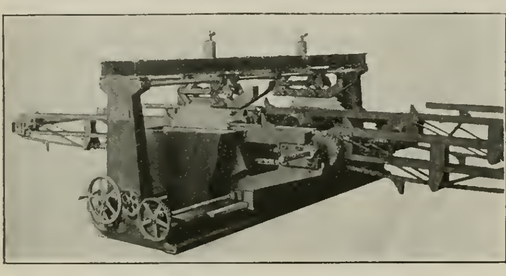

Fig. 1 Tie-Sawing or Trimming Machine

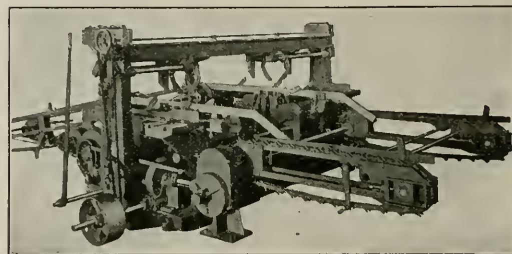

Fig. 2 Automatic Tie-Boring Machine

Briefly, ties are adzed to assure perfect rail-plate bearing; bored to permit chemical penetration, provide correct gage and perfect spike support; and trimmed for appearance and inspection. That the trimming operation is of the utmost importance and worthy of the most serious consideration cannot be too greatly emphasized.

Stationary Installations

For the complete four-unit type of trim saw, adzer, borer and brander, and with in and out tramcar tracks, skidways and conveyors, a building is required 66 ft. 6 in. long by 36 ft. 6 in. wide. The incoming tram track is 2 ft. higher than the outgoing one. This provides the desired elevation for unloading and reloading the trams in the mill and gives a down-grade pitch to the track for moving the empty tram cars around the mill by hand.

Trains of loaded tram cars en route to the treating cylinders are switched up the $1^1/_2$ per cent up-grade ingoing mill track. At the mill the track starts on a $1^1/_2$ per cent downward slope, passes through the mill on a return bend at the rear side and back to connect with the main line. Loaded trams are cut off the train and pushed on the down grade into the mill. When empty they are moved around the return bend to the delivery side.

Ties enter the mill in tram cars that stop in front of the skidways. A tram-car dumping rig removes the load of ties from the car and deposits it on the skidways. This consists of an overhead winch, driven by power, whose double capstans wind up chains securely anchored at their lower ends to heavy cast-iron abutments over which the ties are rolled by the tightening action of the chains. As the winch unwinds the chains lower and rest in slots in the floor, permitting the tram car to pass on.

The bales are removed from the tram cars just before the loads enter the front side of the mill. As the trams are unloaded they are moved around the circular track to the delivery end of the mill. Here they are reloaded and moved out to the front side of the mill where the bales are again applied.

The ties are halted in their fall down the skidways by railroad rails suspended from overhead. Two men, one either side of the skids, place the ties face downward in the correct endwise position on the machine's in-feed conveyors. The passage of the ties from this point through the machine is automatic and the trimming, adzing, boring and branding and delivery to the out-feed conveyors are accomplished mechanically. From the out-feed conveyors the ties drop into the outgoing tram car and are properly laid in place by two laborers. A loading form that outlines the bale circle assists the men in finishing off the load so the bales will fit in place when the loaded tram car leaves the mill.

The design comprises a heavy cast-iron base upon which are mounted housings that carry the saw arbors and feeding mechanism. The housings are gibbed to the base and are movable longitudinally upon it by means of large screws and a back-geared hand wheel. Each carries an independently driven saw arbor. The feed consists of two endless chains driven through speed-reducing gearing from the main countershaft.

The tie-boring machine (Fig. 2) is usually employed in combination with the trim saw and adzer, but there are some cases, such as work on sawed ties, where boring alone may be deemed sufficient. The feed is by means of a set of hinged and counterweighted dogs which are reciprocated by a cam and lever movement through worm and spur gearing. On the backward stroke the dogs pass under the ties, rise behind them and carry them ahead on the forward stroke. This intermittent feed gives time for the boring operation to take place upon the tie which is between the clamps.

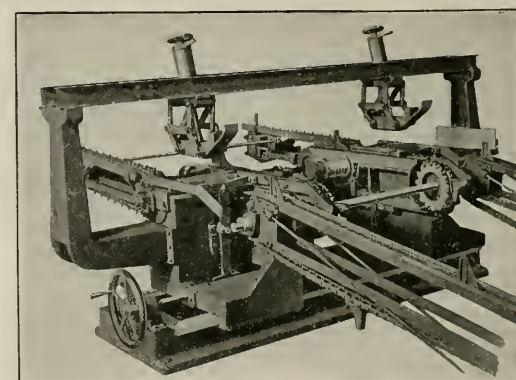

Fig. 3 Automatic Tie-Adzing Machine

A centering and clamping device holds the ties while the bits are boring, and automatically locates the holes so that the plate will rest correctly in the center of the available timber. This device consists of a pair of cam-operated spring-hinged centering and clamping jaws carried by the overhead supports and operated in unison with the bit-spindle feed. The centering jaws are assisted

of the available timber.

The bit spindles are arranged in two groups of two, three or four spindles each with adjustment between the groups for gage, and between the spindles of each group for different widths of rail bases and tie-plate punching. A tie-boring templet having hardened bushings for guiding the tie-boring bits assures correct boring.

The automatic adzing machine (Fig. 3) produces perfect plane surfaces at the points where the rails or tie plates will rest. The heavy cast-iron bedplate carries two housings, one fixed and one adjustable thereon. Each of the housings carries an independent arbor with a shear-cutting, expansion adzing head 11 in. in diameter and cutting up to 14 in. wide. The feed is by endless chains fitted with carrying dogs and driven by gears from the main shaft. A self-adjusting equalizing device which automatically raises or lowers one or both of the ways upon which the ties travel over the cutting heads so functions that the depth of cut is divided equally between the two ends regardless of bends in the tie, instead of the low end being cut much deeper than the other.

In-feed conveyors deliver ties from the skidways to the machine proper. The trim saw is placed first in the train. Saws 30 in. to 36 in. in diameter are used. The adzing machine receives the ties from the trim saw. The boring-machine feed moves them at an accelerated speed to the bits. There they pause, are centered, clamped and bored, and passed on to the brander which is placed to the rear of the borer. Out-feed conveyors pick up the ties at this point and deliver them to trams. These conveyors are fitted with an accumulator which when thrown in causes ties to be retained by the conveyor while the outgoing trams are exchanged. This provides time for the operators to dispose of a loaded and place an empty tram in position without stopping the machine feed; thus constant production is maintained. A shavings-removal system is provided. The machines are built with shaving chutes at each adzing head and group of bits, with flanges for connecting the piping leading to a shaving-exhaust fan. A cyclone dust collector is used where shavings are delivered in the open.

Portable installation is advantageous when plant conditions make it more economical to take the machine to the ties than to bring the ties to the machine. Also where the machine may be required only a part of the year in one plant and can be conveniently moved to another and thus be kept in practically continuous operation throughout the year.

The car which forms the basis of the portable outfit must be of steel underframe construction, 50 ft. long and of the greatest possible width, within standard clearance limits. The power plant is usually a heavy tractor-type internal-combustion engine. When the trim saws are included in the equipment a six-cylinder engine developing 90 hp. is employed. When the saws are not included a four-cylinder engine of 62 hp. is sufficient. Through a suitable transmission with lever control the engine drives directly to the tie machines or to the car axles giving a self-moving speed of about 100 ft. per min. for traveling about the tie yard.

To operate a tie-machining plant a crew of eight men is required, consisting of one foreman mechanic, his assistant, the machine operator and five laborers. Six to seven ties per minute are run and 2500 to 3000 ties per day are machined, or about 500,000 per year.

Discussion at Forest Products Session

Edgar U. Kettle opened the discussion with references to Mr. Park's paper on Engineering in the Furniture Factories. He stated it was his belief that Mr. Park's provisions for the handling and transporting of material would be more applicable to the old-time system of laying out a plant and that if his scheme were followed the comparatively small manufacturer would be obliged to carry a rather heavy overhead. He also referred to the fire risks involved in such a system and gave as his opinion that it would be more advisable to install a modern kiln.

H. C. Dickinson spoke of the large economic loss due to fatalities among workers. He stated that while a few states have passed effort will be made to have it adopted by the various states that there may be some uniformity along these lines. Codes for the logging and sawmill industries can be obtained upon application to the Bureau of Standards, upon which the Bureau is very anxious to obtain criticism from practical men.

Marion Cattermole spoke of the possibilities of applying automatic machinery to the processes involved in furniture manufacture and thus reducing to a very large extent the cost of manufacture. Very little had been done in this direction, he said, and in his opinion the possibilities were enormous.

The chair next called upon Mr. C. P. Winslow, director of the Forest Products Laboratory at Madison, Wis., who spoke of the work of the Laboratory both as regarded its efforts along the lines of conservation of the natural resources and of its value to the industries. Referring particularly to the work the laboratory is doing to assist the industries in solving their problems, Mr. Winslow discussed the question of assigning values for stresses of the various woods in use. This question, he said, depends upon the size and character of the logs and until the consumer realizes this fact and will insist upon securing the material by grades, the problem of safe working stresses cannot be settled upon. He also spoke of the attention that is being given to the question of standardizing the improved grades of lumber and to the work done on structural columns. The boxing and crating for the shipping of goods for domestic and overseas shipment is another problem receiving the attention of the Laboratory, said Mr. Winslow, and this work has varied all the way from the packing of machine guns for shipment to China to the packing of glass and cream separators, and has involved the question of the kind of nail, the type of strapping, the selection of wood, and the thickness for different commodities. Due to faulty packing the losses from this cause amount to as much as $100,000,000 a year. He also mentioned the work of the Laboratory in connection with by-products, particularly their coöperation with the manufacturers of paper and pulp. One of the most important phases of their work, he said, deals with the utilization of small material and there was considerable work being done toward the development of glues which would give joints not only as strong as the wood itself but also as permanent. If this were done he believed it would have an important bearing upon the economics of the woodworking industry.

Herman M. von Schrenk spoke both of the extremely wasteful methods employed in the woodworking industry and of the great need for proper understanding and full application of engineering methods.

Mr. Hall's paper on Electrically Driven Sawmills, brought forth a number of questions dealing with the type and size of motors employed and the power requirements for the various machines in use with the many types of wood encountered. To these Mr. Hall replied that induction motors were almost universally employed and that for a saw not larger than 54 to 60 in., 3-hp. to 4-hp. motors would be necessary. This somewhat indefinite statement was commented upon by Benjamin F. Tillson, who requested that Mr. Hall supply, if possible, more accurate information as to the precise motor sizes which were required for actual operating conditions. Grant B. Shipley also discussed the question of motor sizes and ratings and moved that the question of electrically driven sawmills be referred to the Committee on Woodworking for further study and that they should collect data concerning power requirements of various machines for cutting the different types of wood, not only for large but also for small sawmills. This motion was duly seconded, put to vote, and carried unanimously.

In a written discussion submitted after the meeting, G. B. Muldaur called particular attention to Mr. Winslow's remarks relative to the work done at the Forest Products Laboratory on the strength of wooden columns and the lack of definite data on the subject. Mr. Muldaur wrote that the Underwriters' Laboratories of New York had recently completed a most elaborate set of tests on columns of all classes, including wood, and that the results of these tests were now being compiled in book form and would be ready for distribution in the near future.

Policies for Future Power Development

The Demand for Central-Station Electric Power and How That Demand May be Met Economically—Conservation of Natural Resources and Labor

By COL. JOHN PRICE JACKSON,[1] PHILADELPHIA, PA.

The primary purposes of this paper are (1) to present the problem created in this country by the present acute shortage of central-station electric power, and the large growth of demand for such power; and (2) to set forth the physical, public, and financial relationships that appear essential for relieving the present stress and meeting the continually enlarging demand with reasonable economy and conservation of natural resources and labor. The first purpose is dealt with in the first half of the paper, and includes a comparison with the situation in England. Treatment called for by the second purpose begins with the heading Natural Power Districts, and extends to the end of the paper. The latter is largely an exposition of the possibilities and advantages of unified power systems for supplying the power required by natural power districts.

In a large industrial district with which the writer is familiar there is a large load ready and waiting to be connected with the central-station systems; and were there a wholly adequate and reliable supply of power at the disposal of the power companies in this territory, their present large aggregate load would be greatly increased. Expressed opinions of industrial and central-station men, as well as various statistics, justify the conclusion that an equally pressing situation exists in most or all of our important industrial centers.

The shortage of central power is serious by reason of the fact that it interferes materially with the natural productive growth of our country and with the prosperity of its several communities. Another even more serious element relating to such power shortage is the fact that it continues the use of a large number of isolated steam and electrical plants, most of which are consuming from two to four times the amount of fuel which would be required were the power supplied from efficient central stations. Moreover, the lack of sufficiently adequate central power systems makes impossible the economic utilization of many water powers which would become available if they could pump their power in the form of electrical energy into great electrical distribution systems having heavy demands.

To so develop the central power systems within a reasonably short time that they will meet the present deficiency, absorb the great amount of unconnected or isolated loads, care for the natural growth of demand, and utilize our fuels and water powers most advantageously, represents, in this country, a problem of gigantic dimensions which will require much wisdom to solve.

The English Situation

An even more striking situation affects England, where an acute shortage of fuel and inadequate development of electrical power had placed her, by 1917, in a position in which she was unable to keep up with the increased industrial growth demanded for war purposes. In this regard the situation was somewhat analogous to our own a year later, and is therefore of interest to us. The Board of Trade, a governmental body in England, appointed investigating committees of eminent engineers to study the situation and recommend programs for overcoming the difficulty.

As a result of these investigations it was found that enormous quantities of fuel were being ineffectively consumed by reason of the use of large numbers of comparatively small central stations, and by great numbers of isolated industrial plants.[2] The central stations also were unprepared to act in coöperation, and thus there were found in the area of greater London 70 concerns supplying electricity to the public with 70-odd generating stations, 50 types of systems, 10 different frequencies, and 24 different voltages.

As a result of these findings a bill was introduced in Parliament, which later became a law after modification of some of its compulsory elements. This law provides that there shall be a central body, known as the Electricity Commission, which is given wide powers relating to the national electric-power supply; that the British Isles shall be divided into large power districts in which electric-supply undertakings shall be "unified," the districting to be approved by further action of Parliament; that power boards composed of representatives of the power interests and others, shall be constituted in each of these regions; and these boards shall have charge of the operation of all power plants and transmission lines in their respective territories, including isolated plants, as well as the development and promotion of plans for expansions. It further provides for the transfer of central plants and transmission lines to the boards under certain conditions and gives them large powers of enforcement.

Direction of Development in America

Though the problem is much the same, the conditions in England differ in many ways from those in the United States, for here our commercial power companies have, of their own initiative, progressed far beyond those in England. In this country the growth of large, economical power systems is distinctly and actively under way with but relatively little direct governmental supervision. Furthermore, while English municipal ownership of power utilities has been actively growing, in America the commercial power systems have been developing with enormous rapidity. Again, during the ten years ending with 1917, America increased her central-station output from 123,000 to 241,000 kw-hr. per year per employee, with similar reductions in the use of fuel and other supplies per kw-hr., while in England the coördinate development has been relatively less satisfactory.

However, though the United States is in a better position than England, the demand here is insistent for even more adequate and reliable power systems, for the purposes of reducing at least the rate of increase of depletion of our natural resources, and for better conservation of our labor. To meet this very proper demand requires concerted action. Much has already been done in concert by way of coöperation and unification, but the time has come when more concrete and highly crystallized coöperative policies can be successfully determined upon by privately owned companies. Only by proper policies of this kind can such extensive governmental interference as has occurred in England be obviated.

As the United States is entering into the coming era of peace, indications are that it will face, in its foreign trade end and in its home market, a sharper competition than ever before from the other civilized nations of the world. Such competition is healthy and desirable, for it places us in a position where we must use every endeavor to produce along all lines with the greatest economy. This involves continued development of power production in the way which will most rapidly increase its efficiency in regard to the use of natural resources and labor, and at the same time provide, as far as feasible, a fully adequate and reliable power supply for all those in need of it, particularly for industrial purposes, wherever they may be located.

The Magnitude and Character of our Power Problem

The United States Geological Survey has recently tabulated the use of fuel for power purposes in the United States, based on estimates of 1919 power production and census figures.[1] It is estimated that 333,000,000 tons of coal were utilized in producing energy during 1919. Steam railways produced about 37.5 billion horsepower-hours and used 148 million tons of coal, or about 8 lb. per hp-hr. This includes the fuel for heating and auxiliaries. Manu-

[1] 1414 S. Penn Square., Mem.Am.Soc.M.E.

[2] Report of Electric Power Supply Committee (Cd. 9062), published in April 1919. (English.)

Abstract of a paper presented at the Power Section of the Annual Meeting, New York, December 7 to 10, 1920, of The American Society of Mechanical Engineers. All papers are subject to revision.

[1] Files of U. S. Geological Survey, Power Division, Sixth Ave., New York City (Henry Flood, Jr., Executive Secretary, under date of Nov. 1, 1920).

numerous, mostly small, plants at a cost of about 8.4 lb. of coal per hp-hr. In obtaining this figure, fuel used for heating in the manufacturing plants was deducted, but water power was included in the total horsepower-hour output. The fuel rate for the output of the steam apparatus alone was estimated to be about 9.8 lb. of coal per hp-hr. In addition to the above, there was produced by central power stations and electric railways about 53 billion horsepower-hours using 40.5 million tons of coal at a cost of 1.5 lb. of fuel per hp-hr. With water power deducted, this rises to 2.3 lb. for the steam plants alone. With our modern plants this figure is of course much less.

The field for savings in fuel that could be made were the aggregate of the loads named above furnished from efficient central-station systems is evident from these figures. A large part of the unconnected load undoubtedly can and will be rapidly connected for central-station supply, connection of other blocks will probably be delayed for economic or other reasons, and part is probably not of a character for economical central supply. Loads of the character of the last two will therefore delay or prevent obtaining the full savings in fuel which would be possible were our total industrial load supplied from economical central-station systems, but nevertheless possible practical savings are very great. In addition to savings in fuel, very material savings in labor also can be made by the extended use of central power systems.

The equipment, as given by the same reference, required to produce the energies named heretofore, amounts to about 100 million horsepower, including steam-railway locomotion, of which nearly 20 million are installed in central electric power stations and electric railways, and an approximately equal amount in manufactories. Included in this grand total, about seven and three-quarters million horsepower are of water-power equipment. Something less than a third of the central-station equipment is hydraulic, or about five and three-quarters million horsepower. Economic considerations will largely determine the rapidity with which this latter figure can be increased by further development of the available unused water powers of the country.

Census figures show that from 1907 to 1917 the output of central stations grew from less than six billion kilowatt-hours to over 25 billion, or more than doubled each five years. It should be noted, however, that electric railways are not included in these as in the former figures. During the same period the value of the central power properties increased from approximately one to three billion dollars and the annual gross income from about 1.75 to 5.25 hundred million dollars.[1] That this growth has been continuing is borne out by an extensive investigation, made by the writer with Henry Flood, Jr., Frederick Darlington, and others, of a typical American power district where the central power business had just about doubled from 1915 to 1920. It was also found in the same district that there was every reason to predict another doubling of the business in the period from 1920 to 1925 and further substantial increases thereafter. Available information leads to the conclusion that conditions similar to those of this district prevail throughout much of this country.

The above figures referring to the enormous expected central power demand, and other considerations, indicate that the following are among the most important activities to be undertaken in connection with the power situation as it faces the country today:

(1) To so design the construction and direct the operation of central power systems as to make possible the highest practical economy and conservation of natural resources and labor; and also to provide a fully adequate supply of power for all purposes.

(2) To so arrange by interconnection of transmission systems and otherwise that the maximum amount of water power may be developed. The amount of water power utilized can and will greatly increase with the rapidly growing power demands, but in many important industrial sections of the country, where water power is scarce, it will require much wisdom to cause the increase to become a greater percentage of the total power than now exists. Many watersheds having reasonably constant flow, however, but the consumption of fuel.

(3) To place steam plants, as far as possible, close to coal mines or on waterways in order that energy may be transmitted as much as possible in the form of electric power rather than in the form of coal, with resultant reductions of freight charges and relief to railroad traffic.

(4) To supply practically all industries with power from central power systems, which would result not only in an enormous coal saving, but also in a large saving in man power, maintenance supplies, and in transportation.

(5) To largely electrify the railways. This would make possible a great reduction in the fuel used for transportation purposes and relieve the railroads from carrying a large dead weight of coal freight for their own purposes, and also would make available the materially increased duty of railroad trackage and equipment which is possible by electrification.

(6) To not only make the central stations adequate for all of the above purposes and the expected future growth, but fully reliable.[1]

(7) To conserve a larger proportion of the valuable chemical constituents in the coal; such products are now recovered from only a small percentage of the total coal mined. Closely related with this problem is the conservation of our oil and natural-gas supplies. A discussion of these problems is not directly within the sphere of this paper, but it is believed that the suggestions for power development contained herein are along lines to coördinate with their solution. The problems are acute, for our oil and natural gas are showing signs of exhaustion, and though under present rates of consumption our coal may last a few thousand years, if the present increase in the rate of demand continues, it will be exhausted in a very limited time.

(8) To work out programs which will enable the financing of our power systems to be handled with facility. By the census there were three billion dollars invested in 1917 in the central-station industry, not including electric railways. About double that is needed now or as soon as the equipment can be produced, say, in 1922 or soon thereafter, and at least four times the 1917 capital will be required well before 1930 if reasonable progress is made.

The large sums of money indicated as necessary during the next few years for power development will in a large measure be spent even though no concerted effort be made to solve the power problem by a fully coördinated plan. But without concerted action there would be no possibility of such excellent returns, either in the form of earnings for the public and security holders, or in conservation of natural resources and labor. Were we advanced to a point of highly efficient central electrification of all power absorbers, with reasonable use of water power, the saving in fuel alone would amount to vast sums of money per year, with probable total savings of from two to three times as much if labor and all economies were included. The following suggestions with regard to power districts are intended to indicate the lines of a concerted policy of unification which would encourage these savings and at the same time accelerate central power development along the natural lines in which it is now advancing.

Natural Power Districts

The trend of power development during the past few years, and the present tendency, is toward the enlargement and unification of the power systems in large natural power districts. The boundaries of a natural power district are largely determined by the considerations that the region should be sufficiently large and the load of a character to enable it to sustain and properly use generating plants of a size and character necessary to give high economy, and at the same time have a territory sufficiently compact that the exchange of power between the several parts can be carried on conveniently and effectively. Due regard must of course be paid to the location and character of natural power resources. The actual area of a district to fulfil these conditions may vary

[1] United States Census, Central Electric and Power Stations, etc., 1917.

[1] J. W. Lieb set forth emphatically the need of "absolute continuity of service" in the discussion of Electric Supply at the meeting of the American Institute of Electrical Engineers in February, 1920.

widely; thus, the conditions of load, population, and natural resources demand a much larger territory for economical operation in California than is required by a district centering in New England.

A unified central power system supplying the power requirements of a natural power district inherently tends toward highly economical service, because such a system makes it possible to reduce to a minimum the aggregate amount of fuel used in the power plants through the possibility of raising the use of factors of the most economical plants of the region and lowering others, to take advantage of load diversities in the several parts of the district, to maintain a minimum of reserve equipment, to place necessary new plants at the points most effective from the standpoint of natural resources and the load, to more fully utilize water powers, and to permit a higher degree of reliability.

The selection of power sites for accessibility to coal mines, condensing water, water power, etc., has already become difficult with the present large stations and power demands, and with the great expected growth of these demands this problem will become more difficult. Unified action in a power district is of much value in this regard.

Those in charge of operations in a natural power district should design the unified system with the view to obtaining as far as practicable the same efficiency of production and delivery of power to all uses or users of power over the whole district, as is now attained in the big centers of power supply, if reasonably satisfactory conservation of our resources and the best welfare of our country and the power companies is to be obtained. It is evident that such objects require full standardization of voltages, frequencies, systems, etc., throughout the district, or better, throughout the whole country. Such standardization mostly exists in the United States, but it has not reached perfection.

At the present time the growth and unification of power districts is proceeding steadily, as may be noted by the situation in the New England States, the tying together of various companies and successful coöperation in western Pennsylvania and eastern Ohio, the getting together of a number of power companies in a group of the Southern States, in the unified control of the central-station systems of the Pacific Coast, etc. This kind of coöperative development was given a distinct and its most important impetus forward, during the war, by the Power Division of the War Industries Board, headed by Frederick Darlington, which was faced with the problem of relieving an acute shortage of both power and fuel, and the development of additional power to meet the rapidly growing demands caused by war activities. Mr. Darlington, after having examined the subject, concluded that the wisest procedure was to take advantage of and promote the natural tendency toward unification and coöperation of power interests in natural power districts, and with that object in view, dealt with several sections of the country as distinct units, or districts, including those referred to above.[1]

Experience during the war and various results found in peace times are sufficient to lead to the conclusion that both investment and operating costs will usually be so reduced by unification in properly limited districts as to make this kind of power supply attractive from the financial point of view.

UNIFIED POWER SYSTEMS

By the term "unified power system" (or unification) as used heretofore in discussing natural power districts, is meant a system in which the several component parts or companies combine and interconnect to obtain the efficiency and service which would be rendered if the entire district were operated by a single power company. Further, the terms used and discussions of the power problem herein are to be understood as confined to the generation and trunk transmission of power only, and not to include the distribution from the trunk-line load centers and its retail sale unless otherwise indicated.

The purpose and scope of this paper do not warrant entering into a discussion of technical engineering features, but the transmission of the power in quite large unified systems is feasible with existing equipment; thus, in a certain natural power district, a practical transmission system with switching and substations was recently laid out for a future growth to over a million and a half kilowatts. The technical work in laying out this system was largely done and was all approved by some of the best transmission engineers of the country. It is believed that projects which exceed this can be handled safely, though the difficulties to be met and the skill required for their solution should not be minimized.

The most simple method of handling a unified system, covering a natural power district, is by placing the entire generating and transmission apparatus in the hands of a single power company, either by purchase, lease, or the equivalent; where this is the condition no comment is necessary as to methods of operation or construction programs. Where it is not found advisable to arrange such a coalescing of the power companies the several systems of the several companies can be unified and operated as though they were under one ownership by the companies combining in the appointment of a power administrator, who is given full authority to direct the generation and delivery of power as he finds will result in the greatest economy to the entire district.

Where a power administrator is used, arrangements must also be made under which there will be an equitable distribution of earnings among the several companies. An example of a formal plan for accomplishing this is to have each integral company in the district compensated fully, with a reasonable profit, for its facilities in the way of power stations and trunk transmission lines with their substations, etc., which it holds ready for service. In other words, all company expense such as interest, depreciation, amortization, taxes, and insurance, with the addition of reserves and profits, constitutes readiness-to-serve expense for which the power companies are compensated. In addition to this, each company having generating stations or trunk transmission lines will be compensated in full for every operating expense incurred for power generated or transmitted under orders of the power administrator. The companies then pay for the power which they take from the unified system load centers, for retail distribution and sale, at rates per kilowatt-hour which, when applied to the aggregate power generated in the district, pay the combined ready-to-serve and operating charges named above. The price paid by a company for power purchased should, of course, have contained within it adjustments for load and power factors. The greatest difficulty entering into such a formal arrangement is the determination of the value of available facilities, but this need not prove an insurmountable obstacle.

A necessary corollary in this example is that the several integral companies in the district join together in laying out programs of construction in order that, as the load grows and additional stations and facilities are required, they may be developed in the way best to procure the highest economy for the district as a whole, and therefore, under the scheme dealt with, for each of the component parts.

In such programs of construction or in any arrangement of unification involving more than one company, it may readily be found advisable that the component companies join together in the development of a water power or the construction of a large steam power plant, say, at a coal mine, through the medium of a new company, or otherwise, rather than by settling the entire burden upon one of the component companies. A successful case of such joint action is to be found in the modern steam plant at Windsor, W. Va., on the Ohio River, built jointly by the West Penn Power Co. and the American Gas & Electric Co. through the agency of a third company created and owned by them.

Rather than have a single ownership, it may be found more advantageous in a natural power district to form a company which would make the interconnections, handle the interchange of power and settle the intercompany bills, as is done in Switzerland or at Windsor, or to work out other arrangements to meet the special conditions and needs.

It should be noted that the two companies at Windsor operate largely in different states, while the several interconnected companies in the entire power district in which they are located cover parts of Pennsylvania, Ohio, and West Virginia. Little difficulty has been encountered by reason of the crossing of state lines.

The idea of unification with a central power dispatcher, acting jointly for several companies in a district, is not a new one among engineers; as early as 1911 William B. Jackson, as the result of

[1] Report on the Power Situation During the War made by General Charles Keller to the Secretary of War.

and the possibility through it of reaching small communities not otherwise within the range of electrical supply.[1] Further, we have an example of a unified natural power district using a power administrator, which has proven satisfactory to the power companies within it and to its people. This is on the Pacific Coast, where the several companies have worked excellently in coöperation since 1918.[2]

For a recent period of power shortage accentuated by low water, unification arrangements were renewed by a written agreement among 17 power companies in Oregon and California, made last March before the State Railroad Commission, a part of which follows:

> We, the undersigned, hereby pledge that we will obey and carry into effect to the limit of our ability all rules, regulations, and orders of the Railroad Commission concerning diminution of service or taking on of new business, and interchange or delivery of power between the several companies.

The Railroad Commission was voluntarily selected by the companies as their agent and arranged to exercise the full powers, thus delegated, through a power administrator. There seems to have been no vital reason for having selected a public board as power administrator rather than any other person or body in whom the power companies and people have full confidence.

It is altogether to be expected that as unified systems in the natural power districts of the country develop, they also will find it advantageous to make interconnection for emergency and other services. In some cases it may be found that switching arrangements for connecting up the ordinary transmission lines in contiguous districts will be sufficient. In other cases it may be found that several unified districts can, to advantage, join together in the development of a large water power, say, such as on the St. Lawrence and Niagara Rivers in connection with the New England and Middle States, and part of Ohio, and perhaps in the building of a system of plants in the coal regions of Pennsylvania and West Virginia, for supplying more easterly territories.

W. S. Murray has suggested that some such arrangements may be desirable between the Atlantic Seaboard districts which he is at present investigating as the representative of the United States Geological Survey.[3] It should be added here that the investigation being carried out by Mr. Murray and his staff, as a bureau of the United States Geological Survey, is in response to a special act and appropriation of Congress. He has been given wide scope to study the present conditions of power utilization in a belt of territory bordering the northeast Atlantic Seaboard with its enormous industrial and railroad activities and to work out plans for electrical supply which appear advantageous. He has surrounded himself with a group of strong advisers whose joint judgment will be generally accepted. The findings will doubtless give another impetus to the use of central-station power and to unification.

Public Relationships

One of the most important elements which should be considered in bringing about the unification of a power district is that of proper relationship with the public. Effective joint publicity should be inaugurated which would make clear to the people of the district the value of unification, and the ways in which the public can serve to aid in bringing about such a condition of power supply.

The prosperity of every industrial community and of the nation is vitally dependent upon success in properly meeting the present and expected power demands of the country. There is every reason, therefore, to believe that redoubled attention, on the part of the power companies, to the subject of public relations—particularly if activities of this sort are under the direction of joint authorities for entire power districts—will create an adequate popular

[3] Economical Supply of Electric Power, by W. S. Murray et al, Midwinter Convention of the A.I.E.E., February 1920.

Special attention should be given to the development of laws whereby capital invested in power systems would be reasonably assured by law as to stability and return, instead of being subject to a modified status with every change of administration or public-service commission. One of our most capable and experienced financiers and industrialists in emphasizing this, recently said that, "Public-utility commission actions should be governed by definite laws". . . . "They should be bound to respect and recompense capital invested in public utilities according to plans definitely set out by enacted laws, so that the security to investors in railroads, electric power properties, gas plants, etc., would not be dependent on the personal attitude or judgment of transient commissions." Another man, also of high national standing, makes the statement that: "This is a government of laws and not of men, but there seems an increasing disposition to establish commissions not guided by any fixed or determined principles of law, but which have wide powers and whose decisions are frequently governed by expediency or opinion."

Laws should be enacted which would be as liberal in the matter of rights of way for power plants, transmission lines, and other needs of the power companies, as is the case for railroads or in various states with regard to water-power plants. It is particularly desirable also that the law be so drawn as to enable the power interests to share economies brought about by the ingenuity, energy, and capacity of their personnel.

With regard to this latter item it is well to call attention to the classical example of the South Metropolitan Gas Company of London, which is acting under a sliding-scale law. As the law stood in 1899, when the selling price of gas was not above 3s. 6d. per 1000 cu. ft., the return on the capital invested in the gas companies might be 10 per cent. (These figures have been modified, but the method is still in force.)[1] When the gas companies were able to reduce the price of gas, through economical operation, by a penny a thousand cubic feet, the return on the capital invested might be increased by $^1/_4$ of 1 per cent; increase of interest on the capital investment continued with each penny lowering of price, while raising of the price lowered the permissible dividend. It may be of interest to note that the returns on the capital gained under this sytem are so distributed as to give an incentive to the management and employees to make economies. A somewhat similar scheme is used by the Boston Gas Company of this country. The arrangement has the advantage of rewarding good service and at the same time bringing financial profits to the community. In the case of light and power companies the application of these methods is more complicated by reason of the varying rates charged for electric power, but the obstacles are not insurmountable and the principle is well worth considering.

The people of each power district should be brought into a closer relationship with the power companies by the distribution of securities to a maximum number of holders. If arrangements are made for payment in small installments and the stability and returns of the securities of most of our power companies are made known, there should be no difficulty in obtaining their wide distribution. Indeed, it is doubtful if there are many building and loan or savings bank associations which can show such excellent returns with reasonable safety as can our best organized electric-light and power companies. This, and obtaining financial support from large consumers, may not secure a major part of the necessary capital, but it will bring excellent returns in the nature of public support.

Financial Considerations

In order to procure the large amount of money necessary for obtaining adequate and reliable power in the United States, it is essential not only that the best plan be adopted from the engineering and business standpoints, but that it shall be one which is acceptable to the public and to public-service commissions. The plan must be one which will gain the definite approval of the latter, and the securities offered by power companies in obtaining neces-

[1] Report on Profit Sharing and Labour Co-Partnership in the United Kingdom, 1912. (English.)

sary funds should, as said, not only have the approval of the commissions, but be practically safeguarded as to earnings through stable action of the Government. The financial situation, under a properly designed unified plan for power districts with proper interdistrict connections, such as have been suggested, would better command the support of the public and protect their investments than would be the case were the necessary facilities installed and operated by several independent companies; in other words, there is undoubtedly better opportunity for such safety of investments and support by the public and the public-service commissions for a single well-worked-out plan covering a whole district, which would be clearly the right way of performing the work economically, than there would be for three or four different plans put on foot by several independent companies operating in one natural power district.

Since the success of the electrical power business in meeting industrial needs depends upon securing the necessary capital, this feature with regard to financing may easily be a controlling factor in the results. The power companies are practically obligated by their franchises and other contracts to supply the facilities needed to provide an economical and sufficient supply of electrical power. If they should not do this through failure to make the necessary financial arrangements, or for any other reason, the results which would naturally follow would be most unfortunate, and would probably lead to undesirable and in the end nationally injurious curtailment by the Government of the advantages of the strong personal initiative and incentive which now exist in the power industry of this country.

Discussion

Following the presentation of Colonel Jackson's paper at the Power Session of the Annual Meeting of The American Society of Mechanical Engineers, there was general discussion, the substance of which is presented below:

T. Kennard Thompson, who was the first to discuss Colonel Jackson's paper, stated that, as everyone knew, the greatest source of power in this country, and probably the most unified source of power in the world, was the Niagara River, and that by placing a dam four miles below the Falls nearly 200,000 hp. could be developed at a cost of not more than five dollars per horsepower. He exhibited some slides showing the site of this proposed dam and stated that power could be transmitted at 60,000 volts with a loss of only 10 per cent. According to W. S. Murray, he said, this voltage could be raised to 220,000 so as to transmit the power at least 500 miles, which would then take in both the Lake Superior and Quebec districts. It would thus reach 19 states of the Union and two provinces of Ontario, or 60 per cent of the entire population of the United States and 80 per cent of the entire population of Canada. Mr. Thompson also stated that it would be possible to develop other plants on the St. Lawrence and to obtain several millions of horsepower. If this were done, he said, Montreal would be one of the greatest seaports in the world.

E. H. De Lany suggested the founding of a Federal Bureau of Engineering and Research. "I think," he said, "that every technical bureau that has ever been inaugurated by the Federal Government has proved itself worthy, and has the support of the people." He urged the creation of the Federal Bureau on the grounds that no private corporation or society could afford to advance the funds necessary for experimental purposes and that such a Bureau could do a great deal more than either corporations or societies in the way of securing the legislation necessary to carry on its work.

John W. Lieb, in referring to Colonel Jackson's statements of the conditions in London where there are a number of plants with various frequencies and voltages, said that we face no such difficulties in this country because the systems in our great cities are fairly thoroughly consolidated. He called attention to the fact that the British Commission assumes control, not merely of "linking in," as the general term is there, but also assumes to say what type of installation an industry should use and also whether the industry ought to be allowed to instal such a plant or whether it should be made a part of a system which already exists. Furthermore, they assume the right to say what shall be the voltage and frequency in order that the proposed plant may form a part of the future prospective original system. Referring to capital expenditures and the availability of capital, Mr. Lieb said: "What the public wants is service, and the American public is willing to pay a reasonable and proper price for that service. But to obtain it, it must be possible to have adequate rates under proper supervision and regulation." Mr. Lieb also stressed the importance of the reliability of service, saying that it is absolutely essential in our great metropolitan centers to have absolutely reliable service, and that from an engineering standpoint a complete reliance on a transmission line alone, without an adequate steam stand-by, was not a safe and proper thing. The usual method of tying in and linking up of systems was also commented upon by Mr. Lieb. He urged the carrying of a joint reserve instead of each power company carrying its own reserve and meeting the capital charges thereon. "There is an important economic advantage," he said, "in having a joint reserve that is common to all." As to the tying in of systems, Mr. Lieb stated that what was necessary was not merely to have two original systems and then incorporate them by tying them together at the ends, but that the tie line should be of large capacity and should connect the systems at important generating points so that the load could be shifted back and forth at the points where it was needed. Mr. Lieb also referred to the work being done by the Superpower Survey and stated that if we wished as a nation to be leaders in industry we must go ahead with such comprehensive plans, which are essential to our economic national life.

Walter N. Polakov urged that the coal supply be conserved by utilizing distillation processes for the recovery of products now lost. We should put our coal, he said, through a low-temperature distillation process and thus obtain not only a smokeless, dustless, and odorless coal, but also certain gases valuable for domestic purposes and a residue valuable for fertilizers. Benzol, which can be used as a substitute for gasoline, as well as coal tar could also be obtained.

Harold L. Doolittle spoke of the systems now employed in California for the interchange of power. The scheme functions through the Railroad Commission and practically all of the companies in the state have agreed that future transmission lines shall be so constructed that ultimately a 220,000-volt bus line will run from one end of the state to the other and that in this way it will be possible to take advantage of any diversity in the load. Experiments have already been made on the line, he said, and there is no question as to the practicability of the scheme. In regard to economy of operation, he pointed out that there should be some method adopted which would reward public-service corporations for increased efficiency. To accomplish this in California, he said, the Southern California Edison Company had placed before the Railroad Commission the proposition of establishing some standard of operation, so that if any saving were made the corporation would be allowed to put that money in a fund. In other words, create a surplus, so that at the end of the year rebates could be made, 50 per cent to the consumer, 25 per cent to the stockholders in the company and 25 per cent to the employees. Mr. Doolittle stated that this proposition, however, had not as yet been acted upon.

W. S. Murray referred to the waste of power through the use of isolated plants and also by the railroads, and stated that the whole object and incentive of the Superpower Survey is to see that this may be corrected. Regarding the development of our waterpower, he said that the waterpower available in the superpower zone represents but a possible 15 per cent of the whole, and that therefore we must confine ourselves to a most careful consideration of the highest economic development of steam power. Mr. Murray also contributed a written discussion of Colonel Jackson's paper, extracts from which follow:

In connection with the railroads, the fuel consumption by steam engines against electric engines, respectively, in the passenger, freight, and switching service, has been shown to be 2, $2^1/_2$, and 3 to 1, and this with a thermal efficiency of the central stations driving them not greater than 8 per cent. Today the efficiency can be made to be 18 per cent, and this means that those ratios will be in excess of 4, 5, and 6 to 1. The best steam freight locomotive when burning 5 tons throws 3 tons away.

Mr. Henry Flood, Engineer-Secretary for the Superpower Survey, has placed in my hands a collaborated statement which shows that had the

coal, and as of 1930 the conservation that can be effected is estimated at 59,000,000 tons per annum.

These preliminary estimates of the savings possible through the centralization of power supply do not consider the complete electrification of the railroads in the district, nor the complete electrification of industry; for instance, on the heavy-traction railroads it is estimated that 6000 miles can be economically justified for electrification in 1920 of the total 30,000 miles within the region, and it is further estimated that the increase in electrification would grow only at a rate of traffic growth for this region up to the 1930 period, so that it considers the electrification in total by 1930 of only about 20 per cent of the total track mileage. In industry these estimates consider taking over to central power-supply sources only 50 per cent of the total power in the manufacturing industry, so that it is reasonable to state that these estimates are conservative and that they do not carry out the electrification of industry to the point of saturation.

Colonel Jackson points out the difficult situation in England with its innumerable small stations and varying frequencies. It is a lesson to us what we should avoid. Our plants are larger; our main frequencies are but two, and yet it is amazing to know that the capacity of the average-size plant in the United States is not greater than 3400 kw., and its consumption of coal per kilowatt-hour is 3 lb. The superpower stations projected will be on the order of 300,000 kw.; their economy should touch 1.5 lb. of coal per kw-hr. Again, a load factor of 40 per cent carried by a central station requires that station to burn 85 per cent of its coal before its kilowatt capacity has been taxed 35 per cent, and the remaining 65 per cent of its kilowatt capacity is used while burning the remaining 15 per cent of the coal. I think this visualizes what I have just said regarding the employment of the present large stations, which, if they are not in a position to furnish large blocks of kilowatt-hours, stand ready, however, as peak-load plants to furnish the capacity with which a very small amount of energy (kw-hr.) is involved.

Colonel Jackson says, "The time has come when more concrete and highly crystallized coöperative policies can be successfully determined upon by privately owned companies." I am in perfect accord with this statement, and I wish to emphasize at this point that the Superpower System as proposed stands alien to none, helpful to all, and that its construction will not be upon a competitive basis. The entity and franchise rights of the present central stations must be respected. The Superpower System through delivery and exchange will place energy upon the distributing mains of the present public utilities, and there its functions cease. Its duty will be the generation of a maximum amount of power for a minimum consumption of coal. It is to be purely a power and transmission company and will have no relations with the customers of power, except that those customers be public utilities.

Through the uneconomical production of power, coal is in the yards, on the sidings, and on the main lines of the railroads. It is competing with the raw and finished commodities for cargo space. Think what a saving of 59,000,000 tons of coal per annum in 1930 within a district between Boston and Washington, inland 150 miles, means! If that amount of coal is not required to be mined, first we have conserved nature's storehouse; second, we have relieved the railroads of its transportation and created cargo space for our other high-priced commodities which industry and expansion demand; and third, through the new process of power production as recommended in the Superpower System we will put a very large percentage of the remaining coal required for power and lighting in the form of electricity and thus create an overhead carrier system and automatically release cargo space for other important commodities.

Colonel Jackson's summation in the paragraphs of his paper numbered (1) to (8) is splendid, and the integration of these indeed furnishes an epitome of the specifications of the work undertaken by the Superpower Survey, viz.:

(*a*) Allocation of wastes and their amount, due to the present improper form of power production and distribution, and

(*b*) The recommendation of the regional plant through the means of which these wastes may be eliminated.

I am struck by his reference in Par. (7) to the average cost of a kilowatt installed by central stations up to 1917. This is $333, including the distribution system. In the past we have been required to build, due to the lack of interconnection, a plant and a quarter, the additional quarter being necessary for spare capacity. Through the proposed interconnection offered by the Superpower System, not only will this additional quarter capacity disappear, but through diversity the plant's capacity may be run below the 100 per cent line, and instead of our small plants (averaging but 3400 kw.) at a cost of possible $200 per kilowatt, the larger plants may be built at probably less than half that amount. Indeed, we have arrived at the period for the construction of enormous plants to carry the great base loads. The present unassociated load factor (and by unassociated is meant the independent operation of the industries and the railroads) now existing at 15 per cent will be lifted to 50, and thus it will not be difficult to visualize a 4,000,000,000-kw-hr. base load in a pool of power aggregating 36,000,000,000 kw-hr.

Colonel Jackson has said that special attention would be given to the development of laws whereby capital invested in power systems should be assured of a reasonable return, and in this statement he strikes a note of insistant requirement. Finance and engineering go together. It is indeed a case of E Pluribus Unum. Viewing the Superpower System from a commercial aspect and entirely apart from its basic and national importance, namely, the conservation of the millions of tons of coal pre-

The functioning of the Superpower System is within the limits of power generation and transmission. It ends where distribution begins. If it can furnish a kilowatt-hour to a local company by the expenditure of two pounds of coal where the company has been burning three pounds, it is reasonable to expect that such a company would take the power so delivered to its distributing lines, particularly when it can obtain such power with a relatively small investment, smaller than it would have been in providing its own facilities to produce the power at such a low coal consumption. In fact, there are many distributing companies so located that it is absolutely impossible for them under any condition at the present time to reduce their coal consumption much below their present figure.

Wm. B. Jackson called attention to the fact that by the development of interconnections and of network transmission circuits it would be possible to utilize many water-power sites which might otherwise remain undeveloped. Furthermore, with a reliable transmission system it would be possible to reduce the investment in steam-power stations because of the fact that the maximum capacity of the water-power plant will always be available and consequently can always be operated at maximum capacity. Mr. Jackson also discussed other factors in the development of hydraulic stations, touching upon such points as more effectual operation of the existing steam plants, coal savings, load factors, and capacity of transmission lines.

Charles W. Thomas referred to the newly created Federal Power Commission and its duty of granting preliminary and permanent licenses for the exploration and final development of water powers. He said that in his opinion influence should be brought to bear upon the Commission so that permanent permits would not be issued to those who might finally develop important water-power sites in an incompetent way.

Henry Harrison Suplee, referring to flood control of great rivers, particularly the Mississippi, the Ohio and its tributaries, stated that it had been suggested that by controlling the run-off rainfall much nearer the source and by supplying proper catchment basins, power could be developed, while at the same time losses due to floods could be entirely avoided. Mr. Suplee also spoke of the difficulty of securing local interest in one part of the country for the benefit of another and suggested that it would probably require a Federal bureau with appropriations from Congress to develop such a scheme.

H. P. Quick contributed a written discussion in which he reviewed the method of financing hydroelectric enterprises that have been built in this country, Canada, Mexico, Brazil and Spain, by money furnished partly by bankers, partly by capitalists, and partly by small investors. The promoters of these enterprises secured their money, he said, by first getting a majority control of existing going enterprises and future consumers of their power, and then issuing bonds and selling stock in new development companies, or railway, light and power companies organized for the purpose of hydroelectric development and power distribution in the various municipalities. These bonds and stock were sold as the reconstruction or improvement of the going concerns or as the new construction demanded and the revenues increased with which to pay interest on the bonds. Of course the purchase of stock or the gift of stock having great prospective value increased the income of the concerns, and the ability, standing and character of the managing engineer-president-financier and his associates furnished the additional incentive to investors to open up.

As to the attitude of American bankers toward such enterprises Mr. Quick wrote as follows:

Did American bankers assist to any great extent in these developments of foreign enterprises? Not a bit of it, and perhaps they were wise in view of the revolutionary possibilities and actualities in some of these countries in recent years. But plenty of foreigners—Canadian, Englishmen, Frenchmen, Belgian bankers and others invested in them, as they saw a large profit and thought the countries stable and were accustomed to such investments.

Now, if those same developments had been undertaken by the foreigners' own nationals, how would the undertakings have been financed? Why, by their governments, by securing control of going enterprises, or by special taxation of utilities or communities to be benefited; and this revenue or taxation, or perhaps the revenue from imports and exports, or the income from foreign stocks and bonds as collateral, would be used or set aside periodically to pay the interest on new government bonds issued

(*Continued on page 110*)

Effect of Load Factor on Steam-Station Costs

By PETER JUNKERSFELD,[1] BOSTON, MASS.

The following paper discusses the factors affecting steam-station costs, particularly the load factor. Financial loss, the author states, will result whenever it becomes necessary to operate a power station at a substantially higher or at a substantially lower annual load factor than that for which the station was properly designed. The load factor should be carefully considered in locating a central station as well as in the selection of equipment. Fuel, usually an item of great expense, is dependent upon the load factor, the efficiency in the use of fuel being greater at the higher load factors. Curves are given to show relative generating costs and boiler rating as affected by load factor, typical week-day load curves and load factors, and the load factor as it occurs from day to day and month to month.

The annual load factor is an indication of the number of hours per year that the dollar of capital expenditure in a steam station can be kept at work. The expense of using this dollar is just as great when it is working 100 hr. as when working the full 8760 hr. of the year. The returns are, however, in direct proportion to the number of hours per year that this dollar is kept at work, or in other words, to the annual load factor. For example,

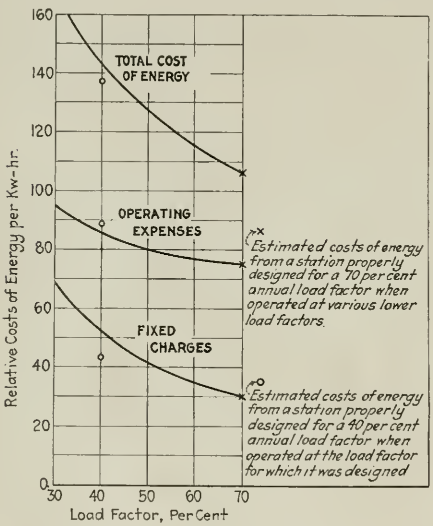

Fig. 1 Relative Generating Costs, Showing the Effect of Designing a Station for Too High a Load Factor

if the annual load factor of a power station is increased from 30 per cent to 60 per cent the fixed charges per kilowatt-hour are cut in half.

Load factor is the ratio of the average to the maximum output during any definite period of time. It is usually based upon an average demand for, say, 15 min., and upon output for a day, week, month, or year. It may apply to a system having many generating stations and serving many communities, or merely to one power station or even one unit in a power station.

The annual load factor of a central-station system nearly always changes very slowly. Special effort to secure a well-diversified business together with the new uses of electricity which are constantly arising contributes substantially to improvement in load factor.

The ordinary factory, working a 44-hr. week with the usual lay-offs for holidays, keeps a power station busy for only one-quarter of the 8760 hr. per year. Residence and street lighting tend to improve load factor in the summer, but are less and less of a help as the days grow shorter, until they finally change from a blessing to a burden upon the plant, during the months when the lighting peak overlaps the end of the factory or business day.

Investment as Affected by Load Factor

The cost of energy is made up of two principal elements, the fixed charges and the operating and maintenance expenses. In the case of the fixed charges we must use annual load factor because fixed charges run on year after year. Suppose that one power station has cost \$100 per kilowatt. At 15 per cent per annum the fixed charge per kilowatt would be \$15 each year. With an annual load factor of 30 per cent, the fixed charge per kilowatt-hour would be 0.57 cent. If the load factor is increased to 70 per cent, we find this fixed charge per kilowatt-hour cut to 0.24 cent.

This comparison of course is not wholly a fair one, because a station properly designed to operate at a 70 per cent load factor would cost more to build, although less per kilowatt-hour to operate, than one of equal capacity but properly designed for a 30 per cent load factor. Its boilers would have been rated differently, turbines of different individual capacities and perhaps different efficiencies might have been selected, the condensers would have been designed more liberally and higher-efficiency equipment would have been selected wherever economical with the higher load factor. Even supposing that those features boosted the first cost \$20 per kilowatt, we would still save probably one-tenth of a cent per kilowatt-hour in the combined fixed charges and operating expenses in comparison with an attempt to impose a 70 per cent load factor on a plant properly designed for one of 30 per cent.

The curves in Fig. 1 show the relative costs of energy from a power station designed for a 70 per cent annual load factor when operated at various other load factors. Note at 40 per cent annual load factor the lower cost of energy obtained from a station designed for a 40 per cent annual load factor. The lower fixed charges on the 40 per cent station more than offset its higher operating expenses.

Financial loss will result whenever it becomes necessary to operate a power station at a substantially higher or at a substantially lower annual load factor than the annual load factor for which the station was properly designed. Suppose that the station mentioned previously were one of several stations supplying a light and power system. Assume that at the time of its construction it were intended to operate it on a base load at a 70 per cent annual load factor, whereas the other stations supplying the system were to be operated only to carry peak loads on account of their inferior efficiency. Assume also that within a few years on account of rapid growth of load another larger station, not previously contemplated, were built having greater efficiency and that the station first mentioned no longer were operated on the base load but were operated at a 30 per cent annual load factor. We at once see that we are then using an unnecessarily expensive tool where one costing \$20 less per kilowatt would do the work just as well and at less total cost per kilowatt-hour.

Similar financial losses may occur in a single power station supplying a rapidly growing load. When a new unit is installed in a power station it is important to know approximately how soon another will be required. Each succeeding unit is frequently larger than the preceding ones, up to the practical limit of size available for the particular purpose. The increased size is usually accompanied by increased efficiency. The units of highest efficiency carry the bulk of the load. The extra price paid for extra efficiency in a power-station unit sometimes results uneconomically due to another larger unit being installed earlier than anticipated.

The cost of an error of judgment or the extra expense due to an unexpected change in the annual load factor at which a station or unit is operated may therefore be considerable.

[1] Stone & Webster, Inc., Mem.Am.Soc.M.E.

Abstract of a paper presented at the Annual Meeting, New York, December 7 to 10, 1920, of The American Society of Mechanical Engineers. All papers are subject to revision.

The location of a central station relative to its raw material supply and to the point of delivery of its finished product should be influenced greatly by load factor. In the selection of a site, condensing water is usually given first consideration. Transporting it adds greatly to the station fixed charges, while cooling it artificially causes inefficient operation. A very low annual load factor, likely to prevail over a long period of years, sometimes justifies artificial cooling of condensing water if the station may thereby be located near the load with a minimum investment in transmission lines or cable. With a large annual load factor the additional operating expense due to cooling the condensing water might be so large as to entirely outweigh the fixed charge on the transmission line so that the plant would be located where condensing water is available. In weighing the relative costs, the operating expense at either location must be added to the fixed charge before the more advantageous site can be determined.

Selection of Equipment

Load factor determines the quantity of fuel consumed by a power station and has considerable influence upon the efficiency with which it is burned. Starting, stopping and standing by as well as operating equipment only partly loaded, as is required at low daily load factors, inevitably result in a high coal rate.

One of the first problems, if the station be a new one, is to determine the boiler pressure. High efficiencies can be obtained with high boiler pressure. Construction cost, on the other hand, increases rapidly with increases in pressure. The economical pressure should usually be determined by the extent of the use of the equipment, that is, by the annual load factor.

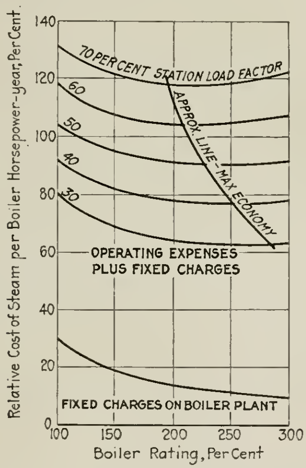

Fig. 2 Boiler Rating as Affected by Annual Load Factor on the Station

An arbitrary assumption of steam pressure or an arbitrary selection of certain principal items of equipment may so definitely restrict the design that the full financial benefits of a consideration of load factor in the later selection of additional equipment may not be realized. The most far-reaching power-station engineering is done during the conception of the project, and it is at this time, when fundamental decisions are being made which will either help or hinder the engineering construction and operation of the station, that load factor should be given the greatest consideration. This means not only the immediate load factors but also the load factors that could reasonably be expected during the probable life of the equipment.

Reference has been previously made to the differences in boiler rating for which central-station boiler plants would be designed for operation at different annual load factors. This depends upon the cost of the boilers and combustion equipment, their efficiencies at various loads, the cost of labor and maintenance at various load factor on the most economical rating at which boilers should be operated to carry the station peak load. Note the manner in which this economical rating increases as the load factor diminishes.

The rating is only one of a number of boiler-plant problems that arise which must be solved on the basis of load factor. The type and design of the boiler, the length of its tubes, the number of rows of tubes wide and the number of rows high, the combustion equipment, the location of the bridge wall and the baffles, and the size and shape of the furnace, should all be determined by reference to the total load factor on the station as well as the anticipated load factor on the individual boilers. The use of economizers even in large stations cannot be justified at very low load factors.

The economic selection of turbo-generator units may be made upon the basis of size, speed and other factors. The speed influences both the cost and the efficiency of the unit, and is very important in relation to the average annual load factor at which the machine will operate over a period of years.

The selection of a surface condenser should be made largely from the point of view of the annual load factor. A high load factor anticipated for a unit for a long period of time would justify

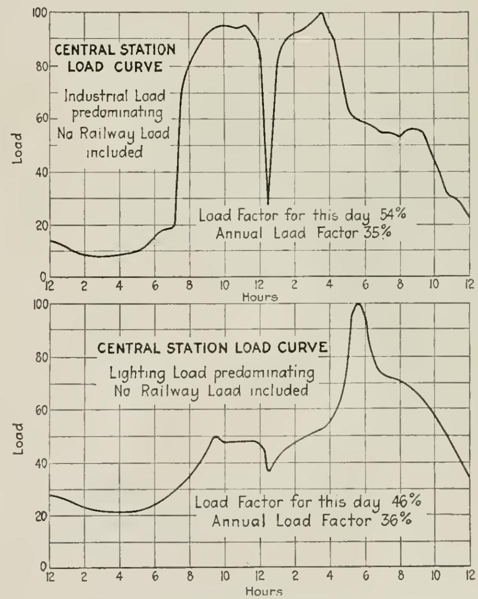

Fig. 3 Typical Week-Day Load Curves and Load Factors

a condenser of large surface so as to obtain a high efficiency in operation.

The foregoing does not attempt to mention the many power-station appurtenances contributing to higher efficiency which should be omitted from the station designed to operate at low annual load factor, but which might be justified if the station annual load factor were higher. On the other hand, it should not be overlooked that there are some instances in which it is more economical to buy more expensive equipment for low load-factor conditions than for higher load-factor conditions.

The engineers who design a power station fix the upper limit of its operating efficiency by the selection and arrangement of equipment. If this is properly done for the particular load and load factor, the total cost of power from that station, including the fixed charges upon the investment, will be a minimum if the station is properly operated and maintained. If the selection and arrangement are not made wisely the station thereafter will be handicapped either by excessive fixed charges or excessive operating expenses.

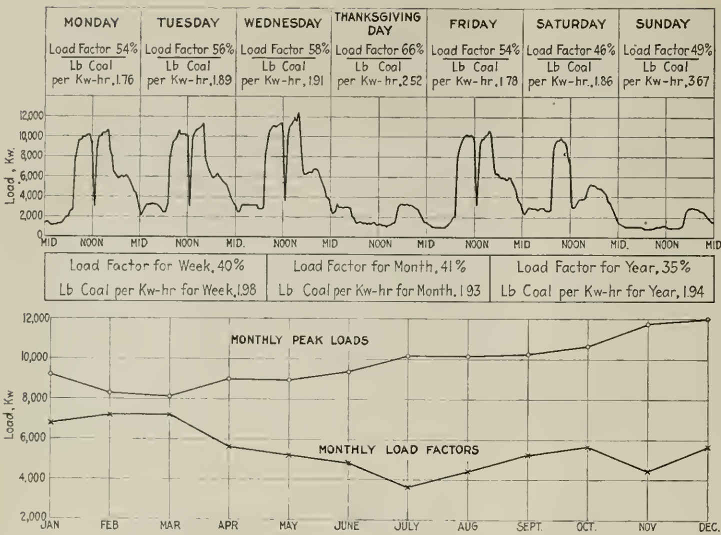

Fig. 4 Load Factor as it Occurs from Day to Day and Month to Month

Operating Expenses

The expense of superintendence and station administration is more or less fixed for a given size of station so that a change of load factor would not influence it in total amount. Boiler labor may be considered as composed of two parts, one of which depends upon the capacity of the station alone, and the other of which, for a station of given capacity, would vary with the daily load factor upon the station. Mechanical labor would be influenced by daily load factor to a less degree but would depend upon the number and size of the main generator units. The electrical labor would be influenced more by the number of feeders or the number of kinds of current distributed than anything else.

Fuel is usually an item of greater expense than all others and, as pointed out previously, it is dependent upon load factor. Efficiency in the use of fuel is greater at the higher load factors. As an example of the effect of load factor upon station operating expenses, a hypothetical case may be taken of a station containing units of various sizes which might have operating expenses as shown in Table 1. Note the fuel expense as compared with the total.

Load factor alone does not by any means determine the amount of fuel which a central station of a given size should consume. The shape of the daily load curve is of almost equal importance in its effect upon the efficiency with which the fuel is burned. The shape of the load curve is in turn dependent upon the character of the business served by the central station. This is illustrated by the two examples of central-station load curve given in Fig. 3. In both instances the lighting peak overlaps the day load, but on account of the predominance of factory load in the business of one of these stations an exceptionally favorable shape of load curve is obtained as well as a relatively high load factor for the day.

Table 1 Operating Expenses as Affected by Load Factor

	Operating Expenses, Cents per kw-hr.		
Annual Load Factor, per cent	30	50	70
Fuel	0.91	0.85	0.71
Labor for Operation	0.10	0.07	0.06
Maintenance, Material and Labor	0.08	0.05	0.04
Miscellaneous, Material and Labor	0.04	0.03	0.03
Total	$1.13	$1.00	$0.84

It is interesting to note, however, that the load factor for the year is practically the same in these two cases. This is due to the effect of the extremely low loads which obtain on Sundays and holidays. For these two conditions, illustrated by Fig. 3, having practically the same annual load factors, the better annual coal rate would be obtained with the one having the more favorable shape of load curve, that is, with the one in which the factory load predominates.

Fig. 4 shows how the load and load factor vary from day to day and month to month for a business in which factory load predominates. The beneficial effect of high load factor on Thanksgiving Day, for example, is much more than offset by the relatively small load on the station on that day. Note how the load factors for the week and for the month are practically the same. The load factor for the year is somewhat lower due to the variation in maximum demand throughout the various seasons. In general the better coal rates are obtained with the higher load factors, although this is greatly influenced by peak load, quality of fuel, and skill in operation, all of which are interesting subjects but beyond the scope of this discussion.

Discussion

In the extended discussion at the Power Session of the Annual Meeting, those whose remarks dealt more particularly with Mr. Junkersfeld's paper were Messrs. Charles Penrose and James T. Enes. Mr. Penrose stated that it is perhaps the foremost duty of the engineer to act as conserver of the natural resources and to obtain the greatest possible economy in power-station design. If this is true, he said, then instead of designing a power plant for existing loads it should be designed for abnormally high loads and then the load should be developed. This could be secured by a combination of circumstances and loads, including railroad electrification, street-railway load and industrial uses. There has been secured, he said, within a short radius from New York City a load factor which at the present time, exclusive of Saturday, Sunday and holidays, has the high figure of 78 per cent.

Mr. Enes referred to the relation between the investment and load factor, which in turn depends upon fixed charges and operating expenses. Since we are now entering a new era of increasing prices, he said, it will be very difficult and perhaps impossible to determine such charges. We have in mind prices and the actual value based on the entire life of the plant. The problem is thus complicated because of the fact that we are now entering upon a period of increasing prices.

POLICIES FOR FUTURE POWER DEVELOPMENT

(Continued from page 107)

to bankers of other nations who would take them and sell them to their customers, clients, stockholders, etc., or they would be taken by the construction companies and sold in the same way.

Now that fact of government-issued bonds with guaranteed income at high rates of interest from the start is the inducement that leads the United States bankers to take the securities of foreign stable governments, as they have been doing recently, which funds are to be used for hydroelectric developments that will enable electrification of railroads and industries, and make great savings in fuel. For, what bankers are as a rule looking for is securities that they can take at a profit and recommend to constituents as a profitable investment, either from their own investigation or that of the governments or municipalities they represent.

I believe the United States Government or its Federal Power Commission must do as the foreign governments are doing in order that the funds may be raised for these enterprises. In other words, having sanctioned the enterprises, issued licenses, fixed the rates for interest and for power, guaranteed the efficiency and caused the cost or value to be filed with it, they must go further and find the funds to develop by first finding or arranging for the money to pay the interest, then issuing the securities to be sold to bankers, and they in turn to investors, on the strength of Government backing and guaranteed interest from the start.

Those who provide the money for interest, through taxes or assessments, must expect to get it back in some way, either through enhanced values of property, or improvements, lower rates, cheaper power, etc. The Commission will then have to regulate the use of funds during construction by the engineers and contractors, and lease the enterprises to operating companies for the term of years, specified in the Act.

By E. B. Rosa,[1] Washington, D. C.

The United States Government is carrying on a very considerable amount of scientific and engineering work through a large number of bureaus located in several different departments. The Agricultural Department is sometimes spoken of as the greatest scientific institution in the world. The Geological Survey, the Bureau of Mines, the Reclamation Service, the Bureau of Standards and other bureaus are well and favorably known for their scientific and engineering work. The importance and economic value of such work is only appreciated by engineers and others who have been brought into intimate contact with such work. Our industries and our civilization are largely based on science and its manifold applications, realized in practice through the various branches of engineering. That the Government should foster science and engineering and cooperate with and develop the industries by means of scientific and engineering research is very generally admitted. There is, however, in the mind of the general public a feeling that this work is not carried on as successfully or as efficiently as it should be, that its distribution and its management could be improved, and that it probably costs too much. This feeling finds expression in the press quite frequently these days, and in terms which lead one to believe that there is a good deal of misunderstanding and misconception regarding the scientific work of the Government, its scope and value and cost. The author has therefore thought it worth while to make a rapid survey of what the Government is doing in the way of scientific and engineering work, how and why it is doing it, what it costs to do it, and, if possible, to answer the question, does it pay?

SOME months ago the writer made a study of the appropriations for all branches of the Government service for the fiscal year 1920. These appropriations were analyzed and classified into six groups.[2] The result showed that for the fiscal year 1920, 3 per cent of the total budget was appropriated for general governmental purposes (legislative, executive, and judicial), 3 per cent for public works, 1 per cent for research, education, and development, and 93 per cent for the army and navy, railroad deficit, shipping board, pensions, war-risk insurance and interest on the public debt, all of which are either obligations arising from the war or for preparation for possible future wars.

In order to get a more accurate knowledge of Government expenditures, and to ascertain how they have increased in recent years, the receipts and expenditures of all departments for the past ten years were analyzed, using the official published records of the Treasury Department for the purpose, but following a somewhat different and more detailed classification. Appropriation bills do not show the earnings or credits to bureaus and departments and hence in many cases are misleading as to the real cost of a given branch of the service. In some cases the whole cost, and in other cases a large part of the cost, is covered by fees or earnings. Examples are the Consular Service, the Patent Office, the Land Office, the Reclamation Service, the Bureau of Navigation, the Forest Service, National Bank examinations, the Federal Reserve Board and notably the Post Office. A "billion dollar Congress" was a familiar phrase in prewar days, but this did not mean that the National Government cost the taxpayers a billion dollars a year. It meant merely that the gross annual disbursements of the Government, including the entire business of the Post Office Department, amounted to a billion dollars per annum. In no single year prior to our entry into the Great War were the net expenses of the Government as much as seven hundred millions of dollars. The important distinction between gross disbursements and net expenses is too obvious perhaps to be emphasized, but it is often overlooked. This study has yielded results of very great interest and value, and throws much light on the question of the cost of government, and whether the civil side of the Federal Government is overdeveloped, and to what extent it is a burden upon the taxpayer.

The Classification Adopted

In order to obtain the relation between the scientific and engineering work of the Government and other Government activities, both as to distribution and expenditures, we may review briefly the organization of the Government, which for the present purpose may be divided into two parts, the civil and the non-civil. The civil side of the Government may be divided into three groups of departments or activities as follows:

I Primary Governmental Functions
II Research, Educational, and Developmental Work
III Public Works (New Construction).

The remaining activities may be grouped as follows:

IV Army and Navy
V Pensions and Care of Soldiers
VI Obligations Arising from the Recent War
VII Interest
VIII Public Debt, Loans, and Trust Funds.

Lastly, Group IX includes all revenues of the Government which are derived from direct or indirect taxation.[1]

Disbursements, Receipts and Net Expenses for Ten Years

In order to obtain a correct idea of the actual expenses of the various departments and bureaus of the Government, it is necessary to take account of their earnings and of credits for the sale of Government property, trust funds received and disbursed and of unexpended appropriations turned back into the Treasury. The Treasury Department publishes each year a Combined Statement of Receipts, Disbursements, Balances, etc., of all departments for which appropriations are made, as well as of revenues collected, and these official publications have been used in this study. The ten fiscal years, 1910–1919, inclusive, have been taken, the report for 1920 not being available as yet.

In some cases appropriations greatly exceed actual net expenses, and, on the other hand, certain continuing and indefinite appropriations do not appear explicitly in current appropriations. Fees and fines, proceeds from the sale of Government property and other collections are turned into the Treasury and recorded under miscellaneous receipts, and cannot be expended by the department or bureau collecting them. During the fiscal years 1910 to 1917, inclusive, the amounts of these miscellaneous receipts ranged from forty-five to eighty million dollars each year. In the two war years, 1918 and 1919 taken together, they amounted to over nine hundred million dollars, including several hundred millions for interest on loans to European governments. Expenditures and receipts are distributed among the 106 items of the eight groups, and net revenues and net expenses determined for each item and each group, and the whole added and balanced and checked against the figures given in the summaries published by the Treasury Department. For each year a summary statement was also made for Group IX showing the revenues collected through the customs, internal-revenue taxes, and taxation of national-bank circulation. These are the only revenues resulting from taxation; fees and fines and the proceeds of sales of Government property being credited to departments, as stated above, as an offset to expenses. For example, the fees collected by the State Department or the Patent Office or the Land Office, or the Bureau of Navigation, or a federal court are not intended as taxes for governmental revenue, but rather as fees to cover in part or in whole the expense incurred in rendering a special service or adjudicating a specific case, or as an administrative measure, and are properly credited against the expenses of the given agency. Most, if not all, of these agencies perform public functions and thus render a service to the public as a whole apart from the service to individuals for which a fee is collected. It is thus proper that the public as a

Presented at a Meeting of the Washington Section of The American Society of Mechanical Engineers, December 2, 1920.

[1] The detailed classification adopted is given in the Appendix.

whole should pay for the general service to the public if the individuals served pay for the individual service which they receive. But it is obviously unfair and misleading to charge against a department or bureau the entire expense, and not credit to that department or bureau fees and other earnings or receipts from Government property sold, all of which have caused the expense to be greater than otherwise.

An extreme case of the kind is the Post Office. The Postal Service account is kept separate from the General Fund of the Treasury, and includes all the receipts of post-office business and all expenses other than salaries for the central administration of the Post Office Department, and certain items of a general character. In addition to these overhead items paid from the Treasury, which amount on the average to less than 1 per cent of the postal revenues, the net deficiency or net surplus is transferred over to the General Fund of the Treasury in a single item each year. During the last ten years the total of the surplus transferred amounted to $26,033,448, and the total of deficiencies amounted to $30,890,619. This is in addition to $110,000,000 special war revenue collected while 3-cent letter postage was in vogue. The excess revenue resulting from the extra cent charged, which was regarded as a war tax, was transferred to the General Fund.

The expenditures on the Panama Canal while under construction were included in the Public Works group, but after its opening the cost of routine operation and maintenance together with tolls collected were placed in Group I, while the cost of additions and betterments was included in Group III. The cost of the fortifications of the Panama Canal, however, has been charged in this study to the War Department as a military expenditure. On the other hand, the large sums spent for river and harbor improvements, which are expended by the Army and charged to the War Department in the Treasury account, have been charged in this study to Public Works, on the ground that these improvements are for civil rather than military purposes.

The Reclamation Service has annual appropriations of about nine million dollars, bu it is provided that it cannot expend any more money than is received annually through the sale of public lands and by collections from settlers for lands they occupy or for water received by them for irrigation purposes. Thus the nine-million-dollar appropriation to the Reclamation Service is only an authorization to use the money which they annually collect, or which has been turned into the Treasury by the Land Office, and hence the Reclamation Service costs the taxpayers very little. Some years ago $20,000,000 was, indeed, advanced to the Reclamation Service as a loan, in addition to the receipts from land sales and collections from irrigation projects. This has all been expended and this year a first installment of one million dollars will be paid into the Treasury toward the liquidation of the loan.

The Treasury Department maintains a large force of national-bank examiners, and expended in 1919 more than a million dollars for their salaries and expenses, but it collects and reimburses the Treasury for every dollar of it through assessments upon the banks. It also collects nearly a half a million dollars a year from national banking associations on account of salaries and contingent expenses of the Treasurer of the United States and

this sum was the Indians' own money, which the Government handled as trustee for the Indians. Only $10,500,000 was borne out of taxation as an actual expense to the Government. These examples are given to illustrate the important distinction between gross disbursements and net expenses of the various departments of the Government.

RESULTS OF THE STUDY

The results of this study have been collected in the form of numerous tables which have furnished the data necessary for the preparation of a number of charts, which graphically illustrate the results obtained. A few of these charts are reproduced here. This study covers the fiscal years, 1910 to 1919, inclusive, but for the present we are not considering the cost of the war. It was necessary, therefore, in order to show the normal relation between the net expenses of the various groups on a peace-time basis, to exclude *in the non-civil groups all* expenditures arising from the Great War; that is, the expenses for the non-civil groups for the war years 1917 to 1919 were estimated as what they probably would have been if the war had not come, the prewar rate of change being taken into consideration.

The normal relation, on a peace-time basis, between the net expenses of the various groups can best be shown by the average calculated on the above basis for the ten years. The results are shown in Fig. 1. The net annual expenses for the three civil groups, including the legislative, executive, and judicial activities, all the research, educational and developmental work, as well as public works, amounted to $211,337,288—less than one-third of the whole. If we divide this sum by the population of the country at the middle of the 10-year period, 98,000,000, we have the average per capita cost of the civil activities of the Government. This average annual cost to the taxpayer of the civil activities of the Government amounted to approximately $2.15 per capita, divided as follows:

For Primary Governmental Functions (Group I)......	$1.08
For Research, Education and Development (Group II).	0.28
For Public Works—New Construction (Group III)....	0.79
Total for Civil Activities........................	$2.15

Since the war the expenses of the Government have increased enormously, and it seems to have been assumed by some that the civil bureaus and departments have increased their activities and expenses in the same proportion as the total has increased. Much has been said and written about the great expansion of the bureaus, and this means or, at least, includes, the civil bureaus; and the need for curbing their growth and cutting their estimates is often emphasized. Some writers, while saying little of their usefulness or the increased need of their services, say much of their inefficiency, extravagance and overdevelopment, and of the duplication of work by different bureaus or departments. These statements are usually made in general terms and without proof or particulars, but they appear to be made in good faith and apparently with the belief that bureau officers are more anxious to expand their functions and spend money than to increase the efficiency and usefulness of their respective bureaus This opinion is so seriously at variance with what one should expect that it appears worth while to examine the facts in the case.

Fig. 2 shows in more detail the cost of the separate civil activities than is shown in Fig. 1. It will be noted that the legislative, executive, and judicial group absorbed almost exactly one-half of the total for the civil groups, public works represented 36.8 per cent, while 13.2 per cent was devoted to research, educational and developmental work. Expressed in terms of the whole these percentages are:

	Per cent
Legislative, Executive, and Judicial	16.0
Research, Education, and Development	4.2
Public Works	11.7
Total for Civil Groups	31.9

The actual expenditures for all the civil activities are shown for each year in Fig. 5. The variation of the total for any year from

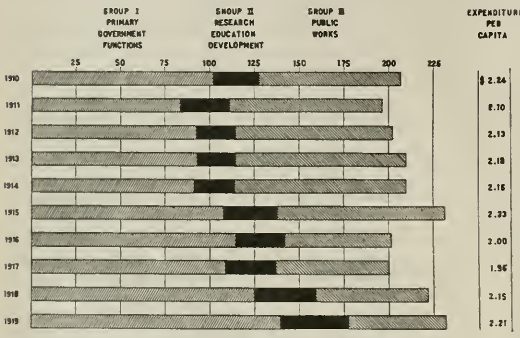

Fig. 5 Allocation of Civil Expenditures of U. S. Government from 1910 to 1919 in Millions of Dollars

the average does not exceed 10 per cent, notwithstanding the fact that general price levels for commodities have more than doubled in recent years and wages outside of the Government service have, in general, risen correspondingly. Particular attention is directed to the fact that no deductions have been made in the expenditures of these civil departments, such as the State and Treasury Departments, which necessarily had to be expanded on account of the war. The per capita net civil expenses are shown in the last column. Attention is also called to the fact that the trend of the per capita costs of the civil activities of the Government was slightly *downward* before the war, with the exception of 1915, which was largely attributable to increases in the net cost of the postal service and immigration service and to a special appropriation of $4,000,000 for eradication of the foot and mouth disease. It is proper to add that there was an appreciable increase in Groups I and II, counterbalanced by a decrease in Group III during the 10-year period.

The relationship between changing wholesale price levels, which largely represent the cost of doing business, and the per capita civil cost is graphically illustrated in Fig. 6. If the cost of the latter were reduced in proportion to the reduction in the purchasing power of the dollar in 1919 as compared with 1910, it would be found that instead of an increase in the cost of the civil government an effective reduction of nearly 50 per cent actually occurred. This largely explains the huge labor turnover in the government service and the reduced efficiency resulting therefrom, as more fully discussed later.

The sources of the revenue of the Federal Government will be of interest. It will be seen from Table 1, the data for which have been taken from the report of the Bureau of Internal Revenue, that while the principal sources of revenue are the income and excess-profits taxes, large amounts are realized from miscellaneous taxes and from customs.

The average net cost for the ten years of the civil activities, including all the research, educational and developmental activities as well as public works, was previously stated as $211,337,288. This is considerably less than the internal-revenue tax for 1920 on cigars and tobacco alone.

TABLE 1 ANALYSIS OF TOTAL U. S. TAXES FOR FISCAL YEAR 1920

Internal Revenue	Net Amount	Per Capita
Income and Excess Profits	$3,957,699,871	$37.20
Cigars and Tobacco	294,813,073	2.77
Transportation and Other Utilities	289,386,302	2.72
Autos, Candy, Furs, Jewelry, etc.	268,480,355	2.53
Beverages	197,353,439	1.86
Special Taxes on Capital Stock, etc.	105,508,052	0.99
Estate Inheritance	103,628,105	0.97
Stamps on Legal Papers, etc.	84,349,027	0.79
Admissions to Amusements, etc.	81,931,781	0.77
Insurance and Miscellaneous	24,925,468	0.23
Customs	307,253,787	2.89
Total	$5,715,329,260	$53.72

Group II The Scientific and Engineering Work of the Government

The members of the engineering profession are, however, more especially interested in the constructive activities, all included in Groups II and III. Figs. 3 and 4 have accordingly been prepared to show in detail the nature of the work and wide range of scientific and industrial research and engineering construction. Gross disbursements, receipts and net expenses are shown on these charts. While Fig. 3 is based on the *average* for the fiscal years 1910 to 1919, Fig. 4 shows the *aggregate* expenditures and earnings during the entire period, together with the relative amount for each year.

The fifteen bureaus of the Agricultural Department constitute the first half of Group II. This work is of fundamental importance not only to farmers and agricultural communities but to the entire population, for an abundant supply of food is essential to the welfare and even existence of the nation and as the urban

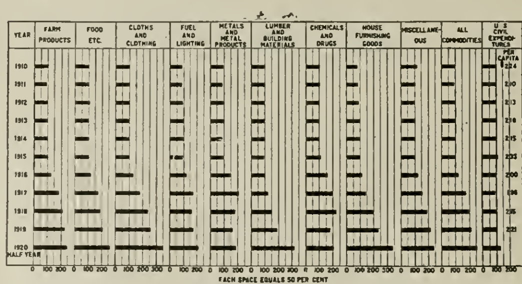

Fig. 6 Wholesale Prices for 1910 to 1920 Compared with U. S. Civil Expenditures
1913 = 100 Per Cent

population increases more rapidly than the rural, the food problem becomes more serious. The total cost of these investigations is not one-tenth of 1 per cent of the value of the agricultural products produced, and there can be no question that the value of the work done far exceeds its cost.

The Geological Survey is one of the oldest of our scientific bureaus and has done notable work of the greatest scientific and economic value. It includes, besides structural and economic geology, topographic surveys and studies of water supply and water power. The Bureau of Mines is an outgrowth of the Geological Survey, and is concerned with all the problems of mining and quarrying and the handling and treatment of their products, and also many phases of the petroleum and natural-gas industry, and the use of fuels. These materials are fundamental to the industries, and work which helps the production of fuels and such important raw materials as metals and minerals is of prime importance.

The Bureau of Education has done important and useful work, but has never been developed on a scale commensurate with the importance of its field. It is believed by many that the Bureau of Education should take a leading part in studying the science of education, and coöperate effectively with the educational institutions of the country in setting standards of education. It would not and could not dominate or control education, and there would be no danger of such a result. But it should be able to coöperate effectively and worthily, and to assist in raising educational standards where they are too low. The Federal Government is now assisting the states to the extent of a hundred million dollars

the supremely important work of education by taking a leading part in studying the problems of education?

Four bureaus of the Department of Commerce a e included in Group II. The Coast and Geodetic Survey does fundamental work upon which all other surveys are based, and also does the valuable work of charting the coasts and locating obstructions to navigation. The Bureau of Standards maintains the fundamental standards of physical measurement. It coöperates with foreign governmental institutions in maintaining international uniformity in such measurements. It provides or calibrates copies of standards for states and manufacturers so as to insure uniformity in physical measurements. It develops instruments and methods to secure the highest possible accuracy in measurement and the greatest permanence and reliability in standards. It coöperates with engineering and trade organizations in standardization work, and carries out investigations on the properties of materials to secure data for such standardization. It furnishes information to the various branches of the Federal Government, to state commissions and officers of state and municipal governments, and to the industries of the country and the general public.

Much other valuable work of an educational and developmental character is shown on the Group II chart. The average cost of all this work for the 10-year period was *28 cents per year per capita of the country's population*, certainly a very small sum in proportion to the importance of the interests represented, and also in proportion to the aggregate of the federal taxes collected.

Group III New Construction

The Panama Canal was opened to navigation in 1914. Its total cost for construction and equipment to date is $367,000,000. During the past six years its revenues have amounted to about $34,000,000 and its expenditures for operation and maintenance to $36,000,000, a net deficit of $2,000,000 for the entire period. Had it not been for the slides in 1916, which closed the canal for seven months and greatly reduced the revenue that year, there would have been a surplus of $2,000,000 for the entire period instead of a deficit. The surplus in the fiscal year 1920, amounted to more than $2,000,000, and this should increase year by year. More than $210,000,000 out of the total cost of $367,000,000 was provided out of current revenues of the Government from 1910 to 1915, and hence was included in the $2.15 per capita of civil governmental cost during these years. This is one of the engineering triumphs of the present century, and is another illustration of the successful handling of large public undertakings by the people coöperatively, that is, by the Government.

Another large undertaking of an engineering character is the river and harbor improvements, carried out by the engineers of the army but charged in this study to Public Works. During the ten years, 1910 to 1919, inclusive, more than $350,000,000 was expended in this very important work. From Hell Gate to the Golden Gate, and from Duluth to the delta of the Mississippi, this work has been carried on for many years and is of great aggregate importance.

A third important item in this group is the construction of new public buildings, and during the ten-year period in question $135,197,494 was expended in the construction of post offices, custom houses, hospitals and other Government buildings, about one hundred twenty new buildings per year being erected. The work is done by the office of the supervising architect of the Treasury Department, which for many years has handled this work. This also comes within the total of $2.15 per capita of civil governmental cost, about 79 cents of which was expended in the public-works group. In addition to the construction of new buildings the supervising architect's office has charge of the operation and maintenance of 1300 public buildings in all parts of the country.

The fourth item in this group is the construction of rural post roads, by coöperation with state highway departments. This work has been greatly expanded recently. During the ten years, 1910 to 1919, inclusive, $4,970,489 was expended in the aggregate. But the appropriation for 1920 was $99,000,000, and for 1921, $104,000,000. This is more than the annual expenditure previous to 1920 for the entire range of engineering work included in Group the country is now well understood, and there can be no doubt that the coöperation of the Federal Government will be to the advantage of the people as a whole. The building of roads is an engineering matter in which technical information and experience are of very great importance. The aid of the Federal Government not only stimulates and aids the states, which must pay at least half the cost, but tends to secure the best engineering service and to standardize road construction. It cannot fail to have a great educational influence upon engineers and road builders throughout the country, and to give the users of roads better roads and the taxpayers more for their money than if it is left to individual states. Moreover, in planning and building national highways it is very advantageous to have the Federal Government an active participant, in order to secure a better coördination of effort. As a measure of military precaution and preparedness the realization of a system of good roads on a national scale is of enormous advantage. As a help in getting food to market and supplies to farmers, it is of enormous economic value. As supplementing and in some cases supplanting railroads, such a system of highways is of great significance.

The fifth item is the Alaskan Railway, from Seward to Fairbanks. During the years 1913 to 1919, inclusive, $31,081,628 was expended on this important railway, which, when completed, will be 540 miles long. As with the Panama Canal, this is not an undertaking which private capital would care to undertake. But its ultimate success and its value in the development of Alaska can hardly be doubted.

The sixth item is the Reclamation Service, one of the most profitable and most interesting of the engineering projects of the Government. To reclaim the deserts and to create farms and homes and villages where before was waste and desolation is an inspiring undertaking; and to be able to create wealth far in excess of the cost of the work furnishes a double incentive. Since 1902 the Reclamation Service has constructed irrigation systems to supply 1,780,000 acres of land with water, and storage reservoirs sufficient to supply an additional million of acres. On this reclaimed land 40,000 families are living, and the population of the towns and villages within these projects had increased by as many more. It is estimated that the increased value of the land due to the work of the Reclamation Service is $200 per acre, or a total of more than $350,000,000. The annual value of the crops raised on these lands is estimated at $90,000,000. Most of the money expended on this work is derived from the sale of public lands and the money collected from settlers for the improvements made and the water service rendered.

The Forest Service is akin to the Reclamation Service in that it is developing the public domain. It has been included in Group II, but may be mentioned in this connection. The national forests are located in 29 states in all parts of the country, although the larger portion is in the Far West. There are 152 different forest tracts, with a total area of 156,000,000 acres. The Forest Service has the responsibility of protecting and managing these vast tracts of land; studying how to develop the land best and make its resources most useful to the public. It yields a large revenue each year from timber cut (last year 800,000,000 board feet), and affords on its grazing ranges pasturage for 15,000,000 head of sheep, cattle, horses, goats, and swine. Watching the forests for the outbreak of fire, and fighting fires when they gain headway, is one of the important duties of the Forest Service. Another duty is applying scientific forestry to the development of the forests. Still another is studying the properties of woods and methods of treating and using woods. The Forest Products Laboratory of the Forest Service has done a great deal of valuable scientific and engineering work on a wide range of subjects. In planning its work and in developing the forests the Forest Service takes a long look ahead. Obviously, no commercial company could undertake such a work. The question of early dividends is not paramount with the Government We have drawn lavishly, even recklessly in some cases, upon our natural resources, and it is well that we should be taking some thought for the future, and should be able to hand down to the next generation our public forest areas in better, rather than worse, condition than they are at present.

SURVEY OF ENGINEERING PROGRESS

A Review of Attainment in Mechanical Engineering and Related Fields

Tidal-Power Development

REPORT on tidal power, outlining scheme for the utilization of tidal power in the estuary of the Severn, which is, next to the Thames, the longest river in England, and where the power available, by reason of the large ebb and flow, is greatly in excess of all the potential sources of inland water power within the United Kingdom put together. For this reason and, prompted by the growing necessity of economizing in the consumption of the national coal resources, the Water Power Resources Committee of the British Board of Trade has undertaken an exhaustive investigation and a scheme for the utilization of such power is suggested in its third interim report published toward the end of last November.

The Committee states that the importance of the project from the national standpoint cannot be easily overrated in view of the magnitude of the power involved, and of the far-reaching character of the economic consequences which would follow the actual development of such a scheme if it could be carried out on sound economic lines.

From data presented, one particular site on the Severn, not necessarily the best, might be rendered capable of developing tidal power representing a saving of from one and a quarter to two and a half million tons of coal per year, and this without even interfering with the navigation in the estuary.

The question is, to what extent can this be actually accomplished? In the Severn estuary the tidal amplitude is large; and the configuration of the estuary is well suited to the purpose in view. The physical characteristics of the land in the vicinity are such as to facilitate the construction of a high-level storage reservoir, while the adjoining industrial district is one in which the power requirements are already large and the power supply is likely to be absorbed completely fo· industrial purposes. At the same time, however, there is no tidal-power development of any considerable magnitude in existence and no experience available to serve as a guide.

In view of this fact a sub-committee composed of Sir Philip Dawson and Prof. A. H. Gibson was appointed for the purpose of a preliminary examination of the subject. While this sub-committee has not been able to secure any definite statement of opinion from the leading manufacturers of water turbines and electric generators that would recommend the Severn scheme as a practical undertaking, its members came to the unanimous agreement that it certainly cannot be dismissed as impractical and that a further and more detailed technical inquiry into the subject of tidal power is amply justified and should be initiated without delay. It is therefore proposed to appoint a larger committee for a more careful study of the problem, and an intensive program of investigation for this committee is projected.

What appears to be one of the greatest difficulties in the way of tidal-power development is due to the intermittent character of the service which such a development can give. The report comes, therefore, to the conclusion that if an electrochemical, electrothermal or other process were devised capable of absorbing an intermittent power supply subject to such variations as are inherent in tidal-power generation, the commercial value of tidal power would be greatly increased. Otherwise, it would be necessary to provide means for providing the intermittent output into a continuous supply more or less constant throughout the working period, and such conversion can be accomplished only at the expense of overall efficiency. (Abstracted through *The Engineer*, vol. 130, no. 3390, Dec. 17, 1920, pp. 614–615, *gA*)

Tidal-Power Development, Prof. A. H. Gibson. A technica paper, the author of which together with Sir Philip Dawson constitute the sub-committee of the committee appointed by the British Board of Trade to investigate the subject of tidal-power development, in particular on the Severn River.

The author discusses the several schemes of tidal-power development proposed from time to time. All of these schemes are based on the employment of one or more tidal basins in which dams or barrages are used, either to separate the tidal basins from the sea or from each other. The power is generated by means of turbines which are arranged so as to operate either on the falling tide only or on both rising and falling tides. In accordance with the various schemes employing two basins, the turbines are placed either in the dividing wall between the basins or in the wall dividing the basins from the sea.

The author comes to the conclusion that for an estuary of the type of the Severn, the use of multiple basins is out of the question on account of the cost. The only schemes worthy of serious consideration appear to be those based on the use of a single tidal basin developing power either in the outflowing tide only or on both rising and falling tides, and with the turbines coupled to

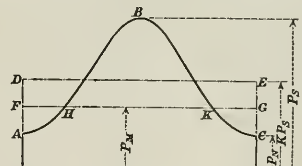

Fig. 1 Curve Representing Tidal Ranges Through one Lunar Cycle

generators which deliver directly into the distributing system when the demand permits of this, and which at other times supply the motors of a pumping station supplying water to an elevated reservoir for which a secondary system of turbines is supplied as required under a constant head.

The following will be found of general interest in connection with the design of tidal-power projects.

Mean Output during a Lunar Cycle. When the tidal range for each day during a lunar cycle is known and the working period and mean head for each day have been settled, the output in horsepower-hours per tide from the primary turbines may be determined and the curve may be plotted on a base representing the number of tides to show the output per tide, as in Fig. 1. The mean height of this curve represents the mean output of the primary turbines over the lunar cycle.

Assuming the curve representing the tidal range to be a sine curve with a mean height of H and a fluctuation $\pm h$ and assuming the working head to be proportional to the tidal range, the output per tide with the given turbine capacity will be sensibly proportional to the square of the tidal range and for any particular tide will be equal to—

$$k(H + h \sin \theta)^2$$

where k is a constant. From this is derived the mean output of he primary turbines over the whole cycle as being equal to—

$$\frac{3(P_S + P_N) + 2\sqrt{P_S P_N}}{8} \text{ hp-hr.} = KP_S \text{ hp-hr.}$$

If, for example, the tidal range at springs is twice as great as at neaps, so that $P_S = 4P_N$, the mean output will be $0.594P_S$, while if $P_S = 8P_N$, the mean output will be $0.51\ P_S$.

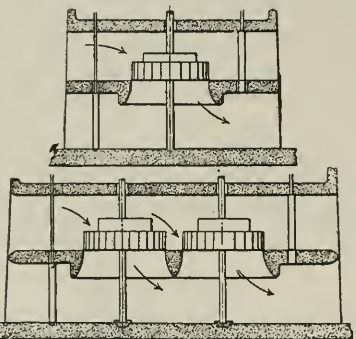
The curve *ABC* of Fig. 1 represents the output per tide in the clase where $P_S = 4P_N$, while *OD* represents the mean output per

tide over the cycle. Actually, however, a portion p of the output of the primary turbines is lost in the process in various ways. If q be the fraction of a complete tide during which the primary turbines operate and if P_M be the mean output into the distribution system from both primary and secondary turbines in horsepower hours per tide, then if p be taken as being equal to 50 per cent and if the turbines operate for 5 hr. per tide,

$$P_M = \left\{ \frac{100 - 50}{100 - 20} \right\} KP_S = 0.625\ KP_S$$

With the system of operation involving a 10-hr. working period per tide P_M would equal a value 66 per cent greater than would be obtained if all the output of primary turbines were utilized for storage.

From this the author proceeds to the consideration of the three basic schemes of tidal-power development, namely:



Figs. 2 and 3 Settings for a Dam in a Tidal-Power Development

I—Turbines operating on a falling tide only with a constant rate of fall in the basin.

II—Turbines operating on both rising and falling tides with constant rates of rise and fall in the basin.

III—Turbines operating on rising and falling tides under the natural difference of head existing at any given instant.

An analysis of the first scheme of operation on a falling tide only with a constant rate of fall in the basin shows that the range of working heads (assuming Severn conditions) is from 25 ft. to 8 ft., and the difficulty of insuring reasonable efficiencies at constant speed over this range would be great. By reducing the working head at spring tides this inequality may be reduced, and by arranging the working period so to extend beyond low tide a greater output may be obtained. By limiting the turbine capacity to that necessary to absorb the energy available at neap tides, the cost of the turbines and of the time in many cases will be reduced to 74 per cent of its original value. This can be done at a sacrifice of only 15 per cent of the continuous 24-hr. output, with economies in several other directions.

The second and third schemes are discussed in detail, the general conclusion arrived at by the author being that the first scheme, which involves operation on a falling tide only, has the disadvantage that the output is only about two-thirds of the output theoretically possible with double-way operation (Table 1). On the other hand, the output per unit of turbine capacity is sensibly the same, while it enables a much more efficient type of turbine setting to be used and the number of sluice gates to be halved. It has the further advantage where applied to a navigable river that the depth of water in the basin never falls below mean tide level or thereabouts, so that navigation above the basin is improved. The scheme is essentially more simple than any one involving double-way operation, and the balance of advantages would appear to be heavily in its favor.

Double-way operation under natural head has the disadvantage that the variation in working head is normally very great, while if the conditions be modified so as to reduce this variation the power developed falls off seriously.

General Arrangement of Turbines. In view of the large number of turbines necessary, and of the great volume of water to be handled, the only feasible arrangement, in a large installation, consists of a long dam, which may require to be curved, or to be carried diagonally across the estuary in order to provide sufficient room for the turbines and sufficient waterway for the necessary sluices. A simple type of setting which has been suggested is shown in Fig. 2, and a second type, intended to reduce the necessary length of dam and the number of sluices by installing the turbines in a double bank, is shown in Fig. 3. Owing to the fact that the modern low-speed turbine has of necessity a high velocity of flow through its runner, often amounting to as much as $0.75\sqrt{(2gh)}$, it is necessary for high efficiency to form the discharge passages with easy curves and gradually increasing sections, so as to reduce the loss of energy at discharge to a minimum, and so as to reduce the velocity of ultimate discharge to something in the neighborhood of 4 ft. per sec. For example, with a mean working head of 13 ft. (4 m.) the velocity of discharge from the runner, taking this to be only $0.5\sqrt{(2gh)}$, would be equivalent to a head of 2.5 ft., and the maximum possible overall efficiency of the turbine, assuming

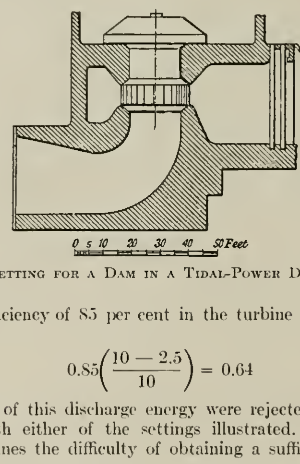


Fig. 4 Setting for a Dam in a Tidal-Power Development

hydraulic efficiency of 85 per cent in the turbine itself, would be only—

$$0.85\left(\frac{10 - 2.5}{10}\right) = 0.64$$

if the whole of this discharge energy were rejected, as would be the case with either of the settings illustrated. With double-banked turbines the difficulty of obtaining a sufficient waterway area in the face of the dam to insure even such velocities as these is almos insuperable, and would appear definitely to preclude this type of setting.

The only really efficient type is indicated in Fig. 4. Adopting

TABLE 1 COMPARATIVE RESULTS OF WORKING UNDER TIDAL-POWER DEVELOPMENT SCHEMES I, II AND III

Scheme	Method of Operation		Output, Continuous 24-Hour, assuming 50 per cent Losses in Pumping and Storage	Working Period per 25 Hours: Springs	Working Period per 25 Hours: Neaps	Working Heads: Springs Max	Working Heads: Springs Min.	Working Heads: Neaps Max.	Working Heads: Neaps Min.	Capacity (under a Head of 13 ft.) of Primary Turbines required for the Scheme
I	Falling tide only—with constant rate of fall in basin	(a)	7,680	7.4	6.6	25.0	21.0	9.8	8.0	36,700
		(b)	8,400	12.0	6.6	22.5	8.0	9.8	8.0	33,600
II	Rising and falling tides—with constant rates of rise and fall in basin:									
	All energy absorbed	(a)	13,150	13.0	12.0	11.9	10.0	7.8	6.5	116,000
	Only part of energy absorbed on a rising spring tide	(b)	11,000	13.0	12.0	11.9	10.0	7.8	6.5	68,000
III	Operation on rising and falling tides under natural head		12,400	20.4	13.6	19.0	4.0	6.0	4 0	54,000

under this head, of approximately 60 b.hp. per foot run of the dam. With smaller turbines the output per foot run of dam would be smaller, amounting to abou 50 b.hp. per foot run for turbines of 2000 b.hp. capacity.

Thus in Scheme I, seventeen turbines, each of 2000 b.hp. capacity would be required, and these wou'd require a dam at least 680 ft. long.

Owing to the relatively large variations in working head in any simple scheme, the question of the most suitable type of genera'ing machinery is one of some difficulty. Under the extreme variations of head occurring in any such scheme, the efficiency of any constant-speed turbine falls off somewhat rapidly, especially at the lower heads, although recent developments of such turbines have shown results which would have appeared impossible only a few years ago. Turbines are now available which are capable of operating under a variation of head equal to 50 per cent on each side of the mean, with efficiencies which do not fall appreciably below 70 per cent over this range, so that this method of operation is quite feasible. It is understood that one well-known firm is prepared to construct variable-speed turbines coupled to constant-speed alternators, and if this can be done without undue mechanical complication and cost, it will probably prove the best solution.

Another possibility consists in coupling the primary turbines to alternators, at a fairly low frequency, and to transmit all the power, through a comparatively short transmission line, to motor-driven centrifugal pumps coupled to synchronous motors. In order to avoid the cost and complication of transformers, the limit of voltage might be that for which the machines can be conveniently wound, i.e., about 10,000 volts. Under these conditions the speed of the primary turbines would be allowed to vary with

with provision for adjusting the number of stages in use according to the speed of the primary turbines. This method, involving the storage of all the output of the primary turbines, however, involves a relatively low overall efficiency.

The difficultites of speed variation and electrical regulation could largely be overcome by the use of direct-current generators, which would enable the turbines to be operated always at the speed corresponding to the available head, and under conditions of high hydraulic efficiency, and in view of the possibilities of the Thury scheme of high-pressure direct-current generation and transmission this method must be considered as offering a possible solution.

Another possibility consists in coupling the primary turbines directly to centrifugal pumps discharging into the storage reservoir through one or more conduits or pipe lines. The practical feasibilities of this depends on the topographical features of the site. Where the storage reservoir is not in very close proximity to the dam, and where the head is large, the cost of the necessary conduits would in general be excessive. Moreover, the difficulty of arranging the design of the dam so as to include these would be great. It is probable, indeed, that this latter factor would preclude the use of this otherwise simple method in any installation having a long dam and a large number of primary turbines, though it might offer the best solution in a small installation.

For any given scheme it is essential to give full consideration to all the possible mechanical and electrical expedients for developing the power, and to compare these from the view of simplicity, overall efficiency, first cost and cost of operation and maintenance. (*Engineering*, vol. 110, nos. 2867 and 2868, Dec. 10 and 17, 1920, pp. 778–780 and 793–795, 17 figs., *tA*)

Ignition and Cooling in Gasoline Engines—Reports of the National Advisory Committee for Aeronautics

THE Fifth and Sixth Annual Reports of the National Advisory Committee for Aeronautics covering the years 1919 and 1920 present a mine of valuable information on subjects connected with the design and construction of aeroplanes and their propelling machinery. As it would be difficult to present even the main conclusions of the work reported in about 1000 pp. of the original documents, attention will be called here only to what might be called the high spots of this important work.

The parts of particular interest to mechanical engineers, in general, are those dealing with the power plant of an aeroplane, particularly as much of the information contained in the report has immediate application to gasoline engines generally and not to aeroplane engines exclusively. The two subjects most extensively dealt with in the report are ignition and cooling in engines. In the field of ignition, again, particular attention is paid to spark plugs. Only one investigation (Report No. 58), by F. B. Silsbee, deals with characteristics of high-tension magnetos.

As regards spark plugs, Report No. 51, by F. B. Silsbee, gives a general discussion of the causes of failure of spark plugs, which are enumerated as follows: 1, Fouling with carbon deposit causing short-circuit; 2, fouling with oil deposit causing open circuit; 3, breaking of the insulator; 4, preignition; 5, conduction through the insulator; 6, electrical puncture of the insulator; 7, minor troubles such as warping and breaking of electrodes, etc.

Experience in the altitude laboratory at the Bureau of Standards and authoritative information received from France indicate that the first type of failure accounts for over 50 per cent of the trouble encountered in practice, particularly at high altitudes, and the third type for nearly 40 per cent; the second type of failure occurs quite frequently when first starting an engine, but very seldom develops after the engine is once running. The other types of failure are of relatively rare occurrence, but must be kept in mind in the design of spark plugs, since departure from the conventional designs is very liable to produce one or another of them.

As regards remedies for these troubles, the author comes to the conclusion that these are so conflicting in character that no general conclusions can be drawn and the design of a spark plug is in every case a matter of balancing opposing conditions to suit requirements in the particular engine considered.

The subject of gas leakage in spark plugs has been investigated by L. B. Loeb, L. B. Sawyer, and E. L. Fonseca.

The method used by the Bureau of Standards for determining gas leakage may be described as follows: The plugs to be tested are screwed into a pressure bomb, which is then filled with compressed air while submerged in a bath of oil heated to any desired temperature. The leakage of air through the plug is measured by the displacement of oil in an inverted bell jar placed over the plug. Standard conditions for testing the relative merits of different types of plugs are 15 kg. per sq. cm. (225 lb. per sq. in.) air pressure and 150 deg. cent. (302 deg. fahr.) temperature.

In the course of this investigation an interesting series of tests was made to ascertain the relation, if any, between leakage and pressure. No definite relation between the variables has been deduced; neither has it been possible to establish any definite relation between temperature and leakage. An effort was also made to determine whether there was on the whole any relation between the design of the plug and its gastightness. From data obtained it would appear that a molded insulator is distinctly superior to the other types in the matter of gastightness, and the good performance of gas plugs is said to be due to their being of molded construction.

The other methods of assembly have been found defective in one or another respect. As regards porcelain and mica insulators, the difference in respect to gastightness has been found to be very slight. It was found, however, that the laminated structure of the mica does not seriously decrease gastightness of the plug, and on the whole it would appear that leakage is more dependent upon workmanship than upon design, as tight and leaky plugs have been found in nearly every design submitted for test.

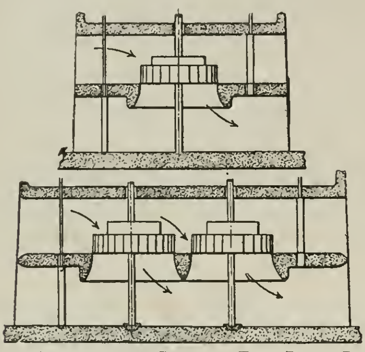
The question of the comparative temperatures in spark plugs

tide over the cycle. Actually, however, a portion p of the output of the primary turbines is lost in the process in various ways. If q be the fraction of a complete tide during which the primary turbines operate and if P_M be the mean output into the distribution system from both primary and secondary turbines in horsepower hours per tide, then if p be taken as being equal to 50 per cent and if the turbines operate for 5 hr. per tide,

$$P_M = \left\{ \frac{100 - 50}{100 - 20} \right\} KP_S = 0.625\ KP_S$$

With the system of operation involving a 10-hr. working period per tide P_M would equal a value 66 per cent greater than would be obtained if all the output of primary turbines were utilized for storage.

From this the author proceeds to the consideration of the three basic schemes of tidal-power development, namely:



Figs. 2 and 3 Settings for a Dam in a Tidal-Power Development

I—Turbines operating on a falling tide only with a constant rate of fall in the basin.

II—Turbines operating on both rising and falling tides with constant rates of rise and fall in the basin.

III—Tu bines operating on rising and falling tides under the natural difference of head existing at any given instant.

An analysis of the first scheme of operation on a falling tide only with a constant rate of fall in the basin shows that the range of working heads (assuming Severn conditions) is from 25 ft. to 8 ft., and the difficulty of insuring reasonable efficiencies at constant speed over this range would be great. By reducing the working head at spring tides this inequality may be reduced, and by arranging the working period so to extend beyond low tide a greater output may be obtained. By limiting the turbine capacity to that necessary to absorb the energy available at neap tides, the cost of the turbines and of the time in many cases will be reduced to 74 per cent of its original value. This can be done at a sacrifice of only 15 per cent of the continuous 24-hr. output, with economies in several other directions.

The second and third schemes are discussed in detail, the general conclusion arrived at by the author being that the first scheme, which involves operation on a falling tide only, has the disadvantage that the output is only about two-thirds of the output theoretically possib!e with double-way operation (Table 1). On the other hand, the output per unit of turbine capacity is sensibly the same, while it enables a much more efficient type of turbine setting to be used and the number of sluice gates to be halved. It has the further advantage where applied to a navigable river tha' the depth of water in the basin never falls below mean tide level or thereabouts, so that navigation above the basin is improved. The scheme is essentially more simple than any one involving double-way operation, and the balance of advantages would app ar to be heavily in its favor.

Double-way operation under natural head has the disadvantage that the variation in working head is normally very great, while if the conditions be modified so as to reduce this variation the power developed falls off seriously.

Genera' Arrangement of Turbines. In view of the large number of turbines necessary, and of the great volume of water to be handled, the only feasible arrangement, in a large installation, consists of a long dam, which may require to be curved, or to be carried diagonally across the estuary in order to provide sufficient room for the turbines and sufficient waterway for the necessary sluices. A simple type of setting which has been suggested is shown in Fig. 2, and a second type, intended to reduce the necessary length of dam and the number of sluices by installing the turbines in a double bank, is shown in Fig. 3. Owing to the fact that the modern low-speed turbine has of necessity a high velocity of flow through its runner, often amounting to as much as $0.75\sqrt{(2gh)}$, it is necessary for high efficiency to form the discharge passages with easy curves and gradually increasing sections, so as to reduce the loss of energy at discharge to a minimum, and so as to reduce the velocity of ultimate discharge to something in the neighborhood of 4 ft. per sec. For example, with a mean working head of 13 ft. (4 m.) the velocity of discharge from the runner, taking this to be only $0.5\sqrt{(2gh)}$, would be equivalent to a head of 2.5 ft., and the maximum possible overall efficiency of the turbine, assuming

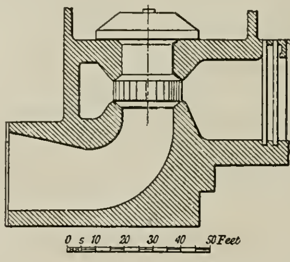


Fig. 4 Setting for a Dam in a Tidal-Power Development

hydraulic efficiency of 85 per cent in the turbine itself, would be only—

$$0.85\left(\frac{10 - 2.5}{10}\right) = 0.64$$

if the whole of this discharge energy were rejected, as would be the case with either of the settings illustrated. With double-banked turbines the difficulty of obtaining a sufficient waterway area in the face of the dam to insure even such velocities as these is almos insuperable, and would appear definitely to preclude this type of setting.

The only really efficient type is indicated in Fig. 4. Adopting

TABLE 1 COMPARATIVE RESULTS OF WORKING UNDER TIDAL-POWER DEVELOPMENT SCHEMES I, II AND III

Scheme	Method of Operation		Output, Continuous 24-Hour, assuming 50 per cent Losses in Pumping and Storage	Working Period per 25 Hours: Springs	Working Period per 25 Hours: Neaps	Working Heads, Springs: Max	Working Heads, Springs: Min.	Working Heads, Neaps: Max.	Working Heads, Neaps: Min.	Capacity (under a Head of 13 ft.) of Primary Turbines required for the Scheme
I	Falling tide only—with constant rate of fall in basin	(a)	7,680	7.4	6.6	25.0	21.0	9.8	8.0	36,700
		(b)	8,400	12.0	6.6	22.5	8.0	9.8	8.0	33,600
II	Rising and falling tides—with constant rates of rise and fall in basin:									
	All energy absorbed	(a)	13,150	13.0	12.0	11.9	10.0	7.8	6.5	116,000
	Only part of energy absorbed on a rising spring tide	(b)	11,000	13.0	12.0	11.9	10.0	7.8	6.5	68,000
III	Operation on rising and falling tides under natural head		12,400	20.4	13.6	19.0	4.0	6.0	4 0	54,000

would be required, and these wou'd require a dam at least 680 ft. long.

Owing to the relatively large variations in working head in any simple scheme, the question of the most suitable type of genera'ing machinery is one of some difficulty. Under the extreme variations of head occurring in any such scheme, the efficiency of any constant-speed turbine falls off somewhat rapidly, especially at the lower heads, although recent developments of such turbines have shown results which would have appeared impossible only a few years ago. Turbines are now available which are capable of operating under a variation of head equal to 50 per cent on each side of the mean, with efficiencies which do not fall appreciably below 70 per cent over this range, so that this method of operation is quite feasible. It is understood that one well-known firm is prepared to construct variable-speed turbines coupled to constant-speed alternators, and if this can be done without undue mechanical complication and cost, it will probably prove the best solution.

Another possibility consists in coupling the primary turbines to alternators, at a fairly low frequency, and to transmit all the power, through a comparatively short transmission line, to motor-driven centrifugal pumps coupled to synchronous motors. In order to avoid the cost and complication of transformers, the limit of voltage might be that for which the machines can be conveniently wound, i.e., about 10,000 volts. Under these conditions the speed of the primary turbines would be allowed to vary with largely be overcome by the use of direct-current generators, which would enable the turbines to be operated always at the speed corresponding to the available head, and under conditions of high hydraulic efficiency, and in view of the possibilities of the Thury scheme of high-pressure direct-current generation and transmission this method must be considered as offering a possible solution.

Another possibility consists in coupling the primary turbines directly to centrifugal pumps discharging into the storage reservoir through one or more conduits or pipe lines. The practical feasibilities of this depends on the topographical features of the site. Where the storage reservoir is not in very c'ose proximity to the dam, and where the head is large, the cost of the necessary conduits would in general be excessive. Moreover, the difficulty of arranging the design of the dam so as to include these would be great. It is probable, indeed, that this latter factor would preclude the use of this otherwise simple method in any installation having a long dam and a large number of primary turbines, though it might offer the best solution in a small installation.

For any given scheme it is essential to give full consideration to all the possible mechanical and electrical expedients for developing the power, and to compare these from the view of simplicity, overall efficiency, first cost and cost of operation and maintenance. (*Engineering*, vol. 110, nos. 2867 and 2868, Dec. 10 and 17, 1920, pp. 778–780 and 793–795, 17 figs., *tA*)

Ignition and Cooling in Gasoline Engines—Reports of the National Advisory Committee for Aeronautics

THE Fifth and Sixth Annual Reports of the National Advisory Committee for Aeronautics covering the years 1919 and 1920 present a mine of valuable information on subjects connected with the design and construction of aeroplanes and their propelling machinery. As it would be difficult to present even the main conclusions of the work reported in about 1000 pp. of the original documents, attention will be called here only to what might be called the high spots of this important work.

The parts of particular interest to mechanical engineers, in general, are those dealing with the power plant of an aeroplane, particularly as much of the information contained in the report has immediate application to gasoline engines generally and not to aeroplane engines exclusively. The two subjects most extensively dealt with in the report are ignition and cooling in engines. In the field of ignition, again, particular attention is paid to spark plugs. Only one investigation (Report No. 58), by F. B. Silsbee, deals with characteristics of high-tension magnetos.

As regards spark plugs, Report No. 51, by F. B. Silsbee, gives a general discussion of the causes of failure of spark plugs, which are enumerated as follows: 1, Fouling with carbon deposit causing short-circuit; 2, fouling with oil deposit causing open circuit; 3, breaking of the insulator; 4, preignition; 5, conduction through the insulator; 6, electrical puncture of the insulator; 7, minor troubles such as warping and breaking of electrodes, etc.

Experience in the altitude laboratory at the Bureau of Standards and authoritative information received from France indicate that the first type of failure accounts for over 50 per cent of the trouble encountered in practice, particularly at high altitudes, and the third type for nearly 40 per cent; the second type of failure occurs quite frequently when first starting an engine, but very seldom develops after the engine is once running. The other types of failure are of relatively rare occurrence, but must be kept in mind in the design of spark plugs, since departure from the conventional designs is very liable to produce one or another of them.

As regards remedies for these troubles, the author comes to the conclusion that these are so conflicting in character that no general conclusions can be drawn and the design of a spark plug is in every case a matter of balancing opposing conditions to suit requirements in the particular engine considered.

The subject of gas leakage in spark plugs has been investigated by L. B. Loeb, L. B. Sawyer, and E. L. Fonseca.

The method used by the Bureau of Standards for determining gas leakage may be described as follows: The plugs to be tested are screwed into a pressure bomb, which is then filled with compressed air while submerged in a bath of oil heated to any desired temperature. The leakage of air through the plug is measured by the displacement of oil in an inverted bell jar placed over the plug. Standard conditions for testing the relative merits of different types of plugs are 15 kg. per sq. cm. (225 lb. per sq. in.) air pressure and 150 deg. cent. (302 deg. fahr.) temperature.

In the course of this investigation an interesting series of tests was made to ascertain the relation, if any, between leakage and pressure. No definite relation between the variables has been deduced; neither has it been possible to establish any definite relation between temperature and leakage. An effort was also made to determine whether there was on the whole any relation between the design of the plug and its gastightness. From data obtained it would appear that a molded insulator is distinctly superior to the other types in the matter of gastightness, and the good performance of gas plugs is said to be due to their being of molded construction.

The other methods of assembly have been found defective in one or another respect. As regards porcelain and mica insulators, the difference in respect to gastightness has been found to be very slight. It was found, however, that the laminated structure of the mica does not seriously decrease gastightness of the plug, and on the whole it would appear that leakage is more dependent upon workmanship than upon design, as tight and leaky plugs have been found in nearly every design submitted for test.

The question of the comparative temperatures in spark plugs

having steel and brass shells was investigated by C. S. Cragoe (Report No. 52) to determine whether brass is superior to steel for that purpose, because of its greater heat conductivity. The tests were made on an aeronautical motor and also on a truck motor. In the latter case, however, a special cylinder head was used which gave a maximum compression of about 115 lb. per sq. in., which brought the truck motor practically into the aeronautical-motor class as far as temperature conditions were concerned.

The results were somewhat unexpected. The temperatures of the brass shells were found to be considerably higher than the steel in each case. The temperatures in the center of the porcelain were also higher in the case of brass shells. This is explained by the following: The heat received from the hot gases in the cylinder at the inner end of the brass plug is more readily conducted longitudinally to the upper part of the shell, which is thus maintained at a relatively higher temperature in spite of the loss of heat from the upper portions of the shell and insulator by radiation and convection. Since the contact between the porcelain and the plug in the engines tested was above the plane of the engine water jacket, the porcelain was less effectively cooled in the case of the brass plug where the upper part of the metal is hotter, and consequently shows a higher temperature throughout its length.

In this instance the tests can hardly be considered as conclusive, as apparently the design of the engine was such that the good features were carried out on an engine where the spark plug sits in a water-cooled boss, as is the practice in a good many tractor engines.

One of the most important parts of the spark plug, and also the one that is particularly apt to give trouble, is the insulator. Commercially, three kinds of insulators are known: mica; the various insulators produced from talc or soapstone, known under various trade names such as lava, steatite, etc.; and ceramic insulators, generally, though not always correctly, referred to as porcelains. Of these the third class is by far the most extensively used, especially for engines other than aeronautical. The properties and preparation of ceramic insulators for spark plugs constitute one of the most interesting reports published by the National Advisory Committee in relation to the subject of ignition.

The first problem was to develop a method of measuring resistances of insulators at high temperatures, a subject of great importance as the insulator of a spark plug has to withstand the high voltages applied to it mainly when it is heated to quite a considerable extent.

A method has been developed by the Bureau of Standards in which alternating current is used (volt-ammeter method) and tests have shown that successful measurements on a single specimen give results repeating to a few per cent. This method, however, gives results for the material in the unpolarized state, leaving largely open the very wide field of investigation concerning the phenomenon of polarization in spark-plug porcelains. The term polarization, it may be stated, has been applied to a phenomenon the fundamental manifestation of which is that if a constant direct-current voltage be applied to a specimen the resulting current will decrease at first rapidly and then more gradually. If the applied direct-current voltage be then suddenly reversed the initial current in the new direction is found to be approximately equal in magnitude to the original current and much greater than the value immediately preceding the reversal. This implies a counter-electromotive force and is analogous to certain phenomena observed when polarization is present.

The measurements made of electrical resistance of various insulating materials at high temperatures (R. K. Honaman and E. L. Fonseca) have shown that quartz is by far the best of the materials tested as far as resistance at high temperature is concerned, although several of the laboratory porcelain bodies approach this fairly closely. The mica plugs show fairly high resistivity, but it should be noted also that this material loses its water of crystallization at temperatures approaching 1000 deg. cent. and becomes very soft and friable. The steatite and Rajah porcelains from Germany are not notably high in resistivity. The French porcelains, on the whole, have been found to be not as good as the more modern American bodies.

The average commercial porcelain was found not capable of fulfilling the conditions required for spark-plug service nor for any other conditions where high-tension currents are employed and the temperature is considerably above atmospheric conditions. Because of this, an extensive investigation was undertaken (report by A. V. Bleininger), as a result of which porcelains possessing usually high qualities were developed at the Pittsburgh laboratory of the Bureau of Standards. One of the features of one of the porcelains developed was the replacement of the usual magnesia flux by beryllium oxide, which, among other things, is of interest as giving a lower thermal expansion of the porcelain than is the case in feldspathic porcelains. Attempts were also made to replace quartz, for which purpose a number of substances were tried. It was found that such materials as highly calcined kaolin, alumina, zircon or sillimanite, either natural or synthetic, are suitable, the question of selection of any one of these materials being determined by its price or available supply.

Among other things the report gives complete formulas for several new porcelains.

The subject of cements for spark-plug electrodes is covered in a report by H. F. Staley. It was found that cements in spark plugs are a prolific source of trouble. In the first place, they are apt to eat away the nickel electrode wire, or if they hold the wire firmly then they are apt to crack the porcelain due to the difference in the coefficients of thermal expansion of the wire and porcelain.

It would appear, however, that while a cement composed of silicate of soda and raw kaolin was developed that would not destroy the nickel wire, the best construction of a spark plug is the one where no cement is used at all, but instead a mechanical seal is provided at the top of the porcelain to make the plug gastight.

All the foregoing reports deal with the subject of spark-plug construction. Next comes a series of reports referring to the performance of spark plugs, starting with the report by L. B. Loeb and F. B. Silsbee on the effect of temperature and pressure on the spark-plug voltage. J. J. Thomson propounded a theory according to which the sparking potential depends solely on the density of the gas between the electrodes, that is, on the total number of molecules between the electrodes. The Bureau of Standards undertook to investigate whether this law held for pressures and temperatures which might occur in the cylinders of a high-compression engine of the aeroplane type just before the ignition of the charge. In aeroplane engines the maximum compression pressures under normal conditions range from 90 to 130 lb. per sq. in., with temperatures up to 300 deg. cent.

These experiments confirm the relation that the breakdown voltage of a spark gap depends only upon the density of the gas and varies with pressure and temperature only as they affect the density. This relation is found to be valid up to 800 deg. cent. and 8 atmospheres pressure. Both the pressure and temperature of the charge in a gasoline engine increase very greatly during the compression stroke, but the sparking voltage can be computed from the linear relations shown in a diagram accompanying the report (plot 5) without a knowledge of these variables separately, since the density is determined solely by the original density and the compression ratio. For small changes in density, as between engines of different compression ratios, the assumption that the voltage is proportional to the density may be made.

With the sudden discharge from an ignition coil or magneto a disruptive spark is produced even at temperatures where a 60-cycle voltage would produce a brush discharge.

The voltage required for a spark plug set at 0.5 mm. (0.020 in.) in an aviation engine of moderate compression is of the order of magnitude of 6000 volts.

It is by no means certain as yet what governs the ability of a spark to fire a mixture in the cylinder of an internal-combustion engine (incendivity of the spark), but it is without any doubt of considerable interest to know the heat energy of various ignition sparks. The Bureau of Standards has developed a method for measuring this energy and carried out a number of such measurements.

The ordinary spark plug is subject to a good many ills, among them fouling with carbon and oil which are deposited on the surface of the insulation and form a conducting path sufficient to prevent sparks from jumping across the air gap. One of the methods suggested as a relief in such a case was the use of a subsidiary gap, usually in series with the main air gap.

Several such devices have been tested by the Bureau of Stand-

in the case of fouling.

Another subject to which a good deal of attention has been paid is that of radiators for aeroplane engines, which is, in a way, of a somewhat passing interest in view of the fact that the general tendency in the development of aircraft engines is toward the entire elimination of indirect cooling.

An extensive report by H. C. Dickinson, W. S. James and W. B. Brown presents a general discussion of test methods for radiators which is of interest also in that it presents a careful analysis of the main factors affecting radiator performance.

The report on head resistance due to radiators is of particular interest to aeronautical engineers. So, in a way, is the report on the effect of altitude on radiator performance. On the other hand, the reports covering results of tests on radiators for aircraft engines give a good deal of information which may be of considerable value also to makers of motorcar radiators.

In these tests it was found that:

1 Heat transfer is a function of mass flow of air, independent of density.

amount of indirect cooling surface the heat transfer increases less rapidly than mass flow at high air speeds.

3 Heat transfer is proportional to the temperature difference mentioned above.

4 Heat transfer is not greatly affected by the rate of water flow provided the rate is above 2 gal. per min. per in. of core depth per ft. width of core. It should be noted, however, that this is true only when the mean water temperature is regarded as constant.

5 Heat transfer from direct cooling surface is not appreciably affected by the composition of the metal. When fins and other indirect cooling surface are used the thermal conductivity of the metal is important.

6 Heat transfer is somewhat increased, but at the expense of a large increase in head resistance by spirals or other forms of passages which increase the turbulence of the air stream. Heat transfer is greater for smooth than for rough tube walls, for, if the surface is rough, it will be covered with a layer of more or less stagnant fluid.

Electric Melting Furnaces

A HISTORY of the commercial development of the electric melting furnace, and descriptions of the principal types of electric furnaces which are now obtainable on the market for various industrial purposes.

In 1877 Siemens succeeded in melting steel by the use of the electric arc. He devised two types of furnaces: An arc-radiation furnace in which the steel was melted by radiation from an arc between two electrodes located horizontally above the metal; and an arc-resistance furnace in which the steel itself was made one of the electrodes of the arc.

The arc-radiation furnace was subsequently developed by Captain Stassano of the Italian Army, who employed three electrodes coming together in triangular formation above the bath and used a three-phase arc. From forty to fifty furnaces of the Stassano type are at present in operation throughout the world.

There are other furnaces of a somewhat similar character, heated by radiation from the arc. Sometimes the arc is changed a little in shape. Such a one is the Rennerfelt furnace, which is essentially of the same general type, though differing in details. It consists of one vertical and two horizontal electrodes, which project the arc like a blowpipe on the surface of the metal.

There are still other types of the arc furnace. There is the rocking arc furnace, in which the electrodes pass through the sides of the furnace, but the metal is rocked so that it is uniformly heated, thus combating unevenness of temperature caused by intense heating near to the arc. This particular modification of the arc-radiation furnace has been found very useful in the melting of alloys containing volatile metals, such as, particularly, brass.

The arc-resistance furnace was commercialized by Girod, a Swiss electrical engineer. He constructed a saucer-shaped, steel-melting hearth and put through a hole in the bottom of it a soft low-carbon steel rod. The electrode passing through the hearth was 18 in. long; in running it melted 6 in. and left 12 in. solid. This automatically sealed it, and the current was taken away from the projecting end outside, which was water-cooled. The Bethlehem Steel Co. runs a 10-ton Girod furnace at Bethlehem.

Further progress was made by embedding the electrode in the bottom of the hearth. A typical development on this principle is the Heroult arc furnace, in which two electrodes are used. The current passes from one electrode through the slag to the metal, through the metal, and thence back to the other electrode. There are therefore two arcs in series. Nearly two hundred and fifty Heroult furnaces are operated in the United States.

The resistance furnace is a type of furnace which does not use the arc. In it the metal is heated by the resistance of a solid or liquid material. The resistance-radiation furnace is one where the metal is heated by radiation from the resistor, the latter being heated by the direct passage of the current. Another form of resistance furnace operates on what is termed the "pinch effect," that is, the force which, when a current of high density passes through a properly proportioned liquid resistor, causes the liquid metal to be ejected from the center and the cooler metal to flow in from the periphery. Liquid metal in small channels communicating with a larger bath of metal, is heated through its own resistance. This type of furnace has received many modifications, among which is the use of current generated in the tubes by induction, so doing away with electrodes.

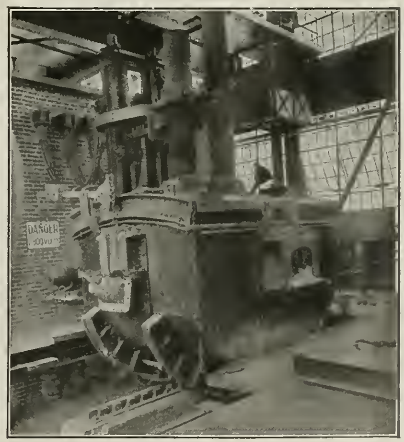

Fig. 1 Greaves-Etchells Three-Ton Electric Furnace

The Greaves-Etchells furnace is of the arc-resistance type. The transformers are connected delta on the primary side and Y on the secondary. One of the legs of the transformer is applied directly to the bottom of the furnace by means of copper busbars and a copper plate, which conducts the current through a bottom composed principally of magnesite and dolomite, in such a way that there is a graded resistance, beginning with a low resistance and ending high. The other two legs of the transformer are connected to movable electrodes, which extend down through the roof. Regulation is then maintained by the usual types of furnace regulators. Two voltages are used, the higher voltage for melting down and the lower for refining. Fig. 1 shows a rocking Greaves-Etchells three-ton electric furnace.

By a careful analysis of the conditions described above, it will be noted that the combination of a resistive bottom and the delta-Y connection of transformers is one which prevents serious overload-

ing of one phase, at the same time doing away with a specially high reactance, which is necessary on other makes of furnaces.

Metallurgically, a furnace which uses the bottom as a resistor, and therefore as a heat producer, is superior to one which generates all the heat above the bath. This is especially true of the production of alloy steel, where materials are used which have a higher specific gravity and also higher melting point than the steel itself. Rabbling becomes unnecessary in the Greaves-Etchells furnace, and the roofs last longer, since they are not punished so severely.

The shape of the lining of the electric furnace of the arc type affects its performance very materially, and if not correct may produce cold spots or hot spots in the metal.

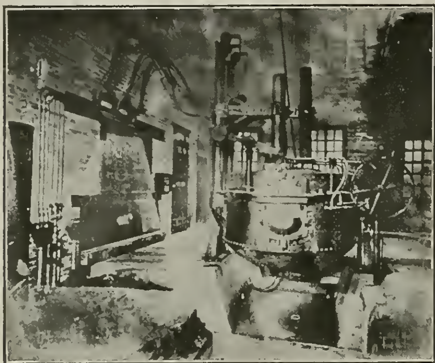

Fig. 2 One and One-Half-Ton Moore Electric Steel Furnace

For a detailed discussion of this subject, reference is made to the original article by F. W. Brooke.

In the Moore rapid "Lectromelt" arc-resistance furnace the tilting mechanism is placed above the floor and the tilting motor is mounted on a bracket to the side of the furnace where it is accessible and out of harm's way from molten steel slag and dirt. There is no mechanism in the furnace pit. The conducting arms of this furnace are also the electrode-supporting arms, a fact which permits placing the insulation between the furnace shell and the arms back at the supporting columns where it is not subject to the rapid deterioration from the heat above the furnace. The inverted dome-shaped bottom of the furnace prevents any possibility of floating the furnace bottom through the expansion of the shell, as the bottom refractories are arched in place. This furnace is designed for the rapid casting of steel, the usual time of melt-down being from one-half to three-quarters of an hour. A $1\frac{1}{2}$ ton Moore electric steel furnace is represented in Fig. 2.

An illustration of a Weeks rotating brass furnace is given in Fig. 3. In this type of furnace the metal is melted by the open single-phase arc produced by horizontal electrodes passing through the center axis of the drum. It is necessary in using an electric arc for melting brass to keep the metal thoroughly mixed in order to prevent the zinc content from boiling out, since zinc volatilizes at a lower temperature than the melting point of copper. This has been accomplished by rotating the drum about the electrodes which constantly mixes the superheated surface with the colder metal at the bottom of the bath, thus keeping the bath at a uniform temperature and the zinc so well mixed with the copper that volatilization is a minimum. The Weeks furnace operates single-phase and has for the $\frac{1}{2}$-ton size a kilowatt rating of 200 and for the one-ton size 300 kw. The power factor averages around 80 per cent.

An interesting induction furnace of the vertical ring type is the Ajax-Wyatt electric furnace. The construction of this furnace will be readily understood by noticing the sectional views of Fig. 4. In the resistor rapid circulation is obtained as a result of the combined forces exerted therein, namely "motor effect," "pinch effect," and "thermal effect." Each of these forces tends to force the metal upward. The strongest force exerted is that due to "motor" effect which is applied in greatest degree of force at the angle, which is so placed that it is at the extreme bottom of the furnace. The heating and the stirring is all applied from the bottom. No mechanical contrivance is necessary to produce circulation, or mixing. The heat losses are merely those due to radiation, and the small transformer losses. The Ajax-Wyatt furnace has thus far been developed only for melting the copper-zinc alloys. It is possible to handle the full commercial range of such alloys as is used in rolling-mill practice. Development work is progressing in adapting the furnace to other uses, and it is expected that it will shortly be possible to handle all the non-ferrous alloys in this furnace, and possibly some of the ferrous metals. (Symposium in *Journal of the American Institute of Electrical Engineers*, vol. 39, no. 12, Dec. 1920, pp. 1034–1043, 16 figs.)

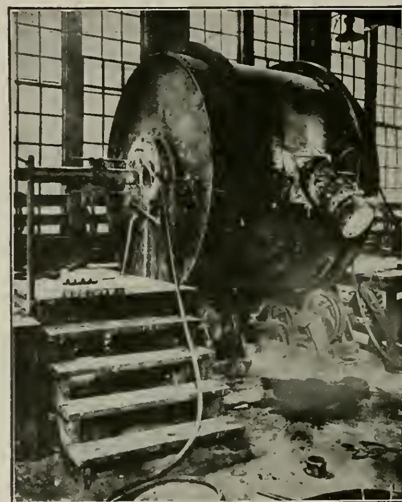

Fig. 3 Weeks Electric Rotating Furnace

A simple type of arc-radiation furnace which can be operated directly on a 220-volt motor circuit, without transformers, has been designed by Frederick von Schlegell, of the Industrial Electric Furnace Co., Chicago. The arcs are drawn, sustained and regulated by a balance system automatically giving stability. The heat element is suspended through the roof, and consists of an

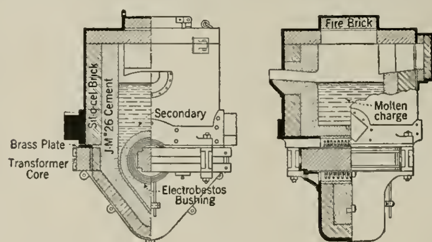

Fig. 4 Sectional Views of Ajax-Wyatt Electric Furnace

electric arc torch, which diffuses a large, intensely hot flame. The shell is cylindrical and of extra heavy steel plate, and is supported on heavy rocker trunnions which allow it to lock after pouring. Tilting is by hand and all mechanical tilting equipment has been eliminated. The furnace is built for single-phase, three-phase or direct current. With single-phase or direct current, two electrodes are used and with three-phase three electrodes. They are held in place by a refractory sleeve so mounted that the sleeve and electrodes can be raised or lowered or swung aside to permit charging through the top opening of the furnace. This does away with side doors and prevents loss of heat. The furnace is lined with an insulating coat next to the shell and a ganister lining mixed with a small percentage of fireclay, and a pine-tar product is ram-

Steel Rails from Sink-Head and Ordinary Rail Ingots. The object of this investigation was to determine the relation of ingot practice to the properties of rails from such ingots, and in particular to determine the amount of total discard necessary to obtain rails free from piping and segregation above 12 per cent, which have been rolled from steel made in accordance with varying melting, casting and ingot practices.

To that end 35 ingots, made by the converter process at Hadfield's, Sheffield, England, and cast by the sink-head process with large end uppermost, were shipped to Sparrows Point, Md., and rolled into rails; these were compared with 15 rail ingots made in the ordinary manner with the small end uppermost. Each sink-head ingot, of about 5300 lb. weight, and, deoxidized with aluminum in the mold, represented a separate heat of converter steel, and all the heats and ingots were made in the same manner. The composition and properties of these ingots were of remarkable uniformity. The comparison ingots, of 7300 lb. each, were from three separate open-hearth heats, an additional variation being made in the casting and open-hearth practice for each. Five ingots were selected from each of these three heats. Thus, in reality, comparison was made of four different kinds of steel of very nearly the same composition and physical properties, and of two types of ingot form.

The comparison was made by rolling most of the ingots into rails and taking test specimens at each rail cut, as well as from a considerable portion of the upper part, in 5-ft. steps, of the rail bar from each ingot. In this way there was obtained a detailed physical, chemical and metallographic survey of each ingot, and it was possible to delimit exactly the regions of sound and homogeneous from those of unsound and segregated steel. Two complete sink-head ingots were cut longitudinally and examined, as also were representative blooms from both sink-head and ordinary ingots.

The results obtained indicate a decided superiority of the sink-head ingots over the comparison ingots as made of three grades of steel (Tables 17 and 18), although the sink-head ingots suffered from the disadvantage of having gone cold before rolling. The Hadfield type of ingot required discard of only 18.4 per cent on the average (13 per cent top discard to eliminate piping and segregation above 12 per cent), while the average ingot of the ordinary type for rails required a total discard of 43.9 per cent (26 per cent top discard), with great variations dependent upon the furnace and ingot practices.

The comparison ingots from heat M1–M5, made of non-deoxidized rising steel chilled on top of ingot by cast-iron caps, required excessive discard to eliminate positive segregation at the top and negative segregation at the bottom of the ingot, the latter often accompanied by dangerous enclosed pipes.

The second heat (M6–M10), made of rising steel deoxidized with aluminum in the molds, the ingot tops of which were cooled with water, required the least total discard of the three heats. It was more subject to piping and less to segregation than the first heat of ingots made in the usual manner.

The third heat (M11–M15), made of quiet or "killed" steel, was not chilled on top with water or caps and was deoxidized with aluminum in the molds. The ingots of this heat required an intermediate amount of total discard when compared to the first and second heats; this heat was the only one for which a greater top discard was required to eliminate piping than to eliminate segregation above 12 per cent. One of the ingots of this third heat contained a small pipe at the bottom, and all the rails from the middle and bottom of the ingots showed high negative segregation.

The distribution of physical properties throughout the length cast, and of the ingot practice.

It has been established in the foregoing that after removal of the top discard of 13 per cent the Hadfield type of sink-head ingot is free from piping and undue segregation. The ordinary type of ingot, cast small end up without sink head, as is usual for rail ingots, requires an average top discard of 26 per cent, and the remainder of the ingot is liable to contain enclosed piping and excessive segregation. Defective rails, from the middle and bottom portion of the ingot, are not certainly detected by means of existing rail specifications, and as a result of this uncertainty rails containing pipes or excessive segregation may get into service with disastrous results.

The surface condition of the rails from the sink-head ingots was not so good as for the ordinary ingots, but this is not considered an essential characteristic of rails from such ingots.

The markedly differing characteristics of the three heats of comparison ingots leads one to raise the question whether or no it might be advisable to specify, at least in some degree, the methods of steel manufacture or of ingot practice for rails and similar products on which the safety of the traveling public depends.

While it is not claimed that the use of the sink-head process for the manufacture of ingots will solve all rail problems, it is maintained that its adoption would be a step in the right direction in view of the present heavy casualties and property losses on American railroads. The necessary changes in mill operations, it is believed, could be made without too great difficulties. (Abstract of *Technologic Paper of the Bureau of Standards* No. 178, by George K. Burgess, *c*)

The Electric Arc-Welding of Steel: The Properties of Arc-Fused Metal. A fusion weld is fundamentally different from all other types in that the metal of the weld is essentially a casting. The arc-fusion weld has characteristics which are peculiar to it alone. A knowledge of the mechanical properties of the arc-fused metal which is added during the process of welding is fundamental in the study of arc welding. The mechanical properties as revealed by stressing in tension were determined upon specimens (0.505 in. diameter, 2 in. gage length) cut from blocks of arc-fused metal prepared under conditions similar to those met in welding. Additional specimens were also prepared by expert welders outside of the Bureau and submitted for comparison with those prepared by the Bureau.

Two types of electrodes, a "pure" iron and a low-carbon steel, were used. During fusion the composition changes considerably as the carbon and other elements are eliminated and the two types become very much alike in that respect. In each case a considerable percentage of nitrogen is taken up.

The mechanical properties of the arc-fused metal as measured by the tension test are essentially those of an inferior casting. The most striking feature is the low ductility of the metal. All of the specimens examined (about 70) showed evidence of unsoundness in their structure—tiny enclosed cavities, oxide inclusions, and lack of intimate union. These appear to be a necessary consequence of the method of fusion as now practiced. They determine almost entirely the mechanical properties of metal. The observed elongation of specimens under tension is due to the combined effect of the numerous unsound spots rather than to the ductility of the metal.

The material is, however, inherently rather ductile, as may be shown by the changes produced in its microstructure by cold-bending.

A characteristic feature of the microstructure of the arc-fused metal is the pressure of numerous microscopic plates within the ferrite grains. These persist in the metal upon prolonged heating, for example, 6 hr. at 1000 deg. cent. in vacuo were not sufficient to remove them. The various lines of evidence available indicate that they are related to the nitrogen content of the metal.

The microscopic examination indicates that there is but little, if any, relation between these so-called "nitride plates" and the path of rupture produced by tensional stresses. The effect of the grosser imperfections of the metal is so much greater than

any possible effect of those plates in determining the mechanical properties that the conclusion appears to be warranted that this feature of the structure is a matter of relatively minor importance in ordinary arc welds.

Judged from the properties of the metal after fusion, neither type of electrode used appears to have a marked advantage over the other. The use of slight protective coatings on the electrodes does not appear to affect the mechanical properties of the arc-fused metal materially in any way. The specimens were prepared in a manner quite different from that used ordinarily in electric arc welding and so do not justify specific recommendations concerning methods of practice in welding. (Abstract of *Technologic Paper of the Bureau of Standards* No. 179, by Henry S. Rawdon, Edward C. Groesbeck, and Louis Jordan, *e*)

INTERNAL-COMBUSTION ENGINES

Possible Fuel Savings in Automotive Engines, H. C. Dickinson and S. W. Sparrow. Report of tests carried out at the Bureau of Standards. The apparatus employed made it possible to see the acceleration of the engine by means of an acceleration disk mounted on the dynamometer shaft. This was of steel, 33 in. in diameter and $^1/_2$ in. thick. Its inertia added to that of the dynamometer was about equal to that of a 3500-lb. car on direct drive with a gear ratio of 5 to 1 and 32-in. wheels.

Among other things, the tests covered the influence of jacket-water temperature on fuel economy. Two series of tests were made; in the one the temperature of the water entering the jacket was maintained at 162 deg. fahr., and in the second at 72 deg. fahr. Runs were made at full load and at 0.8, 0.6, 0.4, and 0.2

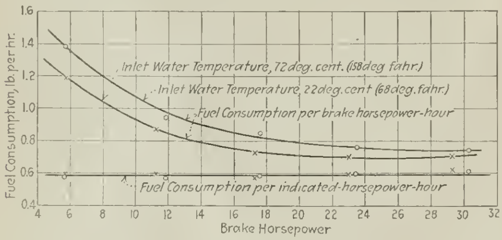

Fig. 1 Curves Showing the Relation Between Fuel Consumption and Jacket-Water Temperature

of full load, with five carburetor adjustments at each throttle setting. From these results the minimum fuel consumption for each setting has been selected and plotted in Fig. 1. From this it appears that the fuel consumption per unit power based on brake horsepower is considerably higher with the cold jacket water.

It may be mentioned, in this connection, that tests made several years ago by J. B. Replogle showed that a very considerable economy in fuel consumption is obtained when the temperature of water is carried to a still higher point than was used by the Bureau of Standards in its test, namely, at the boiling point.

Other tests cover the influence of intake-manifold heating on acceleration and on the maximum horsepower of the engine, it having been found that heat supplied to the charge increases the maximum power of the engine. (Paper presented at the meeting of the American Petroleum Institute, Nov. 17, 1920; abstracted through *Journal of the Society of Automotive Engineers*, vol. 8, no. 1, January 1921, pp. 3–9, 14 figs., *cg*)

MACHINE TOOLS

Improving Efficiency of Twist Drills by Enlarging the Helix Angle

Helix Angle of Twist Drills, Bruce W. Benedict, Mem.Am. Soc.M.E. The operation of the twist drill resembles the action of tearing. The more the action of the tool resembles cutting as opposed to tearing, the more effective the tool is. This condition is secured by increasing the keenness of the cutting edge to a degree that does not result in a sacrifice of its endurance.

As regards twist drills, the author doubts if their manufacturers have attempted to utilize fully the principle of keenness in the cutting edge to the extent permitted by the use of high-speed steel, and with one exception they are producing high-speed twist drills of exactly or of approximately the same cutting angle as was established by them in the days of the carbon-steel drill. In fact, with one exception, milled drills of both carbon and high-speed steel of prominent makers have identical helix angles. (The helix angle as here used is the angle between the cutting face at the periphery of the drill and the axis of the drill and is a measure by which keenness of the cutting edge or the degree of the cutting angle is determined.)

With the exception of one company which markets a special drill having an angle of 32 deg. at the point, the helix angles of milled drills vary between 20 and 26 deg., the majority having angles of either 22 or 26 deg. In many of these drills the helix angle is decreased gradually toward the shank, a total of two or three degrees, so that cutting angles become increasingly blunt as the drills wear.

To determine the most efficient helix angle for use on high-speed

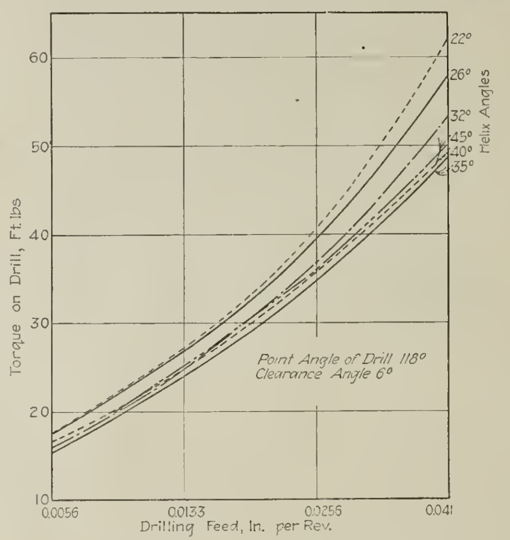

Fig. 2 Power Required to Drive 1-In. Drills of Various Helix Angles at Various Feeds in Cast Iron

milled twist drills, an investigation was carried out with milled drills having helix angles ranging from 10 to 45 deg., 1-in. drills being used throughout.

Data are given in the original article showing the effect of changes in the helix angle on the power required to rotate the drill against the work and remove the chip (Fig. 2), which show a very peculiar variation.

In connection with these curves, the curves of Fig. 3 showing the total end thrust on drills of various helix angles is of considerable interest. Here the thrust decreases progressively as the helix angle increases, reaching the minimum for drills of 45 deg. angle. For certain mechanical reasons, however, it is inadvisable to consider the use of helix angles above 45 deg.

Further tests have shown that the drill with a 35-deg. helix angle retains its cutting edge at least as well as drills with helix angles of 22 and 26 deg. under usual drilling conditions, while it is more efficient in ejecting chips in drilling deep holes than drills with smaller helix angles.

As regards clearance, it has been found that a drill with a helix angle of 35 deg. and a clearance angle of 6 deg. has approximately the same quantity of metal in the cutting end as the 26-deg. angle drill with a clearance angle of 12 deg. (Fig. 4).

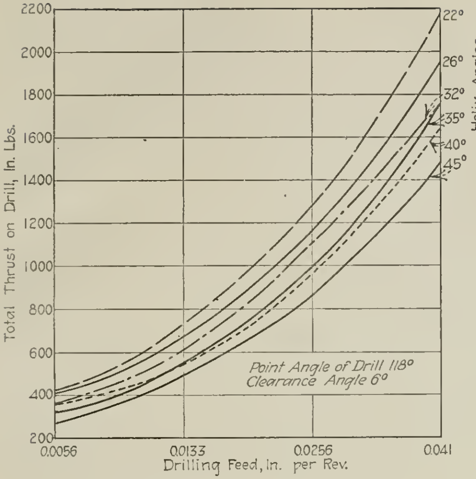

Fig. 3 Total End Thrust on 1-In. Drills of Various Helix Angles at Various Feeds in Cast Iron

twist drill has a helix angle of 35 deg. and that it is possible that development in the shape of the flute will lead to the employment

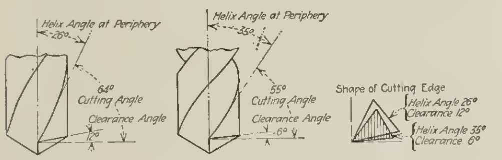

Fig. 4 Comparison of Cutting Angles of Usual and Proposed Designs of Drills

of helix angles above 35 deg. and the attainment of still greater efficiencies. (*American Machinist*, vol. 53, no. 26, Dec. 23, 1920, pp. 1175–1178, 5 figs., *epA*)

Sellers 16-Ft. Planer. Description of a machine tool remarkable for its size and some of the features of design, built by Wm. Sellers and Company, of Philadephia, for a large shipbuilding concern. The machine weighs nearly half a million pounds and is driven by a motor of 75 hp. capacity.

So large is the machine that in order to make its transportation possible it had to be made in several parts and assembled on the spot. This means that it had to be designed and built with particular care so as to make the maintenance of alignment possible.

In particular, the table is 13 ft. wide and was shipped in three lengthwise sections. The bearings on the table, one of which is flat and the other a V, are lubricated by oil delivered by a pump installed for this purpose only, which is, however, the standard practice of Wm. Sellers and Company.

The cross-rail has a span of 16 ft. between supports, which ordinarily might entail a vertical deflection due to the weight of the rail and saddles. In the machine under consideration, however, this is eliminated by giving the rail an extended-back type of construction which makes it very rigid and by the application of an arched girder bolted to the top surface of the cross-rail and provided with a solid abutment at one end and a wedged abutment at the other.

Another difficulty caused by the length of the cross-rail is the tendency of the screws and rods for moving the saddles to sag in the middle. To maintain their alignment, sliding bearings are used. These bearings, three in number, have an automatic position.

Instead of the ordinary bolts and nuts for clamping the cross-rails to the uprights, the work of clamping is done by pneumatic cylinders, each operating two bolts. The four cylinders are connected to a valve having a selective movement, permitting the cylinders to either open or close. After the cross-rail has been clamped the air passage may be released by the valve, as the clamps are so designed that they will not loosen until air is applied in the reverse direction. This is important, as should the air pressure fail at any time the clamp would otherwise relax and the work might be spoiled.

Other details are described in the original article. (*American Machinist*, vol. 53, no. 22, Nov. 25, 1920, pp. 973–976, 3 figs., *dA*)

MANAGEMENT

An Experiment with Rest Pauses, J. Loveday. Part of a report of the Industrial Fatigue Research Board. While the experiment covered a period of little more than six months, it is of considerable interest. The experiment was carried out at the plant of a firm having two factories, in one of which shoes were manufactured and in the other heels and stiffeners only.

In the stiffener and heel works all the employees with the exception of the foremen were women, the working hours in 1918 being 46 per week. In 1918 the firm found itself confronted with the problem of increasing output without adding new machinery, owing to the extreme difficulty of obtaining machinery at that time. The difficulty arose particularly in the press room where the leather is cut into pieces of the shape required by a mechanical press working upon a heavy knife of the requisite form. The presses are of two types, single and double, a double press being a bench with a press at either end. The operation demands skill and care: flaws in the leather must be avoided and the skin cut with as little waste as possible. The problem has been successfully solved by the adoption of the following plan:

It was determined to make the experiment of working the double presses with a team of three girls, each operative working 40 min. in each hour and resting 20 min., instead of with two girls working continuously throughout the day. It was hoped thus to increase the output of the machine—a hope which has been justified by results. The experiment was begun in January 1919 on a machine with results so favorable that in July six double presses were being operated on this system. A comfortable and attractively furnished rest room, quiet and restful in color, has been provided, and but for the difficulty of arranging for further rest rooms, a difficulty which can only be overcome by building, the plan would already have been greatly extended. There the girls, when they come down from work, are free to rest or to occupy themselves with crocheting, knitting, etc., as they may desire.

Six girls, one for each machine, go to the rest room on arrival at the factory in the morning, and do not start work until 8 o'clock; from then onward the period of rest is 20 min. in the hour throughout the day. Those whose turn it is to rest at 11.40 a.m., and at the corresponding period in the evening, are allowed to go home. The experiment was constituted with the consent of the operatives after thorough explanation, and, though somewhat skeptical at first as to success, they were willing to give it a trial.

The operatives are paid by day rate plus a bonus on output. This bonus is computed by calculating the weekly output of the press and dividing it into three equal parts, so that the three members of each team receive an equal bonus, proportional to the amount of work done during the week.

With the new arrangement a total increase of output on the six presses was obtained amounting to over 44 per cent, and this very high figure is attained with the reduction of the working hours of the individual operative by one-third, and without the addition of new machines. Sufficient data are not available to draw any accurate conclusions as to the actual increase or decrease in output of individual workers, but it would appear that there was such an increase. In particular, it appears that a change benefited especially the comparatively unskilled and the less robust workers, who otherwise would be more liable to fatigue.

As regards the effect on workers, it is stated that at first the girls did not believe the scheme would prove successful, and did not believe they could put out enough in such short hours. Experience, however, reconciled them to the system and none of them at the time of the investigation desired to return to the former hours. This was particularly so in the case of the weaker and less highly skilled girls. (*Report No. 10 of the Industrial Fatigue Research Board, Great Britain*, abstracted through *Engineering and Industrial Management*, vol. 4 (New Series), no. 23, Dec. 2, 1920, pp. 716–718, *gp*)

MEASURING APPARATUS (See Railroad Engineering)

Instrument for Indicating and Recording the Speed of a Railway Train

Recording Speed Indicators, A. G. Newell. While the recording speed indicator might be of great service in railroad operation, as the author points out, there are many elements some of which are of psychological rather than mechanical character which have so far interfered with its useful adoption. Some operating officials are rather reluctant to set a speed restriction and require its observance at all times. Engineers who are not familiar with the working of the speed recorder are also apt to look upon it with disfavor, even though they often change their opinion after becoming familiar with it, as they realize that an instrument of this kind eliminates taking of chances by the other fellow and puts each crew on the same basis.

A speed-recording device on the locomotive is of particular interest as it permits more certain and, curiously enough, more rapid operation over bridges in bad condition, slow track or curves. At present it is the practice of a good many foremen to place very slow limits of speed over bridges and parts of track undergoing repairs, in the expectation that enginemen will not hold their trains to the letter of the order and will in most cases make two or three times the speed that the order calls for, with the result that enginemen obedient to the order go at speeds very much lower than is actually necessary. The correct speed can be set and maintained, however, without difficulty where recording speed indicators are used.

The experience of the El Paso and Southwestern System is described in practice. Their experiments were started in 1907 with a Flaman tachograph brought from France. This instrument gave satisfaction and in 1911 three more of the same make were applied. These four instruments met with such success that it was decided to adopt them as a standard appliance for all road engines on the system. A mechanic was sent to the factory in France and made a thorough study of the instrument. A modern shop for testing and repairing was then fitted up at the general shops at El Paso, Tex. Since then 114 locomotives in road service have been equipped with the Flaman tachograph and there are sixteen reserve instruments on hand.

The apparatus has a speed-indicating dial graduated from zero to 90, each division representing one mile in speed. A small black pointer plays over the face of the dial, indicating the speed being made at all times when the engine is moving in either direction. The lower part of the case contains the speed- and time-recording mechanism and the recording tape, the record on the tape being made by two styles. A sample of a record is given in Fig. 5. The time-recording style rises from the bottom line to the top line in a given interval, which in various types of indicators may be either 10 or 30 min., making a sudden and vertical drop from top to bottom. The degree of inclination of the oblique lines made by the style depends on the speed being made, the greater the speed the less the inclination. During the time the engine is standing the time-recording style will move up in a vertical line or a series of vertical lines, each full line from bottom to top representing 10 or 30 min., depending on the tape used, and each fraction of a line its portion of time.

The mechanism of the instrument is of clockwork type and receives its motion from a series of springs which must be wound by the engineer by means of a small crank before the engine leaves the roundhouse track or at any time after the engine has stood for a period of 30 min. or more during the trip. When the engine is moving in either direction the clockwork is wound automatically by means of transmission rods and gears, receiving its motion from a driving stud and arm attached to the right back side-rod pin and will continue to run for a period of from 30 to 40 min. after the engine has stopped.

The instrument is so arranged that tampering with it is quite difficult. The cost of the apparatus at present is said to be $270 for each instrument and $193 for applying it. The average length of time an instrument will stay in service without repairs is about four months. (*Railway Review*, vol. 68, no. 1, Jan. 1, 1921, pp. 7–10, 4 figs., *d*)

MECHANICS (See Munitions)

MISCELLANEA

Power and Fuel Facts. The following figures are of great interest in that they emphasize in an unusual way the need for fuel conservation:

Prime movers of all kinds in U.S. (stationary and locomotive)	100,000,000 hp.
Used at average load factor of	14 per cent
Used for average period per week	23.5 hr.
Develop per year	125 billion hp-hr.
Water power available	50,000,000 hp.
Coal (without lignite) in ground	2500 billion tons
Petroleum in ground	7 billion bbl.
Used for power only (locomotive and stationary) on basis of present power delivered, resources will last:	
Water power, if all developed	indefinitely
Coal used by best practice	57,000 yr.
Coal used by average practice	7,500 yr.
Petroleum (allowing 40 per cent gasoline)	9.25 yr.
Of prime movers installed:	
Steam plants, coal-fired, make up	52 per cent
Hydraulic plants make up	8.2 per cent
Combustion engines and other types make up	39.8 per cent
Of power developed:	
Public utilities use	42 per cent
Manufacturing plants use	28 per cent
Railroads use	30 per cent
Of 1 ton of coal in the ground, or	2000 lb.
Best recovery brings to the surface	1900 lb.

By best large central stations	608 lb.
By best small central stations	304 lb.
By locomotives, best practice	175 lb.
By small individual plants, average practice	76 lb.

MOTOR-CAR ENGINEERING (See Internal-Combustion Engines)

MUNITIONS

The Aerodynamics of a Spinning Shell, R. H. Fowler, E. G. Hallop, C. N. H. Lock and W. H. Richmond. An extensive paper containing the results, theoretical and experimental, of work carried out by the Munitions Inventions Department for the British Ordnance Committee, on the motion of a spinning shell through air at velocities both greater and less than the velocity of sound.

A description is given of the motion of the spinning shell considered as a rigid body under the effects of gravity or the reaction of the air; this latter is supposed to be known in terms of the position and velocity coördinates of the shell and the state of the air through which it moves. The motion of the shell thus described is then compared with results of experiments and the more important components by the force system imposed by the air are determined numerically as functions of certain variables, such as the velocity of the center of gravity of the shell.

The aerodynamic problem of the motion of the shell alone forms the subject of the investigation and not the general hydrodynamic problem of the motion of the complete system formed by the shell and air together.

The actual experiments consisted of observations of the initial motion of the shell (more particularly the angular motion of its axis of symmetry) over a limited range near the muzzle of the gun. The velocities experimented with ranged from 40 ft. per sec. to 2300 ft. per sec. Using the values of the components so determined, the actual motion of the shell can be calculated with equal certainty in the more general cases which are inaccessible to direct and detailed observation.

One of the interesting parts discovered in the tests is that the spinning shell moves in a manner different from that of the motion of a top. (*Philosophical Transactions of the Royal Society of London*, Series A, vol. 221, no. A 591, pp. 295-387, 15 figs., *tdA*)

PNEUMATIC TRANSMISSION

Laws Governing Closed-Circuit Pneumatic Transmission

Fundamental Properties of Closed-Cycle Pneumatic Transmissions, Jacques de Lassus. The author attempts to establish the laws governing pneumatic transmission operating with a constant mass of gas in a closed circuit, and, in particular, the polytropic transformations occurring in such a transmission. The following notation is used: γ the coefficient of adiabatic or practically polytropic transformation; K the volumetric ratio of the two chambers, capacity and reservoir, or the ratio of the masses of gases initially present in these chambers; M_r and P_r the mass of the gas and the pressure in the reservoir at every instant; M_c and P_c the mass and the pressure at every instant in the capacity; P_i the initial pressure of compression; M_{ci} the mass initially present in the capacity, and M_{ri} the mass initially present in the reservoir.

With this notation the author presents the following laws which he designates as theorems.

Theorem I. In a pneumatic transmission operating with a constant mass of gas in a closed circuit comprising two chambers of given fixed dimensions, the pressure obtaining at each instant in one or the other of these chambers divided by the power γ of the mass of gas contained at the moment in the compartment is a *constant.*

This law may be expressed by the relations $P_c = A\,M_c^\gamma$, $P_r = CM_r^\gamma$, where $A = \dfrac{P_i}{M_{ci}^\gamma}$ and $C = \dfrac{P_i}{M_{ri}^\gamma}$. It is well to call attention in this communicating chambers where there is neither assistance from nor protection of external work and where the flow is governed only by the difference of pressures obtaining between the two chambers.

Theorem II. The power $\frac{1}{\gamma}$ of the pressure obtaining at each instant in the reservoir added to the power $\frac{1}{\gamma}$ of the pressure obtaining in the capacity multiplied by the coefficient K is a constant sum equal to the product of (coefficient K + unity) by the power $\frac{1}{\gamma}$ of the pressure at rest or initial pressure of compression. This law is expressed by the formula—

$$P_r^{\frac{1}{\gamma}} + KP_c^{\frac{1}{\gamma}} = (K+1)P_i^{\frac{1}{\gamma}}$$

Theorem III. The volumetric degree of compression ρ at the compressor which is variable at successive stages and which corresponds to any given stage K_n of the ratio of the masses of gas in the two chambers is equal to the inverse of the ratio $K_n \times$ the constant factor K. Moreover ρ is independent of the initial pressure of the charge.

$$\rho = \frac{K}{K_n}$$

Theorem IV. The value of K_m, which is the ratio of the masses of gas respectively contained in the capacity and the reservoir in a state which corresponds to a maximum output of work per revolution of compressor, is a function exclusively of K and of the coefficient γ of transformation.

$$K = \frac{\gamma^{\frac{1}{\gamma-1}}K_m}{[1-(\gamma-1)K_m]^{\frac{1}{\gamma-1}}}$$

From this law one can see that the ratio ρ_m which corresponds to the maximum couple at the compressor is a function of only K and γ.

Compensation of Leakages. If we raise to the power γ the two members of the formula which express the second law and if we express the first member in the form $P_r\left(1+\dfrac{K}{\sigma}\right)^\gamma$, we obtain a binomial expression $(X+1)^m$, where X, which is a variable, has its values comprised between 0 and 1 if K is, for example, less than 4. Since m has a value not in the immediate neighborhood of unity, we arrive by developing the expression in a Taylor series at an expression $P_r + MP_c$ = constant, where the coefficient M has a value close to K raised to the power of γ.

This expression means that if we act on a piston in two stages of which the sections are in the ratio M with the pressure P_r constantly applied on the smaller section and the pressure P_c constantly on the large section, the piston will remain in equilibrium under the action of constantly applied opposed forces. This device makes it possible to insure the invariability of the gaseous mass in the circuit. As soon as a noticeable leak occurs or as soon as the average internal energy of the gaseous mass tends to deviate at any prevailing state from the scale of values established by the theory presented above, the two-stage piston becomes immediately possessed of a tendency toward displacement in one or the other direction, and its displacement may then be used to provide a communication respectively between the capacity or reservoir and a charging or exhausting compartment, according to the direction of the displacement of the piston. Such a piston insuring the invariability of the gaseous mass in the circuit and having the ability to return to its position of rest whenever the cause of disturbance disappears, is called a "pneumatic balance." At all states of operation it plays the double rôle of a device for automatically compensating for losses and of governor in the operation of the circuit.

Operation under Different Initial Potentials. If the regulation of the distribution of the receiver is constant, then in accordance with the third law the same ranges of velocities and couples will be obtained with the same apparatus, no matter what may be the

initial potential of the charges; that is, no matter what may be the power which the group must deliver for a given velocity of the compressor. In other words, the apparatus is absolutely comparable with itself, no matter what may be the value of P_i; in particular (Theorem IV), the maximum of the motor couple at the compressor preserves the same location between the extreme points in the operation of the transmission. Therefore, within practical limits determined by the strength of materials employed, the same transmission may be used for a wide range of power, simply by varying the spring or the counter pressure of the pneumatic balance in such a manner as to modify the constant of its equation of equilibrium without, however, changing the average position of equilibrium of its balance; that is, without changing anything in the arrangement of the different organs of the apparatus. (*Comptes Rendus des Seances de l'Academie des Sciences*, vol. 171, no. 21, Nov. 22, 1920, pp. 992–995, *tA*)

STEAM ENGINEERING

Tests of the Unaflow Pumping Engine, D. A. Decrow. Description and data of tests carried out on an experimental engine with a view to determining certain factors. The engine is a single-cylinder, horizontal crank-and-flywheel pumping unit of the extended type having a nominal capacity of $2^1/_2$ to 3 million gallons in 24 hours. The engine itself has a steam cylinder $13^1/_2$ in. in diameter by 21 in. stroke.

The main data are presented in the original article in the form of tables and the results would appear to indicate that the permissible speeds of this type of engine are much higher than is considered advisable for other types of crank-and-flywheel pumping engines. The results of the steam economy would also indicate higher economy for the higher speeds and temperatures. (*Journal of the New England Water Works Association*, vol. 34, no. 3, Sept. 1920, pp. 195–199, *e*)

TESTING APPARATUS

Junkers Water-Eddy Brake. Description of a water brake of the eddy type employed in the testing laboratory of Doctor Junkers for testing oil engines with a power output of the order of 1000 hp. Essentially, the brake consists of the rotor A (Fig. 6)

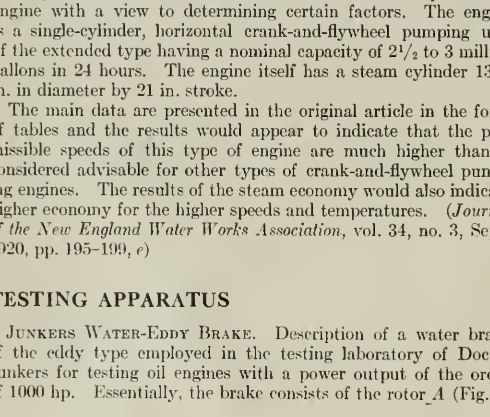

Fig. 6 Junkers Eddy-Type Water Brake
(*Wage* = Scale)

keyed on a shaft and a stator B located centrally with respect to the shaft. The stator and rotor are provided along their peripheries with finger-like attachments arranged in a certain manner, water being circulated between these attachments. If now the rotor A be set in rotation the water between the finger-like attachments offers a resistance which converts the energy supplied by the motor into heat, and this heat is in its turn carried away by the water. The brake has therefore no solid parts rubbing against each other. The thickness of the water rings determines the output which the brake is capable of handling and the regulation is carried out in a very simple manner by varying the level of the water rings, this being done by regulating the water inlet and outlet valves. Preferably the water admission is so regulated that no steam is produced, as this would make conditions in the test room unpleasant.

If water is admitted at 10 deg. cent. (50 deg. fahr.) and discharged with an outlet temperature of 65 deg. cent. (149 deg. fahr.) then the brake will require 636/55 = 11.6 kg. [2545/(149–50) = 25.7 lb.] of water per b. hp-hr. The brake is equally suitable for all kinds of motors, outputs and speeds. Thus the original article illustrates a brake of this type applied to the testing of an exhaust-steam turbine of 6400 hp. at 210 r.p.m. Another illustration shows a 600-hp. Diesel motor, etc. One of the advantages claimed for this brake is that it prevents the engine from running away under any conditions whatsoever. (*Wirtschafts-Motor*, no. 9, Sept. 1920, pp. 19–20, 5 figs., *d*)

VENTILATION

Determination of Dust Content of the Air in a Room

Theory of Dust Action, O. W. Armspach. Report of investigations on air dust and its determination carried out jointly by the research bureau of the American Society of Heating and Ventilating Engineers and the United States Bureau of Mines.

Dust for the purpose of the investigation is defined as particles of matter so finely divided that they easily remain suspended in air, and the velocity of fall is comparatively low. They are considered as spheres. The length of the time that a particle remains in suspension depends upon its diameter, its density, and the density and viscosity of the air.

The following important conclusions have been established:

1 The dust content in a room depends upon the density of the material, velocity of fall of the particles, and the size of the room; the dust will accumulate until a definite content is reached, depending upon the rate of fall and the number of air changes,

2 The total dust given off by various machines when handling different materials can be determined from the average count resulting in the room;

3 Dust conditions can be greatly improved by providing the proper number of air changes; there is, however, a limit to this number and usually five changes per hour are sufficient;

4 For equal conditions of air dustiness, as the density of the material increases, the weight per cubic foot decreases;

5 All dust determinations should be on a basis of the number of particles per cubic foot.

A formula is derived for the velocity of fall of dust particles in terms of their radii and density and the density and viscosity of air. A chart constructed from the formula for various kinds of dust is represented in Fig. 7. It will be observed, for example, that a particle with a diameter of 2 microns and a density of 8, will fall at the same rate as a particle having a diameter of 5.75 microns and a density of 1. With a constant density the velocity increases as the size of the particle increases, and the increase in velocity becomes greater as the diameter becomes greater; that is, for the larger particles the friction of the air is less effective and the velocity of fall more nearly equals that due to gravity. Fig. 7 further shows that the density of the dust particle is an important factor when the conditions of air dustiness in a room are considered. Particles of iron dust 2 microns in diameter will fall at a rate of 12 ft. per hour, whereas particles of wood dust of the same size would fall only $1^1/_4$ ft. per hour. Therefore, when equal quantities of wood and iron dust are produced in different rooms, the conditions of air dustiness in these rooms will differ considerably. The average size of the particles in a steel-grinding establishment will be very much smaller than the size of the particles in a furniture factory, and the means of controlling the dust as necessary to maintaining desirable conditions in the various establishments must be compatible with the fineness and the density of the material handled.

It follows that the average dust count in a room will depend upon the kind of material, the conditions at the source, velocity of fall, and the length of time that the dust-producing machines have been in operation. Formulas are derived and graphs constructed indicating the number of particles of various kinds of dust in a cubic foot of air in a room of given capacity with equally unfavorable conditions at the source. It is thus determined that the heavier dusts reach the maximum-content conditions early in the day, while for wood and other lighter materials the dust content continually increases even after the tenth hour is reached. A dust count alone is therefore not sufficient when designing a

So far the effects of the conditions at the source of dust and the velocity of fall of the particles have only been considered. In addition, there is a decrease in the dust content due to the change of air in the room. This change may result from natural infiltration of air from outdoors or by exhausting the air from the room by mechanical means. When air leaves the room, each cubic foot carries with it a certain number of particles, depending upon the dust content in the room. Also an equivalent amount of air must enter the room. There is therefore a continuous process of dilution taking place, and the dust content in the room

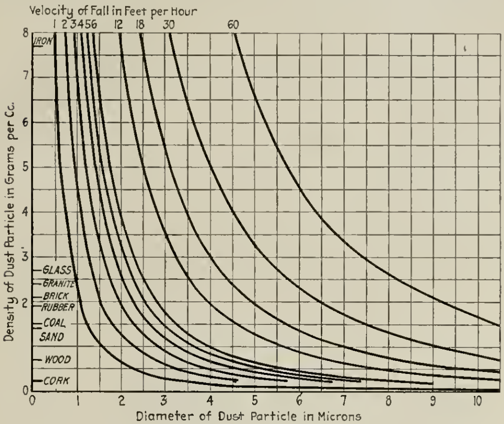

Fig. 7 Chart Showing Velocities of Fall for Various Kinds of Dust

is decreased. When the dust leaving the room due to the air change, plus the dust falling from the room, is equal to the total dust liberated, the conditions are balanced and the dust content in the room remains constant. Fig. 8, also constructed from a formula, shows the effect of changing the air on the dust content. The curves have been plotted for dust 2 microns in diameter falling with a velocity of 1 ft. per min., and 100,000 particles per

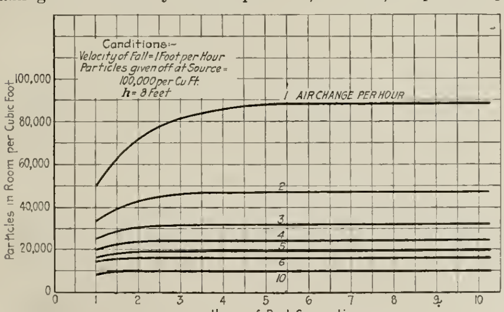

Fig. 8 Curves Showing Effect of Air Change on Dust Content

cu. ft. per hour are given off at the source. Note that with one air change the result in the room at the end of the fifth hour is 88,000 particles per cu. ft. With two air changes the result is only 47,000 particles. If no air is allowed to enter the room the result will be 389,600 particles per cu. ft., or an increase of 342 per cent over the result obtained with one air change.

It will be readily seen that counting methods are superior to weight measurements in air-dust determinations. It is possible to have very different weights for the same conditions of dustiness with different dusts. For example, the weight of 100,000 particles of iron dust of a size which could cause them to fall at the rate of terial, the greater must be the weight per cubic foot to result in equal conditions of dustiness. Thus a dust determination based upon weight is extremely misleading. (*Journal of the American Society of Heating and Ventilating Engineers*, vol. 26, no. 9, Dec. 1920, pp. 819–829, 6 figs., *t*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

Attaining Normal Grinding Speeds With Extremely Small Wheels

A grinding-wheel spindle designed to operate at 104,000 revolutions per minute was exhibited at the recent London machine-tool exposition. *Machinery* for January 1921 describes this spindle, which is equipped with a wheel $^1/_4$ in. in diameter, attaining, therefore, a cutting speed of about 6800 ft. per min. It is the product of the A. A. Jones & Shipman Co., Leicester, England. The drive is from an electric motor running at 2500 r.p.m. through an intermediate shaft which runs at 9150 r.p.m. Each bearing contains 12 balls of $^1/_8$ in. diameter. The balls are not caged. A special kind of rubber is used for the driving belts. The spindle apparently reaches its critical speed at 33,000 r.p.m., as when it attains approximately this speed the belt starts to oscillate badly; as the speed increases, however, this effect dies down and the belt again runs smoothly. This spindle is yet in the experimental stage, but it has been run hour after hour without undue heating, the period being apparently limited by belt endurance. The wheel was not cutting during these runs.

A more definite stage of practicality has been reached with the next size of spindle, which is provided with the same type of cup and cone bearings designed to run at 40,000 r.p.m. and fitted with a $^1/_2$-in. wheel to give a surface speed of approximately 5000 ft. per min. This spindle is regularly in work at the maker's plant and is said to have been operated at 37,312 r.p.m. grinding out hardened steel gears, with a band of rubber that had stood for three working days without stretching or warping. This spindle has been tested by the National Physical Laboratory up to a speed of 45,460 r.p.m.

The University of Wisconsin has established a Bureau of Commercial and Industrial Relations which will provide information or service in this field. A series of bulletins treating with the following subjects are in process of issue at monthly intervals.

- A Labor Policy and The Labor Audit
- Job Analysis
- The Cycle of Employment
- Industrial Housing
- Government in Industry
- Underemployment and Absenteeism
- Wages and Earnings
- Insurance and Pensions
- Industrial Training and Vocational Guidance
- Industrial Housekeeping
- Plant Newspaper
- Industrial Safety and Hygiene.

In addition to the above circulars a Bibliography Service will be developed. Arrangements are being made to carry forward special Research Service and to make the results available to those interested. A plan is being worked out whereby advanced students may be detailed to special projects in industrial units, working under the close supervision of the Industrial Relations Bureau.

An Analysis of Machined Fits

A.E.S.C. Sectional Committee Acting Through One of Its Sub-Committees Presents a Comprehensive Questionnaire to American Industry

THE July 1920 issue of MECHANICAL ENGINEERING announced the organization and the personnel of the Sectional Committee on Plain Limit Gages for General Engineering Work, a Sectional Committee which is working under the Rules of Procedure of the American Engineering Standards Committee and is sponsored by The American Society of Mechanical Engineers. After a preliminary canvass of the gaging situation carried on during the summer months, the Committee subdivided itself into three working sub-committees. To these sub-committees have been assigned the three subdivisions of the subject, viz., (*a*) standards and tolerances for manufactured material; (*b*) methods of gaging manufactured material; and (*c*) gages and their limits, manufacture, and use.

The Sub-Committee on Standards and Tolerances for Manufactured Material, to which has been assigned the task of preparing a set of standard allowances and tolerances for mating parts in interchangeable manufacture, has after considerable discussion and consultation with manufacturers prepared a questionnaire, full and complete, answers to which it earnestly requests. Since by the method of its organization the report of the full Committee when approved by the A.E.S.C. will establish American standard practice, it is very desirable that everyone interested in any way in this set of standards should know of this activity and should have a part in it, if he so desires. MECHANICAL ENGINEERING therefore takes pleasure in reprinting this questionnaire in full and invites its readers to send their replies addressed to the Committee, care of The American Society of Mechanical Engineers, 29 West 39th Street, New York City.

QUESTIONNAIRE

For the purpose of clearness and after very careful consideration, the Committee has subdivided all machined fits into four classes. These are listed below with the kinds of work which seem to fall in each class.

CLASS NO. 1 LOOSE FITS

Machined fits of agricultural, domestic, and other machinery of similar grade (wagons excepted)
Mining machinery
Controlling apparatus for marine work, etc.
Textile and rubber machinery, candy and bread machinery and others of similar grade
Some parts of ordnance
General machinery for manufacturing.

Question 1. What allowances do you make in this class?

CLASS NO. 2 MEDIUM FITS (Moving Parts)

2 *a* High Speeds (over 600 r.p.m) and Heavy Pressures

Electrical machinery
High-speed parts of woodworking machines
Sewing machines
Machine tools
Locomotives
Printing machinery
Automotive
Ordnance
General machinery for manufacturing.
A well-known firm uses allowances of 0.0005–0.004 in. up to 6 in. for work of this class.

Question 2. How does this compare with your practice?

CLASS NO. 2 MEDIUM FITS

2 *b* Ordinary Speeds (under 600 r.p.m.) and Light Pressures

Machine tools
Printing presses and machinery
Typewriters, calculating machines, etc.
Locomotives
Automotive—general parts
Textiles, rubber machinery
Ordnance
General machinery for manufacturing.
A well-known firm uses allowance of 0.0005–0.0025 in. up to 6 in. for work of this class.

Question 3. How does this compare with your practice?

CLASS NO. 3 SNUG FITS

(Designated as the closest fit that can be assembled by hand.)

3 *a* *Slight Allowance* (0.00025 to 0.00075 in.)

Gear trains and change gears for general work
Mating parts, fixed or not, moving on each other, such as studs for gears and levers, keys
General machinery for manufacturing.

Question 4. Do these allowances agree with your practice?

3 *b* *Close Fit* (commonly known as wringing fit, no allowance, not considered interchangeable manufacturing but selective assembling)

Crankshafts
Precision-ground machine spindles
Gears in index train of precision gear-cutting machines
Slots and tongues such as are used for grinding machines, milling machines, etc.
Surveying and scientific dental instruments, etc.
General machines for manufacturing.

Question 5. Should no allowance be made in machining the fits in this class?

CLASS NO. 4 TIGHT FITS

4 *a* *Drive Fits* for Light Sections

Automotive
Ordnance
General machines for manufacturing.
A well-known firm uses negative allowance from 0.00025 to 0.001 in. up to 6 in.

Question 6. How does this compare with your practice?

4 *b* *Force Fits* for Heavy Sections

Locomotive and car wheels
Crank disks, armatures, flywheels
Automotive
Ordnance
General machines for manufacturing.
A well-known firm uses negative allowance from 0.00075 to 0.005 in. up to 6 in.

Question 7. How does this compare with your practice?

4 *c* *Shrink Fits*

Locomotive tires and similar work
Ordnance.
A well-known concern's practice is as follows: Where thickness exceeds $^3/_8$ in., 0.0005 to 0.005 in. up to 6 in. in diameter. Where thickness is less than $^3/_8$ in., up to 6 in. in diameter, 0.00025 in. to 0.0015 in.

Question 8. How does this practice compare with yours?

The Committee would greatly appreciate having your full answers also to the three following general questions with as much explanatory information as possible:

Question 9. How many of the four kinds of fits previously mentioned apply to your work?

Question 10. Will you send the Committee blueprints or other data showing your practice in as many of these cases as possible?

Question 11. How do you specify both allowance and tolerance for mating parts—such as a solid 2-in. bearing and the shaft which runs into it?

The following sketches show some of the problems. Will you kindly give the Committee as much information as possible regarding your practice in such cases.

Question 12. What allowance and what tolerance would you give on such a piece as shown in Fig. 1: (*a*) for a milling-cutter arbor, (*b*) for a work-holding mandrel?

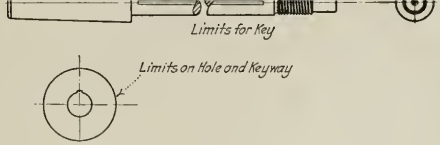

Fig. 1

Question 13. What allowance and what tolerance would you give on the keys and keyways shown in Fig. 2, where
(*a*) Keys are tight in both shaft and hub;
(*b*) Keys are tight in shaft—sliding in hub;
(*c*) Keys are tight in hub—sliding in shaft?

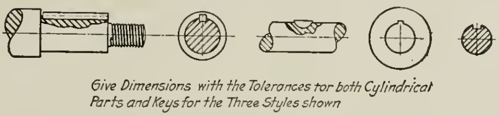

Fig. 2

Question 14. What difference in allowances and tolerances would you give on the bearing and gear fit shown in Fig. 3?

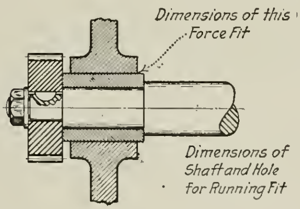

Fig. 3

The fit of a wrench is shown in Fig. 4.

Question 15. What is your practice as to allowance and tolerance for maximum looseness and maximum tightness?

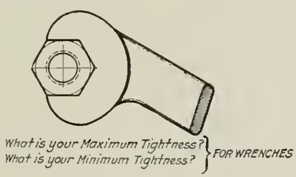

Fig. 4

The rocker arm shown in Fig. 5 contains several kinds of fits.

Question 16. What allowance and tolerance would you give at *A*, *B*, and *C*?

Two shrink fits are shown in Figs. 6 and 7, one a thin shell, the other a locomotive tire. The latter also has a press fit.

Question 17. What is your practice on work of this or a similar character?

In multiplying movements the lost motion often plays an important part.

Question 18. What is your practice in such cases as shown in Fig. 8—for both allowance and tolerance?

Fig. 9 shows a light sliding fit for accurate grinding or similar work. Fig. 10 illustrates a working slide fit for turret slide or for similar purposes.

Question 19. What are your allowances and tolerances in such cases?

Question 20. Do they vary with the length of the slide?

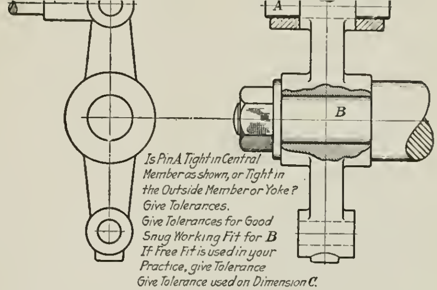

Fig. 5

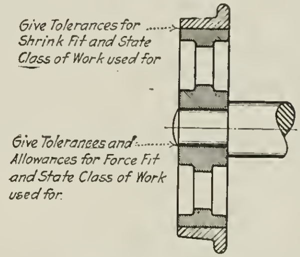

Fig. 6

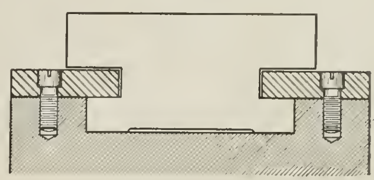

Fig. 10

(*Continued on page 144*)

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A.S.M.E.

Research Committee Notes

THE Special Committee on the Strains due to the Vibration of Shafting will probably organize during the present month under the chairmanship of Mr. N. W. Akimoff. The work of this committee is most important owing to the fact that within recent years a number of failures of the main shafts of vessels have failed from this cause. The committee plans to collect the present knowledge on this subject and then to complete the work as far as possible for the use of the engineering profession.

The Committee on the Present State of the Knowledge Regarding Riveted Joints, under the chairmanship of Dr. A. D. Risteen, will also begin work soon. It is not expected that these two committees will report within two years on account of the amount of work to be done.

The Research Committee plans to use the library of the United Engineering Society and any other collection of data for the work of these committees, and would welcome suggestions from members of the Society regarding problems which demand investigation.

The Scovill Bulletin

The Scovill Manufacturing Company, Waterbury, Conn., has issued as a supplement to the Scovill Manufacturing Company Bulletin, a pamphlet of fifteen pages giving a short description with a photograph of its chemistry and test building, and a paper on the application of metallurgy to the brass industry. The paper includes halftones showing the peculiar nature of alloyed metals and the effects of improper handling during the course of manufacture. The effect of annealing, of continued heating at high temperatures, of improper casting practice, of improper annealing, of improper manufacturing methods and the results of experimental annealing are illustrated in the halftones. The pamphlet also contains halftones showing part of the equipment of the laboratory and explains how the microscope can be an aid in the manufacturing department. Mention is made of the diseases of metals, also of casting, shop problems and the selection of the proper metal for particular pieces of work.

Report of British Inquiry Committee on Lubricants and Lubrication

The Report of the Inquiry Committee on Lubricants and Lubrication has now been published for the Department of Scientific and Industrial Research by H. M. Stationery Office.

The Committee was set up as the outcome of an application made to the Advisory Council for a grant in aid of proposed researches to determine the relation between the viscosity of lubricants and the load on a bearing, and the action of lubricants at high temperatures as applied to commercial methods of oil testing. The Advisory Council deprecated an attempt to obtain partial results in any section of the field for research in lubrication and recommended that an Inquiry Committee be set up under the Department to prepare a memorandum on the field for research, containing an analysis of the problems involved together with a suggested scheme of research which would be likely to lead to valuable results.

The Report of the Committee under these terms of reference is now published and is divided into the following sections:

1 Introductory
2 Bibliography
3 Research work instituted by the Committee
4 Bulletins
5 Existing knowledge of lubrication
6 Review of existing knowledge
7 Recommendation for future research on Lubricants and Lubrication
8 Liaison with the American Bureau of Standards
9 Conclusion.

Subjoined to the Report are 20 appendices by various authors which contain particulars of a number of researches instituted by the Committee on certain fundamental problems on which knowledge was lacking.

Copies of the report (price 2s.6d., by post 2s.8½d.) may be obtained through any bookseller or directly from H. M. Stationery Office at the following addresses: Imperial House, Kingsway, London, W. C. 2, and 28 Abingdon St., London, S. W. 1; 37 Peter St., Manchester; 1 St. Andrew's Crescent, Cardiff; 23 Forth St., Edinburgh; or from E. Ponsonby, Ltd., 116 Grafton St., Dublin.

Research Résumé of the Month

A—Research Results

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a résumé of research results with formulas or curves where such may be readily given, and to report results of non-extensive researches which in the opinion of the investigators do not warrant a paper.

Apparatus and Instruments A2–21. Artificial Seasoning of Gage Steels. An investigation has been made by the Bureau of Standards on various seasoning treatments on the permanence of gage steels. Various hardened gages were heated in oil at different temperatures under varying time conditions and subject to seasoning by dipping in hot oil and iced brine. Short gages of 1/8 in. showed no appreciable change in length with or without various artificial seasoning treatments over a period of seven months beginning one or two weeks after hardening. Length gages of 2 in. showed no appreciable change in planeness. For studying length change it has been shown that lengths from 6 in. to 8 in. are desirable.

Duplicate gages show wide variations in length change. One block showed no dimensional change in 217 days between first and last measurement, while a duplicate decreased 0.00018 in. in the same period. On account of softness, stainless steel is unsatisfactory. Higher-carbon alloys of this type would be more desirable, with a possible decrease in chromium which would not impair the stainless qualities and at the same time reduce the production cost. Plain carbon steel of 1.18 per cent carbon appears least desirable from the standpoint of permanence. The most desirable steels are HC and K, subject to different seasoning treatments. Measurements at intervals of one week, 1, 2, 4, and 7 months after initial measurements of length and planeness do not give very much information regarding the progress of the changes taking place. Where great changes occur they appear to progressively increase with time. Many changes occur immediately following the first measurements. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Cement and Other Building Materials B2–21. Reinforced-Concrete Slabs. The Cement Gun Company, Inc., of Allentown, Pa., has issued a pamphlet of thirty-two pages on the Strength of Gunite Slabs. The formula used for these slabs has been checked under the supervision of Prof. M. O. Fuller, of Lehigh University, by a number of tests of slabs of 4-ft. span, 6-ft. span and 8-ft. span. The pamphlet contains data for balance percentage of reinforcement, safe loads for gunite slabs with a factor of safety of 4 with 1:3 mix and 1:2½ mix, and safe live loads for factor of safety of 5 with a 1:3 mix. The tables give the thickness of the slabs and the area of reinforcement per foot of width of slab. The pamphlet contains an analysis of the data by George F. Strehan and the report of Professor Fuller with tables containing the data obtained on the tests from the slabs, the cement and the sand used, as well as curves giving the results of the tests and photographs showing the method of testing. Address Cement Gun Company, Allentown, Pa.

Cement and Other Building Materials B3–21. Floor Treatment. The Bureau of Standards has issued a report on the service tests of various floor treatments carried out by the Bureau. The first materials were applied to the floors of the Northwest Building of the Bureau of Standards five months after its completion in March 1918. The sections were panels 8 ft. square and extending the width of the corridor and

Fluosilicate, Indurite, Liquid Concrex, Esco, Bilchaco, Concreto, Minwax, Thermowax and Saum's Preservative, produced by different manufacturers, and simple materials made at the Bureau of Standards such as sodium silicate, aluminum sulphate, linseed oil, fuel oil and soap and soap treatment.

The results of the home-made solutions are given below from A to J and U and V, while the other results are from the manufactured materials mentioned above under their trade names.

A. A treatment of 15 per cent solution of magnesium fluosilicate applied in three coats gave a surface which was quite hard after two years and three months of service with no wear showing except for a few small areas. The first coat was one part solution and two parts water; the second coat was one part solution and one part water; the third coat was two parts solution and one part water.

B. An 8.7 per cent solution of magnesium fluosilicate applied in three similar coats has been in use for one year and nine months. This shows considerable wear.

C. A $14^1/_2$ per cent solution of magnesium fluosilicate applied once in a heavy coat has been used for two years and two months and appears to be in a good condition. No wear is apparent.

D. A treatment of $11^1/_2$ per cent solution of magnesium fluosilicate in three coats shows no definite signs of wear after one year and eight months.

E. An 18 per cent solution of magnesium fluosilicate with a small amount of zinc fluosilicate applied in three coats gives no appreciable wear after two years of service.

F. A solution of 7.3 per cent magnesium fluosilicate with 2.6 per cent magnesium sulphate and $4^1/_2$ per cent of free hydro fluosilicate is unsatisfactory.

G. A 16 per cent solution of zinc sulphate with about $4^1/_2$ per cent of free sulphuric acid applied without dilution in two coats has given excellent satisfaction after two years and three months of service. After the first application had dried for four hours the surface was scrubbed with hot water and mopped dry before the application of the second coat. This gave a darker appearance to the original concrete.

H. A 20 per cent solution of sodium silicate containing small addition of organic acid applied without dilution in two coats 24 hr. apart gave excellent results after two years and two months of service. This treatment gave a brighter and more uniform appearance than the original concrete.

I. A treatment of 8 per cent solution of commercial sodium silicate in three coats if preceded by a thorough scrubbing with water gives excellent service after two years and two months. The treatment gives a hard surface of uniform appearance which is lighter in color than the original.

J. A 15 per cent solution of aluminum sulphate applied in three diluted coats gave satisfactory results after one year and six months of service. The surface is not so hard as that obtained by other treatments, but it is effective in holding dust. It is applied without interfering with traffic. The first coat was one part solution to two parts water, the second coat was one part water to one part solution and the third coat was two parts solution to one part water.

K. Gray paint of proprietary make containing lead sulphate, siliceous matter and carbon in varnish vehicle is showing the effects of wear after two years and two months service.

L. A china wood-oil varnish applied in two coats 24 hr. apart has been in service two years and one month with few scratches due to moving machinery. It is wearing thin in places.

M. China wood-oil varnish in two coats applied two years and two months show no appreciable wear.

N. Boiled mineral spirits varnish applied in two coats at intervals of 24 hr. in service two years and one month is worn in places.

O. Gray paint with pigment of basic lead sulphate, zinc oxide, barium sulphate, siliceous matter and carbon in linseed oil, rosin vehicle thinned with mineral spirits, applied in two coats, shows no signs of wear except scratches from machinery after one year and five months. Waxlike finish but not especially resistant to scratching, although under foot traffic.

P. Thick paint of zinc oxide, lithopone and bone black in varnish vehicle containing rosin. Only one coat was used but the directions require two coats. After one year and six months large scratches from machinery were noted. Thick film gives a surface pleasing to walk upon. Small spots have blistered and worn away.

Q. A solution of heavy carbon wax in light carbon oil applied in two coats. After two years and three months it was considerably worn. Object of this treatment is to hold dust and not to harden surface.

R. Treatment of mixture of waxes applied in molten condition worn through under office chairs. Considerable wear after two years and four months.

S. Linseed oil with small addition of citronella applied in first coat and kept dry. Test does not show true value of treatment.

T. Four applications of raw linseed oil thinned with turpentine. Service two years and two months. Results at first not satisfactory but surface hardens gradually and at present is quite hard. It appears to resist the wear very well.

U. Examination of slab subject to frequent scrubbings with thick soap solution. No polished condition results from this under wear.

V. Treatment of emulsion of fuel oil and soap of three quarts of harder than original. Application leaves floors slippery for a few hours.

Conclusions:

1 Materials of the magnesium fluosilicate class gave very good results although more knowledge is needed concerning proper strength of solution.

2 Zinc sulphate treatment gives excellent results.

3 Surface-coating materials are most effective in entirely eliminating dust.

4 Home treatments I and J prove very successful and quite inexpensive. The following directions are given:

A—Sodium Silicate Treatment

Commercial sodium silicate usually varies in strength from 30 to 40 per cent solution. It is quite viscous and has to be thinned with water before it will penetrate the floor. In ordinary cases it will be found satisfactory to dilute each gallon of the silicate with four gallons of water. The resulting five gallons may be expected to cover 1000 sq. ft. of floor surface one coat. However, the porosity of floors varies greatly and the above statement is given as an approximate value for estimating purposes.

The floor surface should be prepared for the treatment by cleaning free from grease, spots, plaster, etc., and then thoroughly scrubbed with clear water. To get the best penetration the floor should be thoroughly dry, especially before the first application, and if practical it is well to let it dry for several days after the first scrubbing. The solution should be made up immediately before using.

It may be applied with a mop or hair broom and should be continuously brushed over the surface for several minutes to obtain an even penetration. An interval of 24 hr. should be allowed for the treatment to harden, after which the surface is scrubbed with clear water and allowed to dry for the second application. Three applications made in this manner will usually suffice, but if the floor does not appear to be saturated by the third application a fourth should be applied.

This treatment when properly applied gives a very hard surface that is bright and uniform in appearance. The commercial sodium silicate can be obtained from wholesale druggists usually at a cost of 40 cents or less per gallon.

B—Aluminum Sulphate Treatment

The solution of aluminum sulphate for this treatment should be made in a wooden barrel or stoneware vessel. The amount required may be estimated on the basis of one gallon of solution for each 100 sq. ft. of area. For each gallon of water $2^1/_2$ lb. of the powdered sulphate will be required. The water should be acidulated with commercial sulphuric acid by adding 2 cc. of the acid for each gallon. The sulphate does not dissolve readily and has to be stirred occasionally for a period of a few days, until the solution is complete.

The floor should be cleaned of grease spots, plaster, etc., then thoroughly scrubbed. When the surface is entirely dry, a portion of the sulphate solution may be diluted with twice its volume of water and applied with a mop or hair broom. After 24 hr. dilute a portion of the original solution with equal volume of water and apply in the same manner as the first. Allow another interval of 24 hr. and make an application using two parts of the sulphate solution to one part of water. Each application should be continually brushed over the surface for several minutes to secure a uniform penetration. After the third application has dried, the surface should be scrubbed with hot water. This treatment will give good results at a cost about equal to that of the sodium silicate treatment. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Chemical, General and Physical A1–21. Inflammability of Jets of Hydrogen and Inert Gas. An article by P. G. Ledig, *Journal of Industrial and Engineering Chemistry*, vol. 12, page 1098, gives the following:

Under favorable conditions a jet of helium containing more than 14 per cent of hydrogen can be ignited in the air.

Eighteen to twenty per cent of hydrogen may be mixed with helium without producing a mixture which will burn with a persistent flame when issuing from an orifice under the conditions prevailing in balloon practice.

More than twenty per cent of hydrogen can not be used in balloon practice without sacrificing safety from fire. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Light A1–21. Personal Error in Using Parallel Cross-Hairs in Micrometer Microscope. The Bureau of Standards has recently made observations on the diameter of wire employed in certain sieves, using a micrometer microscope setting two parallel cross-hairs so that the edge of the wire was midway between them. Five observers were used. The results showed an evident personal error, confirming the metrological principle that it is difficult to match an equal width of bright and dark space. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Metallurgy and Metallography A3–21. Decarburization of Steel by Heating in Vacuo. Steel specimens heated for 24 hr. at approximately 760 deg. cent. had carbon content reduced from 0.54 per cent to 0.36 per cent. Material was an iron-carbon alloy prepared at the Bureau of Standards to which no addition other than carbon had been made. An explanation for this action assumes the presence of

oxygen in some form, as commercially prepared steel which has been deoxidized in manufacture behaves very differently from the small melts made at the Bureau. This investigation is being continued. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Metallurgy and Metallography A4–21. Magnesia for Crucibles Used with Electrolytic Iron and Iron-Carbon Alloys. The Bureau of Standards has prepared 100 lb. of electrolytically fused magnesia which contains less than 0.02 per cent SiO_2. This is not large enough to prevent the use of magnesia in melting electrolytic iron and iron-carbon alloys. Crucibles of fused MgO undergo so little shrinkage that it is possible to melt in the tamped and dried crucible without the preliminary calcination to 1500 or 1600 deg. cent. which was necessary with the old type of crucible. Samples of zircon have been obtained to compare with zirkite. These two zirconium refractories are at present obtainable commercially. The preliminary tests showed that refined zircon has a melting point considerable below zirkite cement. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Metallurgy and Metallography A5–21. Grain Size and Brinell Hardness of Carbon Steel. A paper on relation of grain size to Brinell hardness of annealed carbon steel by Rawdon and Jimeno has appeared in printed form and is ready for distribution. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Metallurgy and Metallography A6–21. Arc-Fused Steel. *Chemical and Metallurgical Engineering* for Oct. 20, 1920, contains the second installment of results of an investigation on the metallography of arc-fused steel conducted at the Bureau of Standards. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

B—Research in Progress

The purpose of this section of Engineering Research is to bring together those who are working on the same problem for coöperation or conference, to prevent unnecessary duplication of work and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

Metallurgy and Metallography B2–21. Heat Treatment of Carbon Steel. The Committee on Heat Treatment of Carbon Steel of the Division of Engineering, National Research Council, is continuing its work on this subject. Many tensile test pieces and impact test pieces have been used. Materials used have been investigated for magnetic properties and all materials have had the preliminary heat treatment. The heat treatment of the specimens has been accomplished in a special furnace and care has been exercised to determine the temperature of treatment very accurately. Address Dr. Henry M. Howe, Chairman of Committee, 29 West 39th St., New York.

Metallurgy and Metallography B3–21. Fatigue of Materials. The joint investigation on the fatigue of materials under the direction of Prof. H. F. Moore is progressing at the University of Illinois. Already many tests have been run, and although no conclusions can be definitely drawn from the results at present, certain indications have been obtained. Address Prof. H. F. Moore, University of Illinois, Urbana, Ill.

Metallurgy and Metallography B4–21. Substitute Deoxidizers. The manufacture and testing of new deoxidizing alloys described in a paper by J. R. Cain for the Division of Engineering of the National Research Council is in progress. Five of the alloys have been made at the Bureau of Standards and five other by the Metal & Thermit Corporation, while the Fitzgerald Laboratories are to make others. The lead-magnesium alloy had had a preliminary test at the Bureau of Standards for deoxidizing American ingot iron. All of the alloys are to be tested at the Bureau of Standards for deoxidizing efficiency. Address J. R. Cain, Bureau of Standards, Washington, D. C.

C—Research Problems

The purpose of this section of Engineering Research is to bring together persons who desire coöperation in research work or to bring together those who have problems and no equipment with those who are equipped to carry on research. It is hoped that those desiring coöperation or aid will state problems for publication in this section.

Metallurgy and Metallography C1–21. Absorption in Furnaces. An inquiry has been received by the Research Committee regarding the absorption of heat by steel. The statement was made that steel absorbs heat as the 6th power of the radiancy and that this absorption does not mean the radiation of heat by the Stefan-Boltzmann Law. The Research Committee is not able to explain this statement and would appreciate any communication with the inquirer regarding the meaning of the above statement and the reference to an authority regarding it. Address A. E. Walden, 100 West Fayette St., Baltimore, Md.

D—Research Equipment

The purpose of this section of Engineering Research is to give in concise form notes regarding the equipment of laboratories for mutual information and for the purpose of informing the profession of the equipment in various laboratories so that persons desiring special investigations may know where such work may be done.

Victor J. Azbe, D1–21. Power-Plant Laboratory. Laboratory equipped with apparatus for chemical analysis and physical tests concerning power-plant economy. Fuels of all kinds, solid, liquid and gaseous, are handled. Apparatus for making determinations of the fusing point of ash, for water testing and analysis of boiler scale are included. General industrial work is to be cared for by the laboratory. Address Victor J. Azbe, 2194 Railway Exchange, St. Louis, Mo.

Scovill Manufacturing Company, D1–21. The Scovill Manufacturing Company, of Waterbury, Conn., has a separate building 213 ft. long, 50 ft. wide and 20 ft. high devoted to research work and control work for its product. The building is subdivided into offices, library and rooms for metallography, electric-furnace work, photography, polishing, weighing, physical testing and a main laboratory for routine work in analysis of brass, bronze, nickel, silver, cupronickel, steel, copper, spelter, special alloys and oils and greases. During the war there were 94 people employed in the laboratory. Address Scovill Manufacturing Company, Waterbury, Conn.

E—Research Personnel

The purpose of this section of Engineering Research is to give notes of a personal nature regarding the personnel of various laboratories, methods of procedure for commercial work or notes regarding the conduct of various laboratories.

Victor J. Azbe, E1–21. Mr. Azbe, who has been devoting many years to the investigation of losses in steam-power development, has realized the importance of supplementing his field work with the equipment of a research laboratory for prompt and accurate reports on materials used in power plants. For this purpose he has established a laboratory for carrying out chemical analysis and physical tests. This laboratory will be devoted to reports on materials for general industrial work. Address Victor J. Azbe, 2194 Railway Exchange St., St. Louis, Mo.

Materials of Engineering E1–21. Standard Samples. The Bureau of Standards is distributing standard samples of materials for comparison and other uses such as control analysis. During the month of November 434 samples were issued costing $849.25. Sample 23-A of Bessemer 0.8 per cent carbon steel and No. 51 electric-furnace 1.2 per cent carbon steel were issued for the first time. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

F—Bibliographies

The purpose of this section of Engineering Research is to inform the profession of bibliographies which have been prepared. In general this work is done at the expense of the Society. Extensive bibliographies require the approval of the Research Committee. All bibliographies are loaned for a period of one month only. Additional copies are available, however, for periods of two weeks to members of the A.S.M.E. or to others recommended by members of the A.S.M.E. These bibliographies are on file in the offices of the Society.

Petroleum, Asphalt and Wood Products, F1–21. Recent Articles on Petroleum. The recent articles on petroleum and allied substances are compiled each month for the Bureau of Mines by E. H. Burroughs. This bibliography includes articles on geology and the origin of petroleum, on development and production, patents, transportation, storage and distribution, properties and their determinations, refining and refineries, utilization, legislation and legal regulation, statistics, economics, organization and institutions. It also gives a list of bibliographies on this subject. Address Bureau of Mines, Washington, D. C., H. Bain Foster, Director.

Bibliographies Compiled by U.E.S. Library

The Engineering Societies Library announces the completion of bibliographies covering the subjects of Pulverized Coal and Fuel Oil for Raising Steam. The former contains 41 typewritten pages and has 283 references, each accompanied by a short explanatory note. It covers the years from 1910 to 1920. The latter, extending over the years 1911 to 1920, covers 22 typewritten pages and contains 201 references. The search is divided into five parts: (1) General; (2) coal vs. oil; (3) marine use of oil; (4) oil for locomotives and (5) apparatus and combustion.

Those desiring to purchase copies of these bibliographies should address Mr. Harrison W. Craver, Director of the Engineering Societies Library, 29 West 39th Street, New York, N. Y.

CORRESPONDENCE

Contributions to the Correspondence Department of Mechanical Engineering are solicited. Contributions particularly welcomed are discussions of papers published in this Journal, brief articles of current interest to mechanical engineers, or suggestions from members of The American Society of Mechanical Engineers as to a better conduct of A.S.M.E. affairs.

Objects to the Use of Greek Symbols

To the Editor:

I wish to make a criticism of the use of Greek letters in the columns of Mechanical Engineering.

My attention has been called to a paper in your November issue, entitled Calibration of Nozzles for Measurement of Air, etc., where repeated use is made of the symbol "psi" for an important coefficient. The objection to a Greek letter in this connection is that the language has been dropped from the educational system. Engineers do not study Greek, and probably few of them know more than three letters of the Greek alphabet.

Greek symbols are therefore unfamiliar to a majority of your readers. Their further use in your columns is hardly defensible except on grounds of tradition and precedent. No reader likes contact with a symbol which he does not know how to pronounce, and which he hesitates to write. The printer must find Greek a nuisance to set up. Those of us who use typewriters find it troublesome, because Greek is not on the keyboard.

I am aware of the fact that engineering literature is full of Greek letters and that certain symbols such as "pi," ratio of circumference to diameter, and "delta," symbol of differentiation, will survive. My plea is that in original papers, offered to engineers through your columns, the use of Greek letters be discouraged, if not definitely forbidden.

New Haven, Conn.

Books for Supplementary Reading by Students

To the Editor:

Supplementing my communication in the January number asking for suggestions of books for supplementary reading by students in industrial management, I append a list which we have used for the course at the University of Illinois.

The objects of this supplementary reading are several, namely: To broaden knowledge of the principles underlying the conduct of industrial affairs; to promote a better understanding of the human element and its relation to industry; to enlarge acquaintance with the ideals and methods of distinguished thinkers, investigators, and producers; and to develop clearer conceptions of the tasks which engineers entering the industrial world are called upon to perform.

Four books are to be read and reported from the following list:

- Principles of Management, by Taylor
- Twelve Principles of Efficiency, by Emerson
- Work, Wages, and Profits, by Gantt
- Investigating an Industry, by Kent
- Human Factor in Works Management, by Hartness
- New Industrial Day, by Redfield
- Organizing for Work, by Gantt
- Industrial Goodwill, by Commons
- Motion Study, by Gilbreth.

Books are assigned arbitrarily unless the student already has read certain volumes or when personal preference for particular authors is supported by satisfactory reasons. In the case of students who desire to do additional reading, assignments are made from a subsidiary list of books as follows:

Man to Man, by Leitch; Work and Wealth, by Hobson; Psychology and Industrial Efficiency, by Münsterberg; Time Studies and Rate Setting, by Merrick; Fatigue and Efficiency, by Goldmark; Scientific Management and Labor, by Hoxie; Turnover of Factory Labor, by Slichter; Common Sense and Labor, by Crowther; Personnel Administration, by Tead and Metcalf; Principles of Industrial Organization, by Kimball; Profit-Making Management, by Carpenter.

The reading of books relating to practical application of methods or descriptive of existing systems of management is discouraged at this time, but a complete bibliography of management is supplied and suggestions offered as to the many admirable books which should be helpful in actual practice. It is believed that during this period attention should be focused almost exclusively upon principles rather than upon the details of practice and the selection of books is made with this consideration in view.

This matter is presented here in this form to stimulate interest in the general topic of reading, not only for the younger generation of engineers, but also for all engaged in the profession. What books should be read by young men in training for careers in the industrial or engineering world? What substitutions, withdrawals, or additions in titles can be made with profit in the lists of books referred to previously? Is there a "Three-Foot Shelf of Books" for engineers? These are questions of rather large significance and in my opinion a discussion of them in the columns of Mechanical Engineering will confer direct benefits on a large section of the membership of the Society. May we not have such a discussion?

Bruce W. Benedict.

Urbana, Ill.

Extending Ocean Navigation to the Great Lakes

To the Editor:

Replying to the communication of Charles Whiting Baker on page 592 of Mechanical Engineering for October, concerning the development of the St. Lawrence River as a waterway, I wish to call your attention to some important considerations that have been neglected.

The City of Chicago, one of the most southerly of Great Lakes ports, is closed to navigation by ice for at least five months of the year. Furthermore, the other end of the proposed waterway, the mouth of the St. Lawrence River, is 625 miles north of Chicago. The region of the ocean north of Sable Island and the Banks of Newfoundland, between Cape Sable and Sable Island, in close proximity to the Strait of Belle Isle, is known to all deep-water sailors as the "Graveyard of the Atlantic." The navigation of this region is regarded by all ship owners and underwriters as the most hazardous of the entire globe, owing to the quantities of ice from the coast of Labrador, much of which is forced through the Strait of Belle Isle, involving the Gulf of St. Lawrence in an almost constant menace of snow, ice and fog to all shipping entering or departing from the Gulf and its neighboring waters. The Allan Line of English ships operates from Montreal under a heavy subsidy or contract with the British Government and every winter it is obliged to abandon its regular St. Lawrence route and port of call for some port on the coast further south.

In view of the conditions of navigation above submitted, and of the complete failure of the former attempts to overcome the difficulties, it is respectfully submitted that the theories of Charles Whiting Baker and Mr. Merrick, President of the Association of the Chamber of Commerce of the City of Chicago, together with the visions of great commercial development throughout the fourteen states in proximity to the Great Lakes, as the result of these theories, are based upon misleading and fallacious arguments, resulting from a complete lack of knowledge of conditions as already experienced, and involve the expenditure of millions of dollars in a venture which is foredoomed as a successful financial enterprise.

Garden City, N. Y. E. Platt Stratton.

Sees Danger in St. Lawrence River Project

To the Editor:

The St. Lawrence project is being discussed. This project contemplates the construction of canals, locks and dams whereby to provide a navigable water passage from the Great Lakes to the Atlantic Ocean. That this project will be of value to the United States need not be gainsaid.

It is true that the products and manufactures of the Middle West can be shipped through the lakes and St. Lawrence River and its proposed canals to the ocean for domestic and foreign ports at far less expense than they can now be shipped when they must be transferred from lake boats to rail and then, for foreign commerce, again to boats. It is true that practically all of the commerce of the Middle West would pass through this canal; and the Middle West is our great industrial center. It is said that the railroads would be injured by the diversion of freight traffic; but the railroads would make provision for this loss and their spare rolling stock, if any, would be diverted to other regions in sufficient numbers to permit the operation of the remaining equipment at full capacity.

In the St. Lawrence project, however, resides a grave danger to the economic and political welfare of the country; and this project should not be carried to completion.

The mouth of the St. Lawrence River lies entirely within the boundaries of a foreign country and is comparatively remote from the boundaries of the United States. If the project be carried out, the business of the entire Western and New England States and the political welfare of the whole country at large will be dependent upon the maintenance and continuance of friendly relations with our neighbor. While we have the greatest friendship and respect for that country and hope that serious differences will never arise between us, yet it is not without the bounds of reason, and also of experience, to anticipate serious differences; and, if ever a state of war does spring up, the mere blockade of the mouth of the St. Lawrence River will utterly cripple the entire industrial section of our country. Our railroads will immediately become so congested by the attempted diversion of the water freight to rail as to be useless by reason of the previous reduction of their rolling equipment. No one can predict, in these troublesome times, a continuance of peace. It must be remembered that the country controlling the outlet of the St. Lawrence is but one of the children of that mother country across the sea. That mother country, by virtue of possession of Gibralter at one end and the Suez Canal at the other end, governs traffic in the Mediterranean Sea; and by possession of the Dardanelles controls the economic condition of lower Russia. By diverting the traffic of the industrial section of the United States through the St. Lawrence River, that mother country would control the political and economical welfare, in time of stress, of the United States.

This project must be dropped.

Boston, Mass.

Theoretical Consideration of Bending in Shafts

To the Editor:

I have never seen any literature on the subject of bending in shafts in which any attempt is made to consider the pressure distribution of the loads and reactions and the effect various distributions might have. The following was written as the result of a problem presented to me by the engineers of an industrial firm, substantially as stated. The solution with the assumptions made is very simple, and while there may be some published work covering the subject, it has not come to my attention.

So far as the writer has been able to ascertain, the methods used in practice in the calculation of the shaft bending moments have been based on the results of experience rather than any theoretical considerations. One concern had the following method for its standard practice: The reactions were first calculated assuming that they could be considered as concentrated at the centers of the bearings. The reaction forces were then considered as uniformly distributed over areas of width equal to the diameter of the shaft such that the pressure per square inch was equal to the maximum allowable crushing strength of the bushing material. These areas were at the ends of the bearings nearest the force causing the bending and the moment arms were measured from the centers of these areas. As some of the subsequent statements show, there are cases where the general theory on which the above method of calculation is based holds true. Shafts calculated by this method did give shaft sizes which agreed more or less with the results of experience, but since there was no general justification for the theory on which it was based, it was subject to erroneous use. Another concern uses one-quarter of the length of the bearing in determining the moment arm.

The concern first mentioned has recently adopted one-third the length of the bearing as determining how much of the bearing length is to be considered in the moment arm. This adoption was based on the considerations described in following paragraphs. It was found that practically all the shafts used in their work had moment arms which included about one-third the length of the bearing so that that value was satisfactory, the variations from it being within the limits of accuracy of the computations.

The maximum bending in shafts is not only a function of the various total loads and reactions, but is also a function of the distribution of the loads and reactions along the shaft. The distribution along the shaft is practically impossible of accurate determination and is affected by several factors. The flexibility of the shaft, the lack of absolute rigidity of the bearing supports, the quality of the lubrication, oil pressure, friction, and wear of the shaft and bushing, all affect the pressure distribution.

There is a tendency of the shaft to bend in the direction in which the force acts which would cause the shaft to bear only at one end of the bushing. The bearing supports also possess some flexibility and they tend to conform in position with the deflected shaft. All bearings in which the shaft revolves are lubricated and the oil film, unless completely broken, tends to equalize the pressure distribution. The friction in the bearing does not tend to vary the pressure along the shaft as it does in a circumferential direction. Wear and flow of the bushing material are undoubtedly the most important factors in determining the pressure distribution along the bearing.

With a new bearing, the pressure at one end of the bearing will unquestionably be higher than at the other due to the deflection of the shaft. The higher pressure, will however, cause greater flow of the bushing material or greater wear at the points of lesser pressure so that the tendency is to produce or at least approach a uniform distribution of pressure along the shaft. This is particularly true in case the loading is not varying greatly. In the case of intermittent shock or impact loading it is doubtful if the bearing would wear to conform with the extra deflection of the shaft due to the extra intermittent loading, but it would probably do so if the shocks occurred with sufficient frequency.

The length of the bearing would also be a factor to consider, since, if it were sufficiently long, the time required to wear the bearing down might be more than or at least a good part of the life of the machine, so that the number of repetitions of stress at somewhere near the maximum value calculated would be relatively small, making the shaft safer than was necessary. Then, too, the deflection of the shaft would probably be sufficient to cause an opposite reaction at the other end of the long bearing which would also tend to decrease the bending in the shaft. Bearings with lengths less than twice the diameter of the shaft would not be considered as long bearings, and since practically all bearings are within this limit except for other reasons than pressure, velocity, and heat dissipation, they may be neglected in any further considerations. The other considerations seem to point to a practically uniform distribution of bearing pressure along the shaft and it is assumed to be uniform in the following considerations. This assumption makes the problem a very simple one.

First, consider a shaft in which the load causing bending is beyond the bearings as shown in the force diagram, Fig. 1. If the force causing bending is F and the bearing pressure is uniformly distributed along the shaft in the bearings, the reactions may be calculated as concentrated at the centers of the bearings. If a is the distance from the force to the center of the nearest

$$R_1 = \frac{(a+c)F}{c} \text{ and } R_2 = \frac{aF}{c}$$

With uniform distribution of bearing pressure along the shaft the shear diagram is as shown in Fig. 1, in which R is the point of zero shear. R is at a distance d from the end of the bearing nearest the force F and

$$d = \frac{bF}{R_1} = \frac{bcF}{(a+c)F} = \frac{bc}{a+c}$$

The bending at any point in the shaft is equal to the area of the shear diagram either to the right or the left of the point. Since the maximum bending occurs at the point of zero shear, the maximum bending moment is

$$M = \left(a - \frac{b}{2}\right)F + \frac{bcF}{2(a+c)}$$
$$= \left(a - \frac{b}{2} + \frac{bc}{2(a+c)}\right)F$$
$$= \left[a - \frac{b}{2}\left(1 - \frac{c}{a+c}\right)F\right]$$

The actual bending-moment diagram for the shaft under consideration is shown in Fig. 1. The distance y is equal to $d/2$ and the area of the rectangle having F for one side and $a + y - b/2$ for the other is equal to the area of the shear diagram to the right or left of the point R. It will be noted that at the point of maximum bending the shear is zero, so that while designers ordinarily omit it from their computations because it is generally a relatively small factor in the shaft stress, it really is a zero factor at the point of maximum bending.

In case the force F is between the bearings, its pressure distribution along the shaft becomes the primary factor in the determination of the bending in the shaft. In case the loading of the force F along the shaft is practically uniform, the same equation just developed is applicable, only in this case a becomes the distance between R_1 and F and c the distance between R_2 and F, while b becomes the length of the load distribution along the shaft.

It is evident that except in short shafts there is not much difference in the bending moments determined by the above method and by the use of the distance to the center of the reaction as the moment arm. These considerations, however, are very important in the economy of material in short shafts.

In short shafts there are generally two forces as well as two reactions causing bending in the shaft. These forces may be external to the two bearings either on opposite ends of the shaft sure distribution on the bearings along the shaft is considered uniform, the bending-moment diagrams may be determined individually and then be combined to give the resultant bending

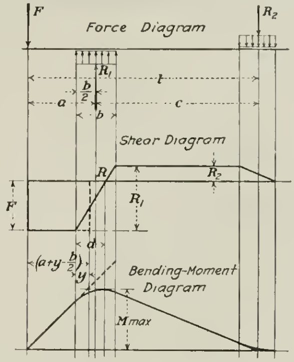

Fig. 1 Bending in Shafts

moments. The resultant points of maximum bending will probably be at some other points than the points of maximum bending for the individual forces taken alone, but will be very near them, and in the case of the two forces on opposite ends of the shaft overhanging the bearing and the case where only one force is between the bearings and the one external to the bearings is large enough to bring the maximum resultant bending in the shaft in the bearings, will not vary materially from the maximum individual moment. In the other cases, depending on the conditions of the loading, the maximum resultant bending moment may or may not differ greatly from the maximum bending moment due to one of the forces, but a trial calculation should at least be made before ignoring the other.

The foregoing method of calculation seems to offer a fairly theoretical solution which will agree quite well with practice and in some cases of design should permit of an economy of material over present methods of design. In other cases it will serve as a very good check on the safety of shafts, since any error due to the assumptions in the method is on the side of safety.

Charles W. Good.

Ann Arbor, Mich.

WORK OF THE A.S.M.E. BOILER CODE COMMITTEE

The Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York, N. Y.

Rules for the Staying of Plain Circular Furnaces

The attention of the chief boiler inspectors in the states and municipalities where the A.S.M.E. Boiler Code is effective has been called to the fact that the question of the rules for the staying of plain circular furnaces has been under consideration by the Boiler Code Committee for several months as a result of certain features that have been noted in Cases Nos. 256 and 293, in their relation to the special allowance made in Par. 212c of the Boiler Code.

A special sub-committee to the Boiler Code Committee was appointed at the October meeting of the Committee to thoroughly investigate this matter, and as a result of the discussion of the matter at the December meeting, it was decided that it would be advisable to inform them of this situation and suggest that in view of a possible revision of Par. 212c, this Rule of the Boiler Code should not be used until the Committee's investigation can be completed and reported upon.

Conference Committee on Welding

The Boiler Code Committee takes pleasure in announcing that the American Society of Refrigerating Engineers has appointed a Committee to confer with the Sub-Committee of the Boiler Code Committee on Welding. The above is the result of an invitation extended by the Council of the A.S.M.E. at the request of the Boiler Code Committee. It is the desire of the Boiler Code Committee that the Committee of the American Society of Refrigerating Engineers shall coöperate with the Sub-Committee of the Boiler Code Committee in discussing the rules now in the Code and in proposing to the Boiler Code Committee any revisions or new rules that may be embodied in the Code at the next revision period. The personnel of the Committee appointed by the American Society of Refrigerating Engineers is as follows:

Louis Doelling, *Chairman*, New York, N. Y.
E. F. Miller, Cambridge, Mass.
Fred Ophuls, New York, N. Y.
Norman M. Small, Waynesboro, Pa.
Harry Sloan, Milwaukee, Wis.

Motorships

Charles E. Lucke

European shipbuilding nations, the Scandinavians at first, but now practically all, including England, France, Holland and Italy, in addition to Germany, have for some years been building large Diesel engines and auxiliary equipment for the driving of seagoing vessels. In more recent years this movement has been accelerated by the proved economy of the equipment that has been found most reliable and the reduction in cargo-carrying costs by the motorship over the steamship. The raising of all prices and costs by the war has directed attention to every possible source of saving, and this among other things has further increased the volume of motorship building at the expense of steamship construction.

During this whole period of experimental development of the propelling machinery, and with its perfection the large-scale demonstration of lower cargo-carrying costs over competing steam equipment, America has done nothing with the motorship. On the contrary, there has been a great increase in steam cargo carriers, first as a result of war demands and later as a national movement for the reëstablishment of the American merchant marine in a position of some commanding importance at sea.

While America has been building more and more steamships, the Europeans have been building fewer in proportion, replacing them by motorships, partly on the basis of demonstrated reliability but mainly on the basis of proved reduction of operating costs. Only now have our shipping interests passed the period of consideration and entered upon that of action.

It has taken some years to convince American shipping interests that the motorship is reliable; it has taken some years to convince these same interests that America can build satisfactory engines and that they need not be reproductions of European models; but it can be said definitely that shipping interests have now reached the point of accepting this situation. It is admitted that American Diesel engines can be built equal in quality to those built in Europe and also at competing costs, but in spite of this there has not as yet been any great adoption of the motorship in this country. Only a few have been contracted for today, although a great many projects are under consideration.

Apparently American shipping interests have not yet been convinced of the superior operating economy and lower cargo-carrying costs of the motorship as compared with the steamship, especially when the latter is provided with the geared-turbine Scotch-boiler type of equipment. At the present time the future of the motorship in American shipping activities seems to be hanging in the balance of these comparative costs of operation.

The motorship equipment costs materially more to buy than does the steamship equipment. Its fuel consumption is materially less, the ratio at sea being 1 to $2^1/_2$ and still more favorable while in port. While there are corresponding differences in all of the other items of expense, such as wages and subsistence of crew, maintenance, repairs, stores, to mention a few of the leading items, it appears that the main elements of controversy and uncertainty lie in the balancing of the money saving by the motorship, due to fuel economy, against the excess of fixed charges which it must carry.

Whether or not the cheaper steamship, burning $2^1/_2$ times as much fuel as the motorship at sea, will give a lower or higher total cost of handling cargo per ton-mile, depends not only on the difference in the first costs, but also upon the prices of fuel per gallon, on the number of sea-miles per year of operation or horsepower-hours per year, or the ratio of time spent at sea to that in port; and in the case of the fuel on whether or not the motorship burns the same grade of fuel at the same price as does the steamship. For any given first-cost differential, constituting a fixed-charge handicap against the motorship, the money saving by the superior fuel economy of the motorship will be more than enough to offset it and show a net profit, provided the ship is kept at sea in actual cargo carrying a sufficiently large proportion of the total time. It will also depend on the fuel-price differential, as well as on the fuel price itself.

Analyses of these cost factors and totals indicate that the motorship is best adapted to long-distance voyages, the longer the better, and in this connection it should be noted that in the double-bottom bunkers of the motorship sufficient fuel can be carried for a total of 20,000 miles, which is much more than in the case of a steamship. The minimum length of voyage that can be profitably assigned to the motorship in competition with the steamship would seem to depend on the fuel-price differential, assuming the two ships do not burn the same grade of fuel.

As to fuel price, it seems pretty clear from what statistics are available that the general trend of price is upward, and that in view of the growth of the automotive undustry this will continue so. This being the case, so far as forecasts are at all justified, it would seem fair to predict that, if anything, conditions in the future will favor the motorship more than in the past, because with a given saving in fuel per ton-mile by the motorship over the steamship, the money saved will be greater the higher the price of fuel.

The matter of price differential, however, is a disturbing factor. The Diesel engine has in the past consistently used a higher grade of fuel oil than has been burned under the boilers of the steamship and at prices ranging from 25 cents to 50 cents a barrel more than the steamer bunker oil. Due to the increase in the demand for light petroleum products for motor cars and similar uses, there is almost sure to be a greater differential in price between the lighter fuel that the motorship has been using and the low-grade steamer bunker oil than has been the case in the past. This would be serious, and the saving in the motorship would be wiped out if the differential were great enough, provided it were true, as some think, that the Diesel engine could not burn the lower grade of oil.

As a matter of fact there is no reason to believe that the Diesel engine cannot burn this low grade of oil except that so far it has not done so. It has not done so mainly because it is necessarily more troublesome, and so far it has not been necessary to take that trouble. It is quite clear, however, that when the price differential becomes great enough, it will be worth while to go to some trouble

which will restore to the motorship all of the advantages to which it is entitled.

To adapt the motorship to the burning of the lower-grade oil, which seems to be really the only step necessary to eliminate even the residual doubts remaining in the minds of American shipping interests, there are only two factors of any importance to be studied, namely, spraying of the oil and ignition temperatures.

It appears from all of the research work that has been done on spraying, particularly in connection with the spraying of oil in boiler furnaces with the so-called mechanical atomizers, that all oils can be sprayed equally well regardless of their other physical properties if they are brought by heating to the same viscosity. It would seem as if this should also be true when the oil is sprayed into a cylinder against a pressure of from 400 to 500 lb. per sq. in., and some experimental work already done confirms this as a reasonable conclusion, though it is not yet a commercially established fact.

If the heavier residual fuel oils have, as may be the case, a higher ignition temperature than the lighter ones, there may be some difficulties about ignition at the compression which has been used for the lighter fuels. In this case two remedies are available: one to raise the compression, which has the objection of overloading the bearings, framing or the running gear and consequently increasing weights to avoid this; and the other to use an igniting fuel in small amounts, not exceeding 10 per cent of the total injected before the main supply of fuel, as has been done in Europe in burning tar oil. As soon as it appears to be necessary American engineers will undertake the building of the auxiliary apparatus and make the modifications necessary to adapt any grade of oil to the oil engine that can be fed through pumps from storage tanks, and thus wipe out any price differential that may exist, or may develop in the future, with every prospect of success. In general, whatever appliances are successful with one type of engine will be successful with all, because engine differences are not such as will prevent the general adoption of a broad scheme of fuel-oil conditioning developed for this purpose.

It may be said, therefore, that America is about to enter on its program of motorship development and use, and in fact has actually entered it within the last year. The rate of adoption depends upon the speed with which established facts become recognized and known, and are followed by building orders. It is of considerable interest to note that the motor-car industry, in which America now leads the world, developed in Europe in quite the same way as the motorship industry, and it is not too much to expect that once American interests become convinced that the motorship is what the Europeans think it is, American motorship construction and operation will also lead the world.

Charles Edward Lucke.

What Happened in Italy

The recent attempt at industrial communism in Italy is of particular interest to engineers because of its development in the metal-working industries. Light has been thrown on the sequence of events and the underlying causes by the publication in *Current History* for December (The New York Times Company) of translations of official documents bearing on the situation, which form the basis of the following summary.

The quasi-revolution which occurred was a forcible attempt on the part of the workers to overcome the dominance of capital and to secure a position where labor would be raised from the position of a commodity, with wages subject to the laws of supply and demand, to that of a participant in the management of industry.

The background for the unrest is to be found in the fact that in Italy, more than any other country, special industries had been founded, or existing industries measurably increased, to meet the demands for war material, while the amount produced had depended almost entirely on the supply of raw materials secured from abroad. Under this situation the return to normal conditions, with curtailed production, must necessarily have produced more or less of a crisis. Coupled with this were two disturbing factors: one,

Italian workman previous to the war.

Wage advances did not keep pace with the advances in the cost of living, due in part to the prohibition of emigration, and the point was reached early last fall where the Federation of Italian Metal Workers made a demand for a 50 per cent increase in wages, which was promptly denied by the employers. Immediately a "stay-in" strike resulted, the men remaining in the factories and drawing their pay, but doing as little work as possible and reducing output by as much as 50 per cent. The employers then decided to close their plants and issued a lockout order. The workers retaliated by taking forcible possession of the factories and within a few days practically all the engineering and metallurgical plants in Italy were under control of the workers, a declaration being issued by the Federation to this effect on September 3.

The Government tried to effect a settlement, but the employers refused its proposals and the Government then made it plain that it would not use force to eject the workers from the factories, as this could not be done without bloodshed. Two days later the Employers' Federation passed a resolution demanding the evacuation of the factories as a condition for resuming negotiations and resolutions were framed upbraiding the Government for its "pretense of neutrality" and "its hesitation, not only to defend law and order, but to maintain the position of the state as a superior body or force, representative of the national interest, armed both with the will and capacity to guarantee the security of civil and of social life."

On September 12 an important conference of the workers of Milan decided to hand over to the General Federation of Labor the direction of the movement and the matter was put before the Government by the workers, calling for a modification in the relations which previously obtained between employers and employees. The gist of their statement is embodied in the following quotation:

> Such modification should tend to permit the latter (the workers), through the agency of their trade unions, to be in a position to know the real state of their industry, to be acquainted with its technical and financial workings, and to be able, through the work of their factory delegations (being offshoots of the trade unions) to coöperate in applying factory regulations, to control the appointment and dismissal of the employees, and thus to inspire the normal life of the factory with the necessary discipline.

The prime minister, Signor Giolitti, now intervened and what amounted to an ultimatum was presented to the employers calling upon them to accept the principle of the workers' demand for "controllo," this word being generally interpreted to mean participation or coöperation in factory management rather than absolute control, as has sometimes been assumed.

On September 16, the General Federation of Italian Employers submitted to this demand in a statement containing the following:

> It consents, provided that the other side be truly inspired by a like intention, to accept the principle of a control of industry to be carried out on the basis of legislative regulations, granted that such regulations do not establish any monopoly or superiority of the trade-union organizations, lay down the principle of the coöperation and joint responsibility of the various factors of production, be carried out to the advantage of the community, and abstain from interfering in the freedom of movement necessary to industrial undertakings.

The Government finally issued a degree calling for a commission of an equal number of members from each side to formulate suggestions for solving any questions that might arise in the application of factory rules and the appointment and dismissal of workers; calling upon workers of all classes to resume their employment.

It cannot now be predicted whether, as one writer has said, this "revolution" was only a "dress rehearsal" for a worse one to follow, or whether stability has probably been attained. An excellent summation of the situation as it now appears, however, has been given in the *Engineering Review* (London) for December, by Andrew Stewart, of the Consolidated Pneumatic Tool Company, Ltd., from which the following extracts are taken:

> What terminated the revolutionary experiment was the discovery that there was no money to pay wages at the end of the week, nor was there any money to purchase raw materials. Sellers of materials were not prepared to do business with people who apparently could not pay. A few managed to carry on for a week or two by selling what they could and applying the proceeds to pay wages, but it was soon found that the value of

the product was insufficient for the purpose; in other words, the business quickly became insolvent.

They also found that they had to face problems of policy and administration, which they were incapable of solving; in short, they had taken over a great commercial machine which they could not run. In their anxiety to secure all the supposed products of their labor, they discovered that they could not even produce sufficient to pay the worker his normal wage, while the capitalist could do so, and even get something for himself. The capitalist could work the machine; they could not; and the "profits" accruing from the workers' control were a will-o'-the-wisp.

One of the outstanding features of the "revolution" is that, while it has fizzled out, it has achieved some notable results. It has demonstrated that an intelligent and well-informed democracy is poor material for the revolutionary. A less intelligent democracy would have plunged Italy into an abyss of misery far beyond the worst that has ever occurred in Russia, for it is obvious that, while in an agrarian district a revolutionary change has an imperceptible immediate effect, since stocks of food and necessities generally are sufficient for a long period, in an industrial district the necessities of the workers can be met only by an immediate exchange of the products of industry for the necessaries of life, and anything which interferes with the flow of industrial products from the producer, or the return flow of food and other manufactured articles to the producer, must have an immediate and disastrous effect on the worker.

Fuel Efficiencies From a National Standpoint

There are several methods for determining the relative efficiency of fuels. This may be on the basis of the number of B.t.u's usefully obtained per pound of fuel; or the number of B.t.u's usefully obtained from one dollar's worth of fuel at the plant; or, again, the number of B.t.u's usefully obtained for each dollar of expenditure in connection with the fuel. The latter includes not only the cost of the fuel itself delivered at the plant, but all the direct and indirect items involved in handling the fuel up to the moment where it generates power, and possibly even afterward.

These methods of fuel appraisal are all on the B.t.u. basis and are concerned only with the individual conditions of the particular plant considered. There is a growing realization, however, that heat-unit efficiency is only one of the many items to be considered, and that a broader view, on a national basis, with due regard to fuel conservation and the interests of the public, must be taken.

If a concern burns, say, 500 tons of coal daily, this means, roughly, ten gondola cars a day. These cars have to be hauled from the mine, possibly over a badly congested section of railroad. Delay and increased expenditure are thus created in the transportation of other freight vitally needed both by the purchasers of the coal and by other concerns in the same industrial district.

From a national point of view it would be well to consider whether it would not result in better overall efficiency if the concern in question were to use its fuel in some form which could be transported in such a way as not to interfere with the shipment of other freight.

From a national point of view, again, the consideration now being given to the utilization of coal at the mouth of the mine and the transportation of the fuel in the form of electric current to points where it is to be used, is of pressing importance. Electric current, however, cannot as yet be efficiently used for heating, of which modern industry requires a large amount; and in the generation at the mouth of the mine in the immense plants which would be required there would be difficulty, in many cases, in securing an adequate supply of water for condenser operation.

In a paper presented by Sir Arthur Duckham before a meeting of the Institution of Petroleum Technologists, held in London last October, the author advocates another solution of the problem—the development of a process for converting coal at the mine into gas and oil fuel. He feels assured that this dual end can be attained by the adoption of the vertical-retort system of gas making, combined with an appropriate water-gas plant. The basic idea is to utilize the heat in the coke through formation of water gas by passing steam through the hot coke. "During the war," he states, "it was possible to put these ideas into practice and in continuous-working vertical retorts it became possible with steaming to obtain over 20,000 cu. ft. of very serviceable gas per ton of coal instead of the 12,000 that used to be obtained previous to the war. It was further found that with the water gas ascending the retort, the hydrocarbons generated were protected from the coal and so gave a further amuont of gas and lighter tar oils."

The scheme advocated by Sir Arthur Duckham, although somewhat different in method and intent, is in accord with the suggestion of Prof. R. H. Fernald in the December number of Mechanical Engineering, that an intensive study be made of low-temperature distillation processes to determine whether a combination of low-temperature distillation and the manufacture of by-product producer gas can be made a commercial success and constitute a solution of the natural-gas problem which this country now faces.

This whole subject is yet in a very undeveloped state. It is one that is bound to receive increasing attention and study and that may ultimately have an important bearing on fuel conservation as well as on the efficiency of plant operation, considered in their broader aspects from a national standpoint.

Utilization of Tidal Power

A great deal of attention has recently been given in England to the possibility of utilizing tidal power on a large scale. The British Ministry of Transport has conceived a grandiose scheme for the utilization of half a million horsepower from the tidal movements in the estuary of the river Severn, which empties into the Bristol channel at the junction of the Lower Avon, west of Bristol. The proposal, as stated in an interim report of the Water Power Resources of the Board of Trade, abstracted elsewhere in this issue, and as described in *The Engineer*, for December 3, 1920, is to construct a dam across the river where it is some 2½ miles wide, with a barrage, in portions of which are to be installed turbines and generators of a capacity in excess of one million continuous horsepower. About half that amount of power is to be available for distribution, the surplus energy being employed to pump water into a high-level reservoir placed at a short distance up the river. When by reason of the rise of tide in the Severn estuary below the dam it is no longer possible to work the turbines in the dam, water is to be allowed to flow from the reservoir through other turbines, thus producing a constant supply of half a million horsepower.

It follows, therefore, that for the full operation of the scheme there will have to be two gigantic hydroelectric stations, one of them, that in the dam, capable of generating upward of one million horsepower and the other, that in connection with the high-level reservoir, capable of producing over half a million horsepower. For portions of each day one or other of the two stations will be entirely inoperative, though for part of the time they would be working in parallel. The periods of working of the two stations would, of course, vary considerably because of the seasonal variations in the tides.

A striking feature of the proposal is that the water is to be forced into the high-level reservoir through a tunnel driven through more than a mile of solid rock. The tunnel is to be 40 ft. in diameter; that is, it will have nearly four times the cross-sectional area of an ordinary double-line railway tunnel.

Published statements about the cost of the development are very much at variance, ranging between $40,000,000 and $150,000,000; but it is claimed in the official report that even at the higher figure the project would be on a sound economic basis and would be a "paying proposition," not only effecting a saving in coal consumption of from three to four million tons per year, but allowing electricity current to be sold at a small fraction of present rates.

Professional Sections of the A.S.M.E.

Ten years ago the Committee on Meetings of the A.S.M.E. arranged for the formation of a number of sub-committees of specialists in different branches to secure papers and arrange for sessions in the special subjects in which they were interested. These sub-committees were instituted largely through the foresight of Dr. Charles E. Lucke, then a member of the Committee, with the underlying thought that the solution of problems worked out in one branch of engineering is often applicable and always

engineering practice.

How well these ideas have worked out can be shown by reference to the sessions of a single sub-committee—that on Textiles, which has been conducted under the able chairmanship of Charles T. Plunkett, president of the Berkshire Cotton Manufacturing Company, Adams, Mass., and the secretaryship of the late E. W. Thomas, who was agent of the Boott Mills, Lowell, Mass. While the sessions of this sub-committee have been conducted in the interests of the textile industry, but few of the papers have dealt specifically with the production of textiles. Rather have they treated of the broader problems met with in the industry, of interest as well to those in other fields. Subjects have been treated such as the principles of valuing property, specifications for factory timbers, higher steam pressures, heating by forced circulation of hot water, heat transmission through various types of sash, sawtooth roof construction, industrial power problems, etc.

The success of the sessions sponsored by the various sub-committees, and the evident interest in the special subjects treated, finally led to the formation of Professional Sections which, beginning with the last Annual Meeting of the Society, took the place of the former sub-committees. Already eight such Sections have been formed, in most of which large numbers of members have designated their desire to become associated. In the Management Section, for example, there are 1230, in the Machine Shop 727, Fuel 614, Materials Handling 676, Power 1151, and Railroads 467.

A pleasing development in this Sections movement has been the formation of the Forest Products Section, which held a most interesting session at the Annual Meeting, an account of which appears in this number. This is the initial movement for special attention on the part of the engineers to the problems of the woodworking industry, and the diversity and character of the papers presented indicate the breadth and scope of this branch of industry, starting with the felling of the timber in the forest, and continuing with its transportation to the mill and its transformation into lumber or into the more finished products with which we are all familiar, ranging from furniture to matches. It is not unlikely that many of the problems in other branches of engineering will be found to have a direct bearing on those in the woodworking industry, and that, on the other hand, the ingenuity and skill which have so long been displayed by the inventive minds among the woodworking fraternity will prove enlightening to those in the more strictly engineering fields.

Bill Introduced in Senate to Make Metric System Only Legal Standard

A stringent bill "to fix the metric system of weights and measures as a single standard for weights and measures," and which goes to the extent even of curtailing personal liberties, was introduced in the Senate on December 16, 1920. Certain of its provisions are that from and after 10 years no one shall sell goods, charge for transportation of goods, or pay for work or labor, where weights and measures are involved, except by the metric system; and that after that time no one "shall use or attempt to use....any other system." Also, that from and after four years no one shall "manufacture or make for himself for use or purchase for use any weight or measure or weighing device....in any other system than the metric."

University of Illinois to Appoint Research Graduate Assistants

The University of Illinois now maintains 16 research graduate assistantships in the Engineering Experiment Station of that University, two of which have recently been established by the Illinois Gas Association, for investigation in the field of gas engineering. There will be 15 appointments to these assistantships this in engineering, physics or applied chemistry. These appointments must be accepted for two consecutive collegiate years, and for the successful accomplishment of the required work the degree of Master of Science is conferred. Nominations to these positions are made from applications received by the Director of the Station, Dean C. R. Richards, not later than March 10. Full information as to the form of application, funds available, etc., will be supplied upon application to the Director.

Frank Harvey Ball

In the death of Frank H. Ball in Detroit on November 12, 1920, the mechanical and engineering world lost one of its most active members, as practically all of his life was devoted to the invention and manufacture of useful mechanical devices.

Mr. Ball was born on May 21, 1847, in Oberlin, Ohio, and was educated in the grammar and high schools of Buffalo, N. Y. After some early experiences in a country sawmill on his father's farm he entered into the production of steam engines for drilling and operating oil wells. He brought out the well-known Ball automatic high-speed engine and founded the Ball Engine Co., of Erie, Pa., of which he was general manager from 1880 to 1890. He then formed the Ball & Wood Co., Elizabeth, N. J., acting as general manager of this firm until 1895, when he became general manager of the American Engine Co., Bound Brook, N. J., producing the American Ball engine.

Retiring from the steam-engine business several years ago, he and his youngest son invented and put on the market the Ball

Frank Harvey Ball

& Ball carburetor for gasoline engines. In 1913 he became manager of the carburetor department of the Penberthy Injector Co., Detroit, Mich., a position which he still held at the time of his death.

Mr. Ball was not only a successful engineer but also an enthusiastic yachtsman. From his boyhood days on the Niagara River he always owned some kind of a sailing craft and was the winner of many sailing races in Buffalo, Erie and Cleveland. For several years his sailing houseboat, the *Sommerheim*, aroused great enthusiasm and interest in Great South Bay, L. I. In Erie, his devotion to yachting resulted in the formation of the Erie Yacht Club, of which organization he was made the first and only honorary member.

Mr. Ball became a member of the Society in 1883. He was one of its managers from 1888 to 1891 and from 1894 to 1896 a vice-president. He also belonged to the Society of Automotive Engineers, in which organization he took an active interest.

NEW HONORARY MEMBERS OF THE A.S.M.E.

At the Annual Meeting of The American Society of Mechanical Engineers held in New York last December, honorary memberships in the Society were conferred upon six distinguished engineers, three of whom are residents of European countries, the Honorable Sir Charles Algernon Parsons, of London, England, Lord William Weir, of Glasgow, Scotland, and Grande Ufficiale Ingegnere Pio Perrone, of Genoa, Italy. Brief sketches of the achievements of these honorary members follow.

Captain Robert Woolston Hunt

A full biographical sketch of Captain Hunt was published in the January 1919 issue of Mechanical Engineering, on the occasion of his eightieth birthday anniversary celebration. Captain Hunt, now head of the Robert W. Hunt and Company, consulting engineers, of Chicago, was for many years connected with the Cambria Iron Company and the Troy Steel and Iron Company, during which time he assisted in many notable developments in the iron and steel industry.

Captain Hunt has been a member of this Society since 1880. He was president in 1891. He is also a member of the American Institute of Mining and Metallurgical Engineers, the American Society of Civil Engineers, the Institution of Civil Engineers, the Institution of Mechanical Engineers, the Iron and Steel Institute of England, the American Society for Testing Materials, and other societies. He was awarded the John Fritz Medal in 1912 "for his contributions to the early development of the Bessemer process."

Dr. Samuel M. Vauclain

Doctor Vauclain is senior vice-president of the Baldwin Locomotive Works of Philadelphia. He has been with this company since 1883, first in charge of all buildings and equipment of the entire works, methods of manufacture and devising of special tools and machinery, and later in full charge of the plant, including manufacturing.

During the war he was special officer of the United States Government, supervising the manufacture and production of heavy ordnance. In 1917 he was appointed chairman of the Cars Committee and the coöperative Committee on Locomotives of the Council of National Defense.

The University of Pennsylvania conferred upon him the honorary degree of Doctor of Science in 1906, and he received awards from the Paris Exposition in 1900, from the Buffalo Exposition in 1901, from the St. Louis Exposition in 1904, and from the Seattle Exposition in 1908. He has been a member of the A.S.M.E. since 1894 and was vice-president from 1904 to 1906. He is also a member of the Institution of Civil Engineers of Great Britain, the American Society of Civil Engineers, the American Institute of Mining and Metallurigcal Engineers, the American Railway Engineering Association, the American Philosophical Society, and other organizations.

Rear-Admiral Robert Stanislaus Griffin

Rear-Admiral Griffin, Washington, D. C., was Engineer-in-Chief of the Bureau of Steam Engineering, which during the war covered all steam and internal-combustion engines for the Navy, took care of the upkeep of 2000 vessels, and furnished protection for vessels by the construction of emergency submarine destroyers.

The notable achievements of the Bureau during the war were largely due to the efficiency and influence of Admiral Griffin. By using electric welding in the repair of about fifty German merchant vessels seized by our Government, he made it possible, in five months, to transport to France nearly 600,000 troops. The Bnrean improved the wiring for gun-fire control systems on all installed communication systems for the service of the guns on transports and ships carrying armed guards and provided recognition signals on all vessels operated by the Navy.

Other achievements of far-reaching importance were securing control of the wire output of this country, the perfection of the submarine detector, and the installation of numerons radio equipments on vessels and at coastal stations.

Honorable Sir Charles Algernon Parsons

The commercial development of the steam turbine and its application to useful purposes on a comparatively large scale, one of the distinct achievements in steam engineering during the latter part of the nineteenth century, has become inseparably associated with the name of Charles Algernon Parsons, of London.

In 1884 Sir Charles became a partner in the firms of Messrs. Clarke, Chapman, Parsons and Company. The electrical industry at that time being the latest development of engineering, he conceived the idea that a high-speed, direct-coupled engine was required to drive the dynamo and that the steam turbine was the engine to do it.

His inventions include non-skid chains for automobile tires; an auxetophone in 1898; and the compound turbine known by his name, introduced about 1884, improved by a condenser in 1891, and adapted for maritime use on the *Turbinia* in 1897. About 1910 he invented a geared turbine.

He is the author of many publications and monographs on the steam turbine. He is a member of the Institution of Civil Engineers of Great Britain, the Institution of Mechanical Engineers, and of nnmerous other scientific and engineering societies.

Lord William Weir

Among the many engineers who did splendid service during the war, none served better than Sir William Weir, of Glasgow, Scotland, late British Director-General of Aircraft Production. As a member of the firm of Messrs. G. and J. Weir, Ltd., Glasgow, he took an active part in the manufacture of munitions immediately after the opening of hostilities, not only by helping to extend greatly the operations of his own company, but also by taking a leading share in the organization of the West of Scotland area for war purposes. His energy and his genius for work of this kind were recognized early, and in 1915 he was asked by Mr. Lloyd George to join the Ministry of Munitions, and later to undertake the duties of Director of Munitions in Scotland. Later still he was transferred from Glasgow to London and appointed Controller of Aeronautical Supplies to the Army and Navy. Afterward he was made a member of the Air Board; in December 1917, he was appointed Director-General of Aircraft Production in the Ministry of Munitions, and in January 1918 he was made a member of the newly established Air Council. He was knighted early in 1917 as a recognition of the value of his services to the nation. He is a native-born and home-trained Glasgow man, has had a wide experience of engineering practice and problems, and is an enthusiast in original research and in designing, and an organizer of outstanding ability.

Lord Weir is a vice-president of the Institution of Mechanical Engineers and a member of the Institution of Civil Engineers. He was president of the Institution of Marine Engineers for the year 1920.

Grande Ufficiale Ingegnere Pio Perrone

Signor Perrone is president of Ansaldo and Company of Genoa, Italy, which firm prior to the war was engaged in shipbuilding, making of turbines, construction of locomotives and building of electric machinery.

At the beginning of the war the firm offered to turn over its establishment to the Italian government for making large guns. The offer was not accepted but it went ahead and made guns after the best French designs, and, without a single order from the Italian government, completed two thousand pieces. After the Caporetto disaster Italy turned to the Ansaldo organization for guns, and its pieces were placed in the field at once and performed a feat which stopped the advance of the Austrians.

The firm grew to employ one hundred thousand men and women, and in the last two years of the war it bought in America and shipped to Italy in its own steamers war material which cost about fifty million dollars. It supplied ten thousand cannon, three thousand aeroplanes, many millions of projectiles and several scores of warships, torpedo boats and submarines for the use of the Italian army and navy.

AN ANALYSIS OF MACHINED FITS

(*Continued from page 133*)

The two remaining sketches, Figs. 11 and 12, show combinations which occur frequently in machine design.

Question 21. Will you kindly give your practice in such cases?

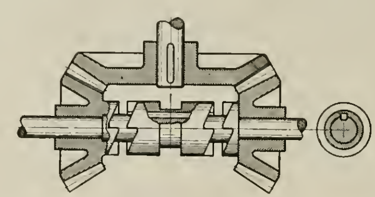

Fig. 11

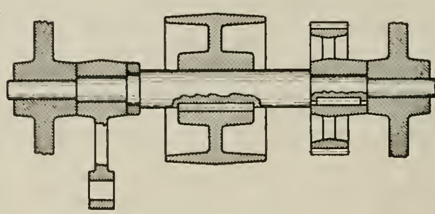

Fig. 12

Please bear in mind that the Committee has no desire that its report shall impose arbitrary standards in any case. Its first work consists in securing data as to the best present practice in this country, with the sole aim of aiding interchangeable manufacture in every way possible. Your coöperation will aid greatly in reducing manufactu ing costs in many places and in improving our already high standards of manufacture.

Last Meeting of Engineering Council—Work of Various Committees and Departments Taken Over by American Engineering Council—Classification and Compensation of Engineers—National Public Works Department Association

ON January 1, 1921, Engineering Council, which was established in 1917 by the United Engineering Society to provide coöperation between engineering societies for the consideration of questions of general interest to engineers and their relations to the public, and to provide a means for united action upon questions of common concern to engineers, merged into American Engineering Council, the executive body of The Federated American Engineering Societies. The transition brings to American Engineering Council the experience and knowledge gained by the Engineering Council and its various departments, as well as many of the individuals who have carried on the work of the Engineering Council.

The final meeting of Engineering Council was held in Washington on December 16, 1920. The morning session was devoted almost entirely to the closing of the affairs of the Council. Unfinished business and incompleted projects were referred to the United Engineering Society with the suggestion that they be laid before the new American Engineering Council with favorable recommendations.

The principal action of a continuing nature taken by the Council was the adoption of the resolution to the effect that the present financial stringency and the prospect that Federal revenues during the next year will not equal the Government expenses, make it a matter of good citizenship for every considerate person to avoid advocating expansion of Government activities; that in consequence of this belief, Engineering Council would endeavor to set the example by withdrawing its previously enlisted support of efforts to secure increased appropriations for certain Government engineering projects.

A committee consisting of Philip N. Moore, J. Parke Channing and Alfred D. Flinn was appointed to prepare a final report of the Council which would be also a history of its activities.

During the afternoon calls were paid to the chiefs of technical bureaus of the Government, the Chief of Engineers, U. S. Army, Chief of Yards and Docks of the Navy Department, Director of U. S. Reclamation Service, Director of U. S. Geological Survey, and Director of the Bureau of Mines.

In the evening the hosts of the afternoon and a number of the members of the new American Engineering Council were guests at a farewell dinner of the Council. Tokens of esteem were presented to J. Parke Channing, chairman of the Council for three years, who was largely responsible for the Washington office of the Council and the movement for a National Public Works Department, to the Secretary, Alfred D. Flinn, and also to M. O. Leighton, the Washington representative of the Council as well as chairman of the National Public Works Department Association.

Important Committees of American Engineering Council

A number of the important committees and departments of Engineering Council have been requested to continue their work, acting as committees of American Engineering Council. Brief notes are here given on some of these and on other new committees appointed, and fuller notes on the Committee on Classification and Compensation of Engineers and the National Public Works Department Association.

The Patents Committee, of which E. J. Prindle is chairman, will continue to work for an increase in both the pay and personnel of the United States Patent Office, as provided for in the Nolan Bill. The Washington office of Engineering Council has taken over by the new Council and will serve the member-societies of the F.A.E.S. as this office has in the past served the member-societies of the United Engineering Society. A. C. Oliphant as acting assistant secretary is in charge.

The Engineering Societies Employment Bureau, with Walter V. Brown retained as manager, will be continued by American Engineering Council. Until such time as a more comprehensive plan can be formulated, the secretaries of the American Institute of Mining and Metallurgical Engineers, The American Society of Mechanical Engineers, and the American Institute of Electrical Engineers will act as managers of this department. Applicants for employment will be divided into two classes, preferred and ordinary, the preferred applicants being those who are members of constituent societies of American Engineering Council, and the ordinary applicants all others.

J. Parke Channing, formerly chairman of Engineering Council, becomes chairman of the Committee on Public Affairs of American Engineering Council. This committee will handle the governmental activities of the F.A.E.S.

The elimination of waste in industry will be one of the chief tasks of American Engineering Council. A committee has been appointed to investigate this important phase of industrial development.

Colonel William Barclay Parsons is chairman of a Committee on Military Affairs, and also a Committee on New York State Government Reorganization. D. L. Hough heads a Russian-American Committee, the aim of which will be to bring the engineers of the United States and Russia closer together.

Classification and Compensation of Engineers

One of the most important of the committees whose work will be carried on by the American Engineering Council is the Committee on the Classification and Compensation of Engineers. A final report recently submitted by the chairman of the committee, Arthur S. Tuttle, and the secretary, Charles Whiting Baker, reviews briefly the activities of the committee since the time of its organization in April 1919.

The first stage of its work was completed in December 1919, at which time a report of the work accomplished was presented to Engineering Council, together with recommendations as to he adoption of a classification of engineers in governmental and railroad services and a tentative plan for compensation and promotion. An abstract of this report was published in the February 1920 issue of Mechanical Engineering.

During the year 1920 a campaign was inaugurated on behalf of the classification which had been adopted by Engineering Council with a view toward securing its general adoption and recognition as a standard for all branches of engineering service. A canvass was made of over 600 societies, associations and individuals and an analysis of the replies received shows that the endorsement of the classification is practically unanimous. The classification has actually been put into effect in a number of instances and the salary schedule has generally been endorsed.

Although the Committee has no method of measuring the results of the publicity work it has done nor the extent to which its recommendations have been followed by industrial concerns and engineering corporations, it is of the belief that more and better results have been produced than the returns at hand indicate. The Committee pointed out the need of a further publicity program to educate legislators and the general public as to the importance of the services of the engineer and also to establish personal contact with representative engineers in various parts of the country, impressing on each individual and also upon the various engineering societies the necessity of coöperation in the movement.

The final recommendations of the Committee deal with the following matters:

1 Provision for the immediate increase in compensation of the engineering staffs of the Federal Government

2 Conference with a committee of American Railway Engineering Association for the purpose of bringing about the acceptance of a common standard for the classification of engineers
3 Investigation to determine the relation between engineering charges and the cost of work supervised.

These matters have been the subject for special studies and reports during the year.

The American Engineering Council has already appointed a Committee on the Classification and Compensation of Engineers with Mr. Tuttle as chairman.

National Public Works Department Association

American Engineering Council, which voted on December 17, 1920, to take over the activities of Engineering Council, will continue the campaign to reorganize the Department of the Interior by the establishment of a National Department of Public Works. This campaign has been conducted by the National Public Works Department Association which was organized in April 1919 under the auspices of Engineering Council.

The work of this organization, while not completed, has reached a point where the establishment of a Department of Public Works seems practically assured, as is shown in an abstract of the report of M. O. Leighton, chairman of the Association, published in the January issue of Mechanical Engineering, p. 60, and in a similar report submitted by C. T. Chenery, secretary of the Association. "This was the first successful effort of the engineering profession," stated Mr. Chenery, "to directly influence the national thought and national policy." He reviewed the progress of the movement and spoke in appreciation of those to whom the engineering profession is particularly indebted for their active and effective work in the campaign, many of whom will continue their services by supporting the American Engineering Council in its efforts to bring about the creation of the new department.

Engineering and Industrial Standardization

A.I.E.E. Sponsor for Rating of Electrical Machinery

The American Institute of Electrical Engineers was designated as sponsor for the rating of electrical machinery by the American Engineering Standards Committee at its meeting on December 4, 1920, and the responsibility for the work has already been officially accepted by the Institute. A sectional committee, which will include official representatives of the Electric Power Club, the National Electric Light Association, and various other interested bodies, is being formed to carry out the work.

These arrangements have been made at the request of the electrical industry, in order to prepare as quickly as possible for the next meeting of the Rating Committee of the International Electrotechnical Commission, at which questions of great importance to the industry, including the fundamental basis of rating, will be taken up. At the last meeting of the Rating Committee in Brussels in March 1920 the American delegates presented a proposal for a system of rating based upon the hot-spot principle, which was tentatively adopted by the Rating Committee and published as a recommendation to the various national bodies composing the Commission, for official adoption by the Commission at its next meeting.

Standardization of Zinc

The American Society for Testing Materials and the American Zinc Institute have accepted joint sponsorship for the standardization of zinc under the auspices and rules of procedure of the American Engineering Standards Committee.

The Association Belge de Standardisation has suggested international standardization of the following matters pertaining to zinc: grades of commercial zinc; gage thicknesses and tolerances for sheet zinc; methods of sampling and determining moisture content of ores; and methods of analysis of ore and spelter. The American committee will work along the lines of the Belgian suggestion, but the work will not be confined to these points.

The Belgian Association has suggested similar work on the other non-ferrous metals.

Terminal Markings for Electrical Apparatus

The Electric Power Club has been designated as sponsor for the standardization of terminal markings for electrical apparatus. A sectional committee responsible for the work, and upon which all organizations interested in the subject will be officially represented, is being organized.

At the Brussels meeting of the International Electrotechnical Commission in March 1920 some of the European delegates proposed a method for marking terminals of transformers. The American delegates suggested that it would be preferable to treat the more general subject of terminal markings for electrical apparatus consistently. As a result the Americans were requested to propose a systematic plan for the whole subject.

The Electric Power Club has already done a large amount of work on the subject and has developed a general plan which is in wide use among American manufacturers. Parts of the plan, particularly the part relating to transformers, have been adopted by other organizations, including the American institute of Electrical Engineers and the National Electric Light Association.

It is hoped to secure agreement of all interested bodies on a general plan for representation at the next meeting of the International Electrotechnical Commission.

Correlation of Standardization Work in the Mining Industry

At an informal conference, held in Chicago on August 30, 1920, of representatives of leading organizations interested in the standardization of mining equipment and practice, it was unanimously voted to recommend to the American Engineering Standards Committee that there should be organized a General Correlating Committee for Mining Standardization; that this committee should be made up of representatives of organizations which are now engaged in standardization work, or which might be expected to engage in it; and that the committee might well be started with a nucleus of two representatives of each of the leading national organizations interested in the subject. In compliance with this recommendation the American Engineering Standards Committee invited the five organizations mentioned below to designate two members each to represent them upon such a General Correlating Committee, with the understanding that the nucleus so formed might enlarge itself. These representatives are as follows:

1 American Institute of Mining and Metallurgical Engineers: Graham Bright, Howard N. Evanson
2 American Mining Congress: Chas. A. Mitke, Warren R. Roberts
3 Mining and Metallurgical Society of America: E. S. Berry, B. Britton Gottsberger
4 National Safety Council: F. P. Sinn, S. J. Williams
5 U. S. Bureau of Mines: E. A. Holbrook, O. P. Hood.

The Committee has held one meeting. Summaries are being prepared of the standardization work now in progress in the various organizations. The work of the committee will include such matters as (1) delimiting specific projects which might be most advantageously handled as units; (2) recommending the order in which the various projects should be taken up in order that the needs of the industry should be served best; and (3) making recommendations as to what bodies should act as sponsors for specific projects, and as to what bodies should be represented upon the sectional committees for such projects.

Aircraft and Automobile Materials of Construction. Vol. 1. Ferrous Materials. By Arthur W. Judge. Sir Isaac Pitman & Sons, Ltd., London and New York, 1920. Cloth, 6 × 9 in., 755 pp., illus., charts, tables, diagrams, $9.

This book has been written for the user of the ferrous materials employed in the construction of automobiles and aircraft and in general mechanical construction. It is therefore not concerned with the metallurgical processes to which these materials may have been previously subjected, but with their composition, strength and properties as received from the steel manufacturer, and with modes of heat and other treatment. The work covers a wide range, and is intended as a reference work for designers and builders of machines.

Application of Dyestuffs to Textiles, Paper, Leather and Other Materials. By J. Merritt Matthews. John Wiley & Sons, Inc., New York, 1920. Cloth, 6 × 9 in., 784 pp., illus., tables, $10.

The present volume is an outgrowth of the author's earlier work, Laboratory Manual of Dyeing and Textile Chemistry, but has been broadened in scope to appeal to the interest, not only of students, but of all those concerned in the application of dyestuffs. The author has endeavored to incorporate the latest knowledge of the subject. Contains an eighteen-page bibliography.

Applied Naval Architecture. By W. J. Lovett. Longmans, Green & Co., New York, 1920. Cloth, 6 × 9 in., 664 pp., charts, tables, diagrams, $12.

The present work is a specialized treatise on the design and construction of moderate-speed merchant vessels, 350 ft. and upward in length. As naval architecture is not an exact science, absolutely accurate solutions are not necessary in many cases, and for these the author has given special attention to approximate methods, whereby results may be obtained rapidly.

Calcul des Organes des Machines. By J. Boulvin. Gauthier-Villars et Cie, Paris, 1921. Paper, 7 × 10 in., 524 pp., diagrams, charts.

The present work deals with the calculation of boilers, cylinders, pipe systems, rotating and reciprocating machinery, eccentrics, gearing and transmission systems. Throughout, it is concerned with the determination of their dimensions from the resistance of materials, so that the tension or deformation will not exceed the limits desired. Empirical formulas are avoided. Numerous difficult problems have been given special attention and are treated in a novel manner.

Compressed Air Plant; The Production, Transmission and Use of Compressed Air, with Special Reference to Mine Service. By Robert Peele, Fourth edition, revised and enlarged. John Wiley & Sons, Inc., New York, 1920. Cloth, 6 × 9 in., 529 pp., illus., diagrams, tables, $4.50.

This volume deals with the varied uses of compressed air in engineering, particularly in mining, tunnelling, quarrying and other work involving rock excavation. A chapter on the measurement of air consumption has been added to this edition, and also information on air-lift work. Typographical errors have also been corrected.

Detail Design of Marine Screw Propellers. By Douglas H. Jackson. Sir Isaac Pitman & Sons, Ltd., London and New York, 1920. Cloth, 6 × 9 in., 104 pp., tables, charts, diagrams, $2.50.

The author feels that many works on screw-propeller design carry theoretical considerations too far for the average designer. He therefore here presents, in small compass, an outline of the accepted theories, a full treatment of the practical application of them, and a short description of the various manufacturing methods. A chapter on repair work is also included.

A Dictionary of Chemical Terms. By James F. Couch. D. Van Nostrand Co., New York, 1920. Cloth, 5 × 7 in., 208 pp., $2.50.

This volume is designed to serve the convenience of readers of chemical literature by providing accurate definitions for the complex terminology of this science, in convenient form. The treatment of the terms lies between that of a standard dictionary of the English language and that of an encyclopedia.

Ein Neues Prinzip für Dampf- und Gasturbinen. By Konrad Baetz. Otto Spamer, Leipzig, 1920. Paper, 6 × 10 in., 80 pp., illus., diagrams.

The author states that the investigations described in this monograph have occupied his attention for twenty years, but that his inability to construct a model machine has caused him to publish this record of his work, in the hope that further investigations may be stimulated thereby. The problem under consideration is that of combining, in a single machine, the modes of action of the reciprocating steam engine and the steam turbine. This the writer accomplishes by a "cellular" turbine, whose rotating member is composed of cells, in which the steam alternately is compressed and expanded. The book gives the theoretical calculations supporting the author's theory and the results obtained by experiment.

Electric Traction and Transmission Engineering. By Samuel Sheldon and Erich Hausmann. Second edition, revised. D. Van Nostrand Co., New York, 1920. Cloth, 5 × 8 in., 319 pp., illus., diagrams, charts, $3.

This textbook attempts to present a perspective view of the design of a complete railway installation, from the cars to the power-station, to indicate the nature and sequence of the various problems entailed, and to suggest or illustrate methods for their solution. It is intended to assist students and young engineers to discriminate as to the pertinency or necessity of specific details.

Electro-Deposition of Metals. By George Langbein. Translated, with additions, by W. T. Brannt. Eighth edition, revised and enlarged. H. C. Baird & Co., Ind., New York, 1920. Cloth, 6 × 9 in., 875 pp., illus., diagrams, $7.50.

This book is intended as a reference book and practical guide on electroplating, based upon the scientific principles underlying the art, but devoid of mathematical technicalities. The present edition has been thoroughly revised and modernized, and new methods have been added wherever necessary.

Encyclopedia of Marine Appliances. Compiled by Alexander McNab, 1920. The McNab Company, Bridgeport, Conn. Cloth, 9 × 12 in., 206 pp., illus., $5.

An interesting catalog of marine appliances, made or sold by the publishers.

The Engineering Draughtsman. By E. Rowarth. E. P. Dutton and Company, New York. Cloth, 6 × 9 in., 269 pp., diagrams, tables. $5.

This book, intended for those familiar with the elementary principles of engineering drawing, is a collection of ninety-six exercises, arranged to illustrate the application of the principles in the production of working drawings. These examples show how working drawings of details are made from information obtained from general assembly drawings; how assembly drawings are made from detailed working drawings; how detailed working drawings are modified in shape and size to suit new machines. The plates cover a wide range of work and are taken from drawings of commercial machines.

Handbook of Building Construction. Editors-in-chief, George A. Hool and Nathan C. Johnson. First edition, first impression. McGraw-Hill Book Co., Inc., New York, 1920. Cloth, 6 × 9 in., 2 vols., frontispiece, illus., diagrams, tables. $10.

This has been prepared to provide the architect, engineer and builder with a reference work covering thoroughly the design and construction of the principal kinds and types of modern buildings, and their mechanical and electrical equipment. Each section is the work of a specialist, and although condensed, gives the

information usually needed for reference by the engineer in practice. The volumes are fully illustrated by diagrams and figures.

Handbook of Engineering Mathematics. By Walter E. Wynne and William Spraragen. Second edition, revised and enlarged. D. Van Nostrand Co., New York, 1920. Cloth, 4 × 7 in., 290 pp., diagrams charts and tables, cloth.

This is an endeavor to present in handy form and convenient pocket size, references to the theoretical and applied mathematics used in engineering. It contains the underlying engineering data and applications, as well as the mathematical formulas. The present edition has been enlarged by additions to the mathematical sections and tables of functions, and the physical and chemical constants have been revised.

The Handbook of Industrial Oil Engineering. By John Rome Battle. Vol. 1. Lubrication and Industrial Oil Section. J. B. Lippincott Co., Philadelphia, cop. 1920. Cloth, 5 × 8 in., 1139 pp., illus., diagrams, tables, charts. $10.

This handbook is intended to assist in the intelligent selection and use of lubricants for all purposes, and has been prepared for manufacturers, sellers and users of industrial oils. The range covered is a wide one and includes the use of oils in heat-treating steel, in foundry practice, in soap making and as insecticides, as well as for lubrication. Specific information on the use of oils in the major industries is given. The book also has a section on marketing and a selection of mathematical and engineering data.

Higher Mechanics. By Horace Lamb. University Press, Cambridge, 1920. Cloth, 6 × 9 in., 282 pp., frontispiece, diagrams. $8.

This treatise includes three-dimensional kinematics, statics and dynamics, and may be regarded as a sequel to the author's two former treatises on statics and dynamics. The author attempts to confine his attention to matters of genuine kinematical or dynamical importance, and to avoid those of purely mathematical or historical interest. The book is designed as an introduction to the subject.

The Human Motor, or the Scientific Foundation of Labour and Industry. By Jules Amar. E. P. Dutton & Co., New York, 1920. Cloth, 6 × 9 in., 485 pp., illus., charts, diagrams, $10.

This book is a study of the human body as a motor and of the conditions that govern its effectiveness. The author has collected the physiological data which govern the efficiency of human work and has also included a brief summary of the principles of mechanics. The work of Chauveau and Taylor is discussed and criticized, and the latter's system carefully examined.

Industrial Stability. Edited by Carl Kelsey. (Vol. 90 of the Annals of the American Academy of Political and Social Science) Philadelphia, 1920. Paper, 7 × 10 in., 168 pp., $1.

The thirty-four papers here brought together as contributions to current discussion of the general subject, present the views of business men, manufacturers, philosophers, social workers, attorneys and economists on one of the most pressing questions of the day. The major topics are the trend toward industrial democracy, labor representation in industrial management, collective bargaining, securing production, and industrial stability; and the individual papers are grouped accordingly.

Laboratory Manual of Testing Materials. By William Kendrick Hatt and H. H. Scofield. Second edition. McGraw-Hill Book Co., Inc., New York, 1920. Cloth, 5 × 8 in., 188 pp., tables, chart and diagrams, $1.25.

This concise manual of instructions for procedure in the usual physical tests of structural materials is the outcome of the operation of the Laboratory for Testing Materials of Purdue University. It is intended as a guide in class work and investigations and to explain the details of the methods. The present edition has been thoroughly revised in accordance with current practice.

The Manufacture of Sugar from the Cane and from the Beet. By T. H. P. Heriot. Longmans, Green and Co., New York, 1920. (Monographs on industrial chemistry.) Cloth, 6 × 9 in., 436 pp., plates, diagrams, tables, $8.50.

This is a systematic description of the manufacture of sugar, covering all the operations and elucidating the principles that underlie them. Detailed descriptions of sugar machinery are omitted, as the book is intended to give a broad but accurate view of the whole industry, rather than to cover the technical details of manufacture.

Modern Explosives. By S. I. Levy. Sir Isaac Pitman & Sons, Ltd. London and New York, 1920. (Pitman's common commodities and industries.) Cloth, 5 × 7 in., 118 pp., frontispiece, illus., $1.

Upon the basis of experience gained during the war, the author of this little book gives an account, for general readers, of the modern explosive industry. Stress is laid on the interdependence of modern industry and the necessity of viewing all research and productive activity as a whole, not only for purposes of defense, but to insure the well-being of the community.

Powdered Coal as a Fuel. By C. F. Herington. Second edition, revised and enlarged. D. Van Nostrand Co., New York, 1920. Cloth, 6 × 9 in., 340 pp., frontispiece, illus., diagrams, tables, $4.50.

In the two years that have elapsed since the first appearance of this work, the use of powdered coal has been greatly extended, and the book is therefore reissued in order to present the economies that have been effected and the various uses to which powdered coal has been applied. The processes for powdering coal, the suitable coals and the methods of using it are described in the introductory chapters. The remainder of the book gives the results obtained in various industries. A twenty-page bibliography is included.

Power Wagon Reference book, 1920. Edited by Stanley L. Phillips. The Power Wagon Publishing Co., Chicago. Cloth, 9 × 21 in., 880 pp., illus., tables, diagrams.

This volume is a combination buyers' directory, encyclopedia, and engineering handbook of motor trucks. The first section, on motor trucks, comprises lists of makers of trucks and truck parts, both gas and electric, tables of specifications, blueprints and articles on the use of trucks in various industries. Trailers, bodies and tractors are given similar treatment in succeeding sections, and these are followed by a collection of articles of a general nature. The book concludes with a classified buyers' directory.

Pumping by Compressed Air. By Edmund M. Ivens. John Wiley & Sons, Inc., New York, 1920. Cloth, 6 × 9 in., 270 pp., illus., tables, charts, diagrams, $4.

The intent of the book is to provide the student with a comprehensive theoretical study of the subject and the operating engineer with information on the economic essentials of the actual installation. The present edition has been enlarged by thirty pages of reliable operative data.

Rapid Methods for the Chemical Analysis of Special Steels, Steel-Making Alloys, Their Ores and Graphites. By Charles Morris Johnson. Third edition, revised and enlarged. John Wiley & Sons, Inc., New York, 1920. Cloth, 6 × 9 in., 563 pp., illus., tables, $6.

This collection of analytical methods, by the chief of a large steel-works laboratory, represents the results of long experience in the rapid examination of steel-works materials. Many methods are original. The present edition has been expanded to include a considerable number of new methods which have been developed since the last revision of the book.

Relativity; The Special and the General Theory. By Albert Einstein. Translated by R. W. Lawson. Henry Holt & Co., New York, 1920. Cloth, 6 × 9 in., 181 pp., port., $3.

Dr. Einstein has attempted, as far as possible, to give an exact insight into the theory of relativity to those readers who are interested in it, from a general scientific and philosophical viewpoint, but who are not conversant with the mathematical apparatus of theoretical physics. The book assumes more than an elementary education and, despite the shortness of the book, a fair amount of patience and force of will, will be necessary to comprehend it. The author, however, has spared no pains in the endeavor to present the main ideas in the simplest and most intelligible form.

(Reg. U. S. Pat. Off.)

THE ENGINEERING INDEX presents each month, in conveniently classified form, items descriptive of the articles appearing in the current issues of the world's engineering and scientific press of particular interest to mechanical engineers. At the end of the year the monthly installments are combined along with items dealing with civil, electrical, mining and other branches of engineering, and published in book form, this annual volume having regularly appeared since 1906. In the preparation of the Index by the engineering staff of The American Society of Mechanical Engineers some 1200 technical publications received by the Engineering Societies Library (New York) are regularly reviewed, thus bringing the great resources of that library to the entire engineering profession.

Photostatic copies (white printing on a black background) of any of the articles listed in the Index may be obtained at a price of 25 cents per page, plus postage. A separate print is required for each page of the larger periodicals, but wherever possible two small or medium-sized pages will be photographed together on the same print. The bill will be mailed with the print. When ordering photostats identify the article by quoting from the Index item: (1) Title of article; (2) Name of periodical in which it appeared; (3) Volume, number, and date of publication of periodical; (4) Page numbers. Orders should be sent to the Engineering Societies Library, 29 West 39th Street, New York.

ACCIDENTS

Building Construction. Keeping Track of Construction Accidents. Contract Rec., vol. 34, no. 45, Nov. 10, 1920, pp. 1078–1081. Describes systematic method of checking safety. Report adopted by Construction Section of Nat. Safety Council.

AERONAUTICAL INSTRUMENTS

Bearings, Efficiency of. The Efficiency of Small Bearings in Instruments of the Type Used in Aircraft, F. H. Norton. Nat. Advisory Committee for Aeronautics, report no. 94, 1920, 10 pp., 18 figs. Research at laboratory of Nat. Advisory Committee for Aeronautics, Langley Field, Virginia. Static and running friction for thrust and radial loads, was determined for several conical pivots and for plain cylindrical and ball bearings. It was found that for given small load conical pivots give less friction than any other type. When load exceeds 1000 grams ball bearings give less friction than pivots and stand shocks and wear better.

Inclinometers. Airplane Flight Instruments, Kurt Bennewitz. Aviation, vol. 9, no. 11, Nov. 29, 1920, pp. 346–348, 8 figs. Inclinometers with stationary system of references, and with moving system of reference. Translated from Technische Berichte.

AERONAUTICS

Standard Atmosphere. Standard Atmosphere (Sur l'atmosphère standard), P. Grimault. Aéronautique vol. 2, no. 14, July 1920, pp. 93–96, 6 figs. Standard adopted by Ministry of Aeronautics and Aerial Transport of France for official testing of aeroplanes.

Tests. Distribution of Pressure on Cylinder Whose Generatrix is Perpendicular to the Air Current (Sur la distribution des pressions autour des cylindres dont les génératrices sont perpendiculaires au courant d'air) A. Toussaint. Aéronautique, no. 11, April 1920, pp. 493–500, 19 figs. Records of experiments. (Concluded.)

AEROPLANE ENGINES

Aeromarine U-8. Aeromarine U-8 180 Hp. Engine. Aviation, vol. 9, no. 12, Dec. 6, 1920, pp. 387–388, 3 figs. Water-cooled 8-cylinder V-type. Total weight of engine, 550 lb.

American. Modern Aviation Engines—VI, K. H. Condit. Am. Mach., vol. 53, no. 23, Dec. 2, 1920, pp. 1042–1044, 6 figs. Representative American designs for commercial aviation.

Carburetors. See CARBURETORS.

German Diesel. A German Diesel Airplane Engine Aviation, vol. 9, no. 9, Nov. 15, 1920, pp. 287–288, 2 figs. Engine operates on two-cycle principle. It has no carburetor, fuel being injected directly into cylinders. It has no valves. There are two opposed pistons per cylinder and two crankshafts connected by gearing at one end.

Italian. Modern Aviation Engines—V, K. H. Condit. Am. Mach., vol. 53, no. 21, Nov. 18, 1920, pp. 936–938, 5 figs. Italian types.

Pressure Gages. Pressure Gages for Airplanes. Aviation, vol. 9, no. 11, Nov. 29, 1920, pp. 357–8, 2 figs. Instructions for installing gages.

Starters. Comparative Test of Auxiliary Starting Devices for the Liberty Engine. Air Service Information Circular, vol. 2, no. 3, Sept. 25, 1920, 7 pp., 6 figs. Object of test was to compare ease of starting of 12-cylinder Liberty engine equipped with two auxiliary starting devices designed by Engineering Division, Air Service.

New Ignition End Bijur Airplane Engine Starter. Automotive Manufacturer, vol. 62, no. 8, Nov. 1920, pp. 31–32, 2 figs. Details of new self-contained starter, particularly adapted to Liberty motors.

Wright. New Wright Aeronautical Engine. Aviation, vol. 9, no. 13, Dec. 13, 1920, pp. 420–423, 7 figs. Latest design manufactured by Wright Aeronautical Corp'n, manufacturers of Wright-Hispano engine.

AEROPLANE PROPELLERS

Blade-Screw Theory. A Few Remarks Concerning Some Fundamentals of the Theory of Blade-Screws, George de Bothezat. Aeronautical Jl., vol. 24, no. 119, Nov. 1920, pp. 595–600, 1 fig. Generalized form of fluid resistance met in case of blade screw.

Design. Screw Propellers, M. A. S. Riach. Aeronautics, vol. 19, nos. 368, 370, 371 and 372, Nov. 4, 18, 25 and Dec. 2, 1920, pp. 327–328, 362–365, 377–378 and 401–402, 6 figs. Nov. 4: Design formulas. Nov. 18: Equations of motion. Nov. 25: Formulas for determining stresses. Dec. 2: Relation between "momentum" and "aerofoil" theories of propeller, assuming "inflow" as theory basis. (Continuation of serial.)

Variable-Pitch. The Oddy Variable Pitch and Reversing Propeller, A. M. Buckwald. Aerial Age, vol. 12, no. 11, Nov. 22, 1920, p. 299, 1 fig. Propeller exhibited at London Aero Show.

Variable-Pitch Propeller for Flying at High Altitudes (Hélices à pas variable pour le vol aux grandes altitudes), J. Stroescu et D. Cusmanovici. Aérophile, vol. 28, nos. 17–18, Sept. 1–15, 1920, pp. 272–273, 4 figs. Patented design.

AEROPLANES

Aerofoils. The Wragg Adjustable Compound Aerofoil, C. A. Wragg. Aerial Age, vol. 12, no. 13, Dec. 6, 1920, p. 346, 2 figs. Device for enabling wider speed variation. It consists of using two aerofoils suitable for very high speed and placing them at low incidence, one behind and a little below the other so that there is a small gap between them.

Avro "Baby." Two-Seater Avro "Baby" Biplane, Type 543. Flight, vol. 12, no. 45, Nov. 4, 1920, pp. 1145–1147, 6 figs. Also Aeronautics, vol. 19, no. 368, Nov. 4, 1920, p. 326, 2 figs. Dimensions: Span of top plane 25 ft. Span of bottom plane, 23 ft.; gap between planes, 4 ft. 3 in.; length overall, 20 ft.; height overall, 7 ft. 6 in.; area of planes and ailerons, $176\frac{1}{2}$ sq. ft.; weight loaded, 970 lb.; maximum speed sea level, 82 m.p.h.; cruising speed at 1000 ft., 70 m.p.h.

Balancing. A Method for Determining the Angular Setting of a Tail Plane to Give Balance at any Given Condition, L. V. Kerber and W. F. Gerhardt. Aerial Age, vol. 12, no. 14, Dec. 13, 1920, pp. 370–373, 1 fig. Method includes determination of proper angular setting of horizontal tail plane to give longitudinal balance at level flight at any given speed, climbing flight at best rate of climb and when gliding at any angle with power off.

Bischoff. The Bischoff Small Aeroplane (L'avionnette de Pischoff), R. Esnault-Pelterie. Aerophile, vol. 28, nos. 17–18, Sept. 1–15, 1920, pp. 266–268, 2 figs. Dimensions: Length, 3.52 m.; height, 1.3 m.; width, 5.2 m.; total weight, empty, 102 kgr.; speed, 90 kw. per hr.

Centering. Centering Aeroplanes (Centrage des Avions), L. Huguet. Vie Technique et Industrielle, vol. 1, no. 9, June 1920, pp. 207–210, 6 figs. Influence of various elements of aeroplane upon its longitudinal stability in flight. (Continuation of serial.)

Design. Some Requirements of Modern Aircraft. Eng., vol. 110, no. 2864, Nov. 19, 1920, pp. 683–684, 6 figs. Requirements of aeroplanes for commercial aviation service.

Elevator Weight. The Effect of Elevator Weight, F. H. Norton. Aviation vol. 9, no. 14, Dec. 20, 1920, pp. 458–459, 3 figs. Effect of stability and controlability of elevator weight.

F.I.A.T. The F.I.A.T. Twelve-Seater Biplane. Flight, vol. 12, no. 47, Nov. 18, 1920, pp. 1189–1191, 6 figs. Characteristics: Span, top plane, 68 ft. 10 in.; span, lower plane, 69 ft. 9 in.; chord, 10 ft. 6 in.; overall length, 43 ft. 9 in.; overall height, 14 ft. 9 in.; weight, loaded, 11,000 lb.; speed range, 50–125 m.p.h.; ceiling full load, 15,000 ft.

Figure of Merit. A Figure of Merit for Airplanes, Donald W. McIlhiney. Aviation, vol. 9, no. 8, Nov. 8, 1920, pp. 254–257, 2 figs. It is suggested to use as figure of merit, ratio of the product of weight per horsepower times velocity at 90 per cent maximum times pay load times range, to product of landing velocity times total weight.

Flying Boats. See FLYING BOATS.

Fokker. Fokker Commerical Airplanes. Aviation, vol. 9, no. 12, Dec. 6, 1920, pp. 385–386, 3 figs. Cantilever monoplane type. Specifications: Engine, 185 hp. B.M.W.; span overall, 56 ft. 3 in.; length overall, 37 ft. 10 in.; height, 12 ft.; weight, fully loaded, 4125 lb.

Giant. Post-War Types of Giant Aeroplanes (Les avions géants d'après-guerre), Jean-Abel Lefranc. Nature (Paris), no. 2430, Oct. 30, 1920, pp. 276–285, 2 figs. Survey of developments. (To be continued.)

Glenn L. Martin. The Glenn L. Martin Commercial Transport Biplane. Aviation, vol. 9, no 13, Dec. 13, 1920, pp. 426–428, 2 figs. Also Aerial Age, vol. 12, no. 15, Dec. 20, 1920, pp. 392–394, 3 figs. Specifications: Span, overall, 74 ft. 2 in.; length, overall, 43 ft. $7\frac{5}{16}$ in.; height, overall, 15 ft. $6\frac{3}{4}$ in.; total weight 12,000 lb.; power plant, 2 Liberty 12-cylinder V-type engines; maximum speed 110 m.p.h.

Helicopters. See HELICOPTERS.

Hydroplanes. See HYDROPLANES.

Lincoln Standard Cruiser. The Lincoln Standard Cruiser. Aerial Age, vol. 12, no. 12, Nov. 29, 1920, pp. 319–321, 5 figs. Specifications: Length overall, 26 ft. 4 in.; span, 41 ft.; chord, 6 ft.; weight, total, 3150 lb.; motor, 220 hp. Hispano-Suiza; maximum Speed, 95 m.p.h.; range, 350 miles.

Loening. The Loening Special Monoplane. Aerial Age, vol. 12, no. 15, Dec. 20, 1920, pp. 394–395, 2 figs. Dimensions: Overall length, 24 ft. $2\frac{1}{2}$ in.; overall height, 6 ft. 7 in.; total weight, 1850 lb.

Metallic Construction. The Utilization of Metallic Structures in Aeroplanes (L'utilisation des profilés

métalliques dans la construction des aéroplanes). Aéronautique, vol. 2, no. 14, July 1920, pp. 52–54, 19 figs. Metals used, types of structures and methods of joining.

Model, Experiments with. Some Experiments with Model Airplanes, Albert A. Merrill. Aviation, vol. 9, no. 11, Nov. 29, 1920, p. 349, 2 figs. Experiments made in Eiffel's laboratory and National Physical Laboratory in England to determine static stability in pitch for models with elevator set in various positions.

Nieuport. The Battle Plane Nieuport (Le monoplane de combat Nieuport 29 C-1). Aéronautique, vol. 2, no. 14, July 1920, pp. 61–65, 7 figs. Characteristics: Span, 9.80 m.; length, 6.65 m.; height, 2.56 m.; engine, Hispano-Suiza, 300 hp.

Nieuport London. The Nieuport "London" Night Bomber. Flight, vol. 12, no. 49, Dec. 2, 1920, pp. 1231–1239, 23 figs. Triplane designed and built by Nieuport & General Aircraft Co., Cricklewood, England. Characteristics: Length overall, 37 ft. 6 in.; span, 59 ft. 6 in.; height, 18 ft.; engines two 320 hp. A.B.C. "dragonfly" engines mounted between lower and middle plane.

Passenger. The Unusual in Passenger-Carrying Airplanes, Alfred Longville. Sci. Am., vol. 123, no. 25, Dec. 18, 1920, p. 609, 3 figs. Recent developments in Germany and Italy.

Ranges. A Study in Aeroplane Ranges and Useful Loads, J. G. Coffin. Flight, vol. 12, nos. 47 and 48, Nov. 18 and 25, 1920, pp. 1199–1201, 2 figs., and 1214–1216, 3 figs. Nov. 18: Theory of maximum range conditions. Nov. 25: Effect of wind on range calculations.

Single- vs. Twin-Engined. A Comparison of Single- and Twin-Engined Aeroplanes, R. M. Hill. Aeronautics, vol. 19, no. 368, Nov. 4, 1920, pp. 320–321. Comparison from pilot's point of view. (Concluded.) Paper read before Royal Aeronautical Society.

Skylark. The Skylark. Aviation, vol. 9, no. 8, Nov. 8, 1920, p. 267, 1 fig. Dimensions: Average length, 22 ft. 6 in.; height, 7 ft.; total weight, empty, 730 lb.; machine, three-cylinder, 60 hp., Lawrence air-cooled engine.

Spars. The Design of Spars with Offset Pin Joints, Harris Booth. Aeronautical Jl., vol. 24, no. 118, Oct. 1920, pp. 563–574. Stresses in bay of spar under different loads. Design formulas.

Sperry Messenger. The Sperry Messenger Airplane. Aviation, vol. 9, no. 9, Nov. 15, 1920, pp. 285–286, 5 figs. Specifications: Span, 20 ft.; length, 17 ft. 9 in.; height, 7 ft.; weight, empty, 581 lb.; high speed, 95 m.p.h.; climb in 10 min., 10,000 ft.

Sport. A German Sport Monoplane. Aviation, vol. 9, no. 12, Dec. 6, 1920, p. 391. Designed by Sablatnig Flugzeughau Cie Specifications: Engine, 3 cylinder, 20 hp. air-cooled; weight, empty, 185 kg.; span, 8.40 m.; length, 5.30 m.; height, 2.20 m.; speed, 110 km. per hr.

Two American Sportplanes. Flight, vol. 12, no. 45, Nov. 4, 1920, pp. 1156, 2 figs. W.A.C.O. "Cootie" and U. S. Airplane Co.'s "L.C.7." Dimensions: "Cootie," overall span, 22 ft.; overall length, 16 ft.; total wing area, 85 sq. ft.; speed range, 35 to 65 m.p.h.; climb, 4000 ft. in 10 min. Dimensions of "L.C.7," span, 26 ft.; overall length, 20 ft. 1 in.; overall height, 6 ft. 8 in.; speed range, 26 to 85 m.p.h.

Stability. Aerodynamic Study of the Supporting Members of an Aeroplane (L'étude aérodynamique des organes sustentateurs d'avion), M. Rocca. Aéronautique, vol. 2, nos. 14 and 15, July and Aug. 1920, pp. 87–91, 3 figs., and 129–123, 8 figs. Prantl method as set forth in the German press.

Steam Turbine for. The Study of a Steam Turbine for Airplanes, Luigi Acvampora. Aviation, vol. 9, no. 8, Nov. 8, 1920, pp. 261–262. Possibilities of designing steam turbine for propeller aeroplane. Advantages of such system of propulsion over internal-combustion engine.

Testing Railway. The Aerial Testing Railway of the German Experimental Station for Aviation and Discussion of the Propeller Drive for Railroad Cars (Die Flugzeugprüfbahn der Deutschen Versuchsanstalt für Luftfahrt und über den Luftschraubenantrieb für Eisenbahnfahrzeuge), H. Bendemann. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol. 11, nos. 17 and 18, Sept. 15 and 30, 1920, pp. 245–252 and 261, 12 figs. Description of tower supporting aeroplane to be tested which is mounted on a heavy car truck and drawn by locomotive, by means of which the aeroplane can be moved with great speed through air. Notes on method and arrangement used for measuring air forces to which aeroplane is subjected according to magnitude, direction and position. Details of car designed for carrying out aerodynamic measurements, which is driven by a 240-hp. Maybach engine with direct-coupled propeller; points out its useful possibilities for gaging speed-measuring instruments, etc.

A Railway for Testing Full Size Airplanes. Aviation, vol. 9, no. 14, Dec. 20, 1920, pp. 455–457, 7 figs. Steel tower fastened on railway car truck carries aeroplanes on top. Engine pulls structure at full speed and rating of performance of aeroplane under conditions of test are taken. Mechanism was devised to substitute for wind-tunnel model testing. Paper read before German Aeronautical Society.

Tests. Static Tests of Aeroplanes (Essais statiques des avions), Paul Boccacio. Aéronautique, vol. 2, no. 17, Oct. 1920, pp. 190–195, 8 figs. Methods of procedure.

Tests in Flight and the Laws of Aerodynamics (Les essais en vol et les lois de l'aérodynamique), Ch. Robin. Aéronautique, no. 3, Mar. 1920, pp. 431–436, 12 figs. Equipment developed for conducting aeronautical research in an aeroplane in flight.

Transport. Proposed Transport Airplane. Aviation, vol. 9, no. 100, Nov. 22, 1920, p. 321, 1 fig. Dimensions: Span, 125 ft.; overall height, 19 ft.; length overall, 75 ft.; total area, 3864, sq. ft.; maximum speed, 130 m.p.h.; total weight, 18.5 tons.

Variable-Surface. A French Variable Wing. Aeronautics, vol. 19, no. 372, Dec. 2, 1920, p. 391, 3 figs. Gastambide-Levavasseur design.

Another New Wing. Aerial Age, vol. 12, no. 11, Nov. 22, 1920, p. 297, 2 figs. Developed by Levavasseur, inventor of Antoinette monoplane.

The New Variable Surface Airplane, H. M. Buckwald. Aviation, vol. 9, no. 10, Nov. 22, 1920, pp. 314–316, 6 figs. Levavasseur and Gastambide is a tractor biplane fitted with 250 hp. Salmson engine. Pilot can vary surface, while in flight, from 345 sq. ft. to 560 sq. ft., by sliding panels in the upper plane.

Wings. The New Handley Page Aeroplane Wing. Engr., vol. 130, no. 3383, Oct. 29, 1920, p. 421, 2 figs. Slotted wing form. In trial tests, slotted machines rose at sharper angle, climbed more quickly, alighted at much slower speed and pulled up in considerably shorter distance than ordinary type.

Why the Wing of Uniform Section May Survive, Douglas Shaw. Aeronautics, vol. 19, no. 370, Nov. 18, 1920, p. 359. Because of its comparatively low cost of production. It is besides aerodynamically justified and desirable, and is a sound engineering compromise.

See also Variable-Surface.

AIR BRAKES

Defects. Car Failures Caused by Improper Brake Maintenance, E. H. Wood. Official Proc. Car Foreman's Assn., vol. 16, no. 2, Nov. 1920, pp. 21–33 and (discussion) pp. 34–71, 7 figs. Classification and discussion of principal defects in brake apparatus that cause car failures.

Swedish National Railways. The New Pneumatic Brake for Freight Trains of the Swedish National Railways (Statens järnvägsgars nya godstagsbroms), Gustaf Rydberg. Teknik Tidskrift (Veckoupplagan), vol. 50, no. 40, Oct. 2, 1920, pp. 437–443, 11 figs. Points out that a one-chamber brake does not fulfil requirements of a freight-train pneumatic brake, and describes various improvements of which the Kunze-Knorr brake, a combination of the one- and two-chamber brake, is said to be the best, the braking effect being 60 per cent greater than with a one-chamber brake of corresponding size.

AIR COMPRESSORS

High-Pressure. High-Pressure Compressors (Hochdruckkompressoren), V. v. Haaren. Zeit. des Vereines deutscher Ingenieure, vol. 64, nos. 44 and 46, Oct. 30 and Nov. 13, 1920, pp. 901–906 and 959–962, 26 figs. Recent development of high-pressure compressors for recovery of oxygen and nitrogen from the air, for production of ammonia according to the Haber process, and for operation of compressed-air mine railways, etc. Notes on different types; selection and arrangement of stages; cylinders; valves; stuffing boxes; lubrication of cylinders; packings; 5-stage mine compressors; compressors for chemical industry; and vertical compressors for use on board ships.

Lubrication. Lubrication of Air Compressors, H. V. Conrad. Glass Industry, vol. 1, no. 2, Dec. 1920, pp. 41–43, 1 fig. Practice recommended by Compressed Air Society.

AIR-HOSE LINES

Couplers. Making Thor Quick-Action Air Line Couplers, J. V. Hunter. Am. Mach., vol. 53, no. 21, Nov. 18, 1920, pp. 931–933, 10 figs. Machining operations used in producing couplers in large quantities.

AIRCRAFT CONSTRUCTION MATERIALS

Casein Glue. Failure of Casein Glue Joints in Ash Louis J. Bradford. Aerial Age, vol. 12, no. 13, Dec. 6, 1920, pp. 346–347, and 354, 4 figs. Results of tests showed that both casein and hide glues possess sufficient strength to break spruce. With ash, however, hide-glue joints showed over double strength of those made with casein glue.

Wire Cables. Wire Cables, Walter A. Scoble. Aeronautical Jl., vol. 24, no. 118, Oct. 1920, pp. 537–562, 3 figs. Tests on wire rope under tension, shock and vibration. Bearing of core diameter on strength of cables. Cables tested were of types used in aeronautics.

AIRSHIPS

Commercial. The Commercial Airship—Its Operation and Construction, Trevor Dawson. Flying, vol. 9, no. 11, Dec. 1920, pp. 665–673, 9 figs. Traffic possibilities of airships. Size of airship required. Development of mooring power. Possibilities of reducing cost of construction and operation.

German. The German Airships L 64 and L 71. Automobile Engr., vol. 10, no. 144, Nov. 1920, pp. 445–447, 6 figs. Notes on their machinery installations.

Hangars. See HANGARS.

Wiring of. The Transverse Wiring of the Rigid Airship, E. H. Lewitt. Aeronautics, vol. 19, no. 372, Dec. 2, 1920, pp. 397–400, 6 figs. Theoretical investigation into magnitude and variation of tensions in transverse wires of rigid airship caused by pressure of adjoining gas bag.

ALCOHOL

See AUTOMOBILE FUELS, Alcohol.

ALLOY STEELS

Analysis. The Analysis of Special Steels, C. O Bannister. Elecn., vol. 85, no. 2216, Nov. 5, 1920, pp. 535–538, 5 figs. Use of electrometric titration methods.

Comparative Efficiency. A Suggested Method for Determining the Comparative Efficiency of Certain Combinations of Alloys in Steel, J. D. Cutter. Trans. Am. Soc. for Steel Treating, vol. 1, no. 3, Dec. 1920, pp. 188–190 and (discussion) pp. 190–3, 198, 7 figs. Formula for merit index is given. Efficiency is defined as ratio of effect produced to energy expended.

Effect of High Temperature. Comparative Values of Motor Valve Steels, G. Gabriel. Iron Age, vol. 106, no. 23, Dec. 2, 1920, pp. 1465–1469, 1 fig. Analysis of effects of high temperature on physical properties of tungsten, chrome and nickel steels. Translated from La Technique Automobile et Aérienne.

ALLOYS

Nickel-Chromium. See NICKEL-CHROMIUM ALLOYS.

ALUMINUM

Casting Losses. Analyze Loss in Aluminum Shops—I, Robert J. Anderson. Foundry, vol. 48, no. 24, Dec. 15, 1920, pp. 989–992. Replies to questionnaires on casting losses are analyzed and study is made of causes for and prevention of defects in castings. Enumeration of principal typical faults.

APPRENTICES, TRAINING OF

Prussian-Hessian State Railways. The Training of Fitter-Apprentices in the Workshops of the Prussian-Hessian State Railways, W. J. Horne. So. African Jl. of Sci., vol. 16, no. 5, April-July 1920, pp. 411–425. List of practical exercises at training workshops for apprentices.

Systems. Programs of Apprenticeship and Special Training in Representative Corporations—V, J. V. L. Morris. Am. Mach., vol. 53, no. 21, Nov. 18, 1920, pp. 951–952, 4 figs. System of training machinists used in plant of Sperry Gyroscope Co., Brooklyn, N. Y.

Programs of Apprenticeship and Special Training in Representative Corporations, J. V. L. Morris. Am. Mach., vol. 53, no. 24, Dec. 9, 1920, pp. 1078–1080, 5 figs. Apprenticeship system of De La Vergne Machine Co., New York.

ASH HANDLING

German Power Plants. Ash Removal in Large Power Plants (Die Aschenbeseitigung in Grosskraftwerken), Ph. Scholtes. Elektrische Kraftbetriebe u. Bahnen, vol. 18, no. 26, Sept. 14, 1920, pp. 217–222, 13 figs. on supp. plate. Review of previous literature and summary of replies to a circular letter to large power plants in Germany; critical comparison of the different systems; practice at the Franken central station at Nuremburg; requirements of an ash-removal plant and list of firms engaged in their construction.

AUTOMOBILE ENGINES

Air Cooling. The Position of Air-Cooling, B. H. Davies. Autocar, vol. 45, no. 1310, Nov. 27, 1920, pp. 1055–1058, 12 figs. Review of present situation and possible lines of development.

British Designs. Tendencies in British Engine Design Noted at Olympia, M. W. Bourdon. Automotive Industries, vol. 43, no. 22, Nov. 25, 1920, pp. 1060–1065 and 1067, 18 figs. Most notable type observed by writer was carefully designed, small-powered car. (To be continued.)

Hot-Spot. Comparative Tests with a Hot-Spot Device, Roy E. Berg. Automobile Industries, vol. 43, no. 24, Dec. 9, 1920, pp. 1170–1173, 5 figs. Dynamometer tests made in engine laboratory of Lewis Institute showed appreciable fuel economy over wide range speed, smoother low speed, throttle operation and reduced crankcase dilution with Losee hot-spot device fitted to six-cylinder engine.

Properly Applied Heat—An Answer to the Fuel Question, Roy E. Berg. Motor Age, vol. 38, no. 20, Nov. 11, 1920, pp. 7–10, 9 figs. Tests on six-cylinder engine fitted without and then with hot-spot of replacement type.

Manufacture. Building Motors on the Pacific Coast, Fred. H. Colvin. Am. Mach., vol. 53, no. 43, Dec. 16, 1920, pp. 1117–1121, 24 figs. Methods at works of Hall-Scott Motor Car Co.

Machining Operations on the Nash Motor. Machy. (Lond.), vol. 17, no. 424, Nov. 11, pp. 171–174, 8 figs. Use of special machines and methods of equipping standard machine tools.

Nash. Nash Engine is Adapted to Four-Cylinder Practice, Roy E. Berg. Automotive Industries, vol. 43, no. 22, Nov. 25, 1920, pp. 1055–1058, 5 figs. New product closely follows six-cylinder features with latest combustion refinements. Lubrication of power plant is through positively driven gear pump. Chassis of 112-in.-wheelbase is employed for four models of cars on 1921 program. New constructional features described.

Radiators. Automotive Radiators, Karl F. Walker. Jl. Soc. Automotive Engrs., vol. 7, no. 6, Dec. 1920, pp. 549–553, 6 figs. Curves showing relation between core depth and heat-dissipating capacity, and effect of water flow on heat-dissipating capacity.

Ricardo Crosshead Piston. The 150 H.P. Ricardo Crosshead Piston Engines, S. Findlater. Automobile Engr., vol. 10, no. 145, Dec. 1920, pp. 490–491, 2 figs. Notes on their performance on test in tanks.

Alcohol and Motive Power (L'alcool et la force motrice), Albert Ranc and Jacques Boisseau. Nature (Paris), no. 2429, Oct. 23, 1920, pp. 260–263. Survey of studies made to determine applicability of alcohol as automobile fuel.

Researches on Alcohol as an Engine Fuel, Harold B. Dixon. Jl. Soc. Automotive Engrs., vol. 7, no. 6, Dec. 1920, pp. 521–524. It was found that alcohol possesses most of properties required in engine fuel. As compared with gasoline its lower calorific value is claimed to be compensated by greater compression at which it can be used and this property of high ignition temperature under compression is hardly altered by admixture with 20 per cent benzine or gasoline itself. (Abstract.) Report to Fuels Section of Imperial Motor Transport Conference, London.

Benzol-Alcohol Mixtures. Benzol-Alcohol Experiments on Omnibuses, G. J. Shave. Eng., vol. 110, no. 2862, Nov. 5, 1920, pp. 623–624. Fuel experiments carried out by London General Omnibus Co. Paper read before Imperial Motor Transport Council, London.

Gasoline. See GASOLINE.

Mixtures. Fuel Mixtures on London Omnibuses, G. J. Shave. Jl. Soc. Automotive Engrs., vol. 7, no. 6, Dec. 1920, pp. 556–557. Experiments carried out with a view to ascertaining most suitable mixture of benzol-alcohol for use in standard buses. Mixture of composition, alcohol 65 per cent, benzol 30 per cent and ether 5 per cent, has given satisfactory results with water-jacketed intake pipe. (Abstract.) Paper read before Fuels Section of Imperial Motor Transport Conference, London.

Petroleum. Use of Petroleum in Automobile Engines. (Petroleumbetrieb), H. Praetorius. Motorwagen, vol. 23, no. 25, Sept. 10, 1920, pp. 465–472, 11 figs. Account of examination, by the Technical Commission of Automobile Club of France in collaboration with Gen. Automobile Assn. and Syndical Chamber of Petroleum Industries, of the Aldo, the Genault and the Bellem & Brégéras carburetors; and details of the Egtal pump, with which test was made using mixture of 40 per cent benzine and 60 per cent petroleum in engine of 4-cylinder automobile of latest construction with 80 mm. bore and 130 mm. stroke, and with 1800 revolutions an output of 30 hp. was achieved with fuel consumption of 270 gr. per hp-hr.

AUTOMOBILES

Bignan-Sport. The Refined Bignan-Sport, W. F. Bradley. Automotive Industries, vol. 43, no. 20, Nov. 11, 1920, pp. 956–958, 5 figs. Details of automobile of French production exhibited at Olympia Show, London. Lubrication of engine is under pressure and each bearing is fitted with oil collector which returns excess oil to base chamber. It is declared that oil consumption is only at rate of one gallon for 3000 miles.

Body Design. New Ideas in the Construction of Automobile Bodies (Neue Gesichtspunkte bei der Konstrukion von Automobil-Karosserien), Max Buch. Motorwagen, vol. 23, no. 25, Sept. 10, 1920, pp. 463–465, 6 figs. Description of automobile body constructed by author, an open car which in less than a minute can easily be transformed into a completely closed limousine or sedan.

Differential Casings. Machining Worm-driven Differential Casings. Eng. Production, vol. 1, no. 13, Dec. 1920, pp. 477–482, 17 figs. Description of methods employed.

Front-Axle Swivels. Front-Axle Swivels. Automobile Engr., vol. 10, no. 145, Dec. 1920, pp. 478–479, 5 figs. Justification of vertical steering pivots.

Gear Ratio vs. Car Economy. Effect of Gear Ratio on Car Economy. J. N. Golten and Allan Neumann. Automotive Industries, vol. 43, no. 24, Dec. 9, 1920, pp. 1167–1169, 8 figs. Methods of obtaining best car performance with respect to fuel economy when using various gear ratios. Graphs and experimental data.

Locking Gear. The Goodheart Differential. Motor Traction, vol. 31, no. 818, Nov. 1, 1920, pp. 513–514, 4 figs. Automatic locking gear which eliminates wheel spinning.

Olympia Show. Public at London Show Interested in Economical Car, M. W. Bourdon. Automotive Industries, vol. 43, no. 20, Nov. 11, 1920, pp. 951–954, 8 figs. Few important engineering changes are reported in automobile exhibition recently held at Olympia, London.

The Automobile Show. Automobile Engr., vol. 10, no. 145, Dec. 1920, pp. 486–489, 14 figs. Trend of design as shown by exhibits in International Exhibition at Olympia and White City.

Peugot. The 11 H.P. Peugot Chassis. Automobile Engr., vol. 10, no. 145, Dec. 1920, pp. 482–485, 12 figs. Light French car with 10 hp. engine.

Transmission Case. Franklin Transmission Case, Fred. H. Colvin. Am. Mach., vol. 53, no. 22, Nov. 25, 1920, pp. 1001–1004, 10 figs. Machining operations.

AVIATION

Aerial Routes. Climatological Factors Governing the Selection of Air Routes and Flying Fields, C. LeRoy Meisinger. Aerial Age, vol. 12, no. 14, Dec. 13, 1920, pp. 368–369 and 373. Importance of meteorological studies in connection with the establishment of aerial routes and layouts of flying fields.

Canadian Air Board Report. Report of Canadian Air Board. Aviation, vol. 9, no. 8, Nov. 8, 1920,

Civil. Civil Aviation. Aeronautical Jl., vol. 24, no. 119, Nov. 1920, pp. 579–590 and (discussion) pp. 590–594. Growth and present position of air mail, passenger and goods services, specially in United Kingdom and British Dominions and Colonies. Factors contributing to successful air services, and suggestions for their successful future development.

Civil Aviation and Air Services, F. H. Sykes. Flying, vol. 9, no. 11, Dec. 1920, pp. 674–679, 2 figs. Growth and present position of air mail, passenger and goods services. Factors contributing to successful air services.

The Organization of Civil Aviation Along International Lines, William Knight. Aerial Age, vol. 12, no. 13, Dec. 6, 1920, pp. 344–345. Urges creation of powerful organization that will establish and operate aerial lines of communication between most important centers of the world, and will take initative in framing up legislation needed for governing navigation of air.

Commercial, German. Commercial Aviation in Germany. Aeronautics, vol. 19, no. 371, Nov. 25, 1920, pp. 375–376, 1 fig. Recent developments. Map of air routes established. (To be concluded.)

Course Determination. Route Correction—A New Method of Aerial Navigation (Correcteur de route; nouvelle méthode de navigation aérienne à l'estime), M. Le Prieur. Comptes rendus des Séances de l'Académie des Sciences, vol. 171, no. 16, Oct. 18, 1920, pp. 700–702. Aerial navigation by means of "derivograph," air apparatus which determines direction to be followed, corrected for wind, in order to reach a given place by straight line flight

Hazards. Effective Study of Aviation Hazards Begun. Automotive Industries, vol. 43, no. 21, Nov. 18, 1920, pp. 1026–1027. Preliminary reports by Committee on Aviation Hazards of National Safety Council.

Mail Service. The Air Postman, H S. Holt. Aeronautics, vol. 19, no. 370, Nov. 18, 1920, p 360. Equipment required at terminal points. Organization of mail service.

Night Flying. Night Flying, Cecil Baker. Aeronautics, vol. 19, no. 368, Nov. 4, 1920, pp. 323–325. Experience during war. Problems of low flying, finding way, and landing.

Spins. Spins. Flight, vol. 12, no. 47, Nov. 18, 1920, pp. 1192–1195, 6 figs. How to describe a spin. Precautions to take. Stresses in aeroplane. Paper read before Cambridge University Aeronautical Society.

Switzerland. Aerial Navigation in Switzerland (La navigation aérienne en Suisse), E. H. Lémonon. Aerophile, vol. 28, nos. 17–18, Sept. 1–15, 1920, pp. 274–277, 2 figs. Development of aviation in Switzerland.

[See also FLIGHT.]

AXLES

Heat-Treating. Plant for Heat Treating Automobile Axles, L. M. Thomas. Am. Drop Forger, vol. 6, no. 11, Nov. 1920, pp. 533–536, 3 figs. Plant of Timken-Detroit Axle Co. Automatic annealing furnaces are used.

B

BALANCING

Slow-Speed vs. High-Speed. Slow-Speed vs. High-Speed Balancing, N. W. Akimoff. Am. Mach., vol. 53, no. 21, Nov. 18, 1920, pp. 925–926, 1 fig. Balancing at low speeds is considered sufficiently conclusive, because if machine element cannot be balanced at such speeds, perfect balance will not be established at any speeds.

BLOWERS

Parallel Operation. The Operation of Blowers in Parallel for Forced Draft in Naval Service, M. C. Stuart and Arthur H. Sennet. Jl. Am. Soc. Naval Engrs., vol. 32, no. 4, Nov. 1920, pp. 688–718, 14 figs. Experimental investigation. It is concluded that fans operating in parallel should be run at the same speed because relatively small differences in speed cause an unequal division of load between fans in such a manner as to result in greater total shaft horsepower than would be required to produce same draft conditions with fans running at equal speeds.

BOILER FEEDWATER

Heating. The Mathematical Theory of Boiler Feedwater Heating in Steam Turbine-Driven Power Stations, Robert Dowson. Eng., vol. 110, nos. 2862 and 2863, Nov. 5 and 12, 1920, pp. 593–595, 4 figs., and 627–628. Nov. 5: Formula expressing total work lost by tapping off steam for feedwater heating. Nov. 12: Application of theory to design of group of surface feedwater heaters.

BOILERS

Construction. Examining a Steam Boiler Plant, Chas. F. Wade. Eng. & Indus. Management, vol. 5, no. 23, Dec. 2, 1920, pp. 706–710, 5 figs. Methods of construction and testing boilers. (To be continued.)

Largest in the World. The World's Largest Boilers. Power, vol. 52, no. 21, Nov. 23, 1920, pp. 828, 1 fig. Boilers being installed at Ford Plant at River Rouge, Mich. Boilers are of water-tube type and have effective heating surface of 26,470 sq. ft. each. Pulverized coal and blast-furnace gas will be burned at the same time by firing coal verstallation in France, John H. Bartlett, Jr. Chem. and Metallurgical Eng., vol. 23, no. 21, Nov. 24, 1920, pp. 1033–1035, 5 figs. Description of installation and operation of producer gas-fired boiler plant at Montrambert, Loire, Coal Mines, using coked slack and mine waste for production of gas.

Rivet Steel. Standard Specifications for Boiler Rivet Steel. Boiler Maker, vol. 20, no. 12, Dec. 1920, pp. 354–355. Revised specifications of American Society for Testing Materials.

Waste-Heat. See FURNACES, OPEN-HEARTH, Waste-Heat Boilers.

BOILERS, WATER-TUBE

Ludlum. Construction of the Ludlum Watertube Boiler. Boiler Maker, vol. 20, no. 12, Dec. 1920, pp. 345–353 and 373–374, 17 figs. Methods developed by New York Engineering Company for reducing boiler production to machine-shop basis.

BRASS FOUNDING

Electric-Furnace. Electric Furnace Has Proved Value, Carl H. Booth. Foundry, vol. 48, no. 24, Dec. 15, 1920, pp. 994–997 and 1004, 5 figs. Simplicity of construction, great flexibility and comparatively low cost of operation are some of advantages claimed for rotating type of electric brass melting furnace. Paper read before American Foundrymen's Association.

BUILDING CONSTRUCTION

Cost Accounting. Practical Means of Estimating Equipment Cost. Contract Rec., vol. 34, no. 49, Dec. 8, 1920, pp. 1161–1163. Rental schedule prepared by Associated General Contractors of America, that aims to give adequate charges for use of contracting plant.

Costs. Building Material and Construction Costs—I, Theodore F. Laist. Am. Contractor, vol. 1, no 22, Dec. 4, 1920, pp. 33–35. Study dealing with cost of building construction and of materials used in connection therewith. Brick is first material considered, being discussed under three heads, specifications, methods employed in quantity surveying and cost analysis.

Will Building Costs Come Down? Chas. F. Dingman. Concrete, vol. 17, no. 5, Nov. 1920, pp 144–146. Writer does not expect building costs to be reduced materially within next year.

Equipment. Rental Schedule for Estimating Construction Equipment Expense. Eng. and Contracting, vol. 54, no. 24, Dec. 15, 1920, pp. 583–584. Rental Schedule for construction equipment

Lightning Protection. Protection Against Lightning. Contract Rec., vol. 34, no. 47, Nov. 24, 1920, pp. 1132–1133. Procedure for rodding structures, based on practice in United States and Canada.

Office Buildings. Engineering Details of Newspaper Publishing Building, Charles F. Dingman, Eng. News-Rec., vol. 85, no. 23, Dec. 2, 1920, pp. 1092–1094, 4 figs. Building is of modified mill construction, basement and three stories in height and occupies entire area of plot 100 ft. square.

Railway Shops. Gypsum Tile as a Covering for Railroad Buildings, Curtis F. Columbia. Ry. Age, vol. 69, no. 23, Dec. 3, 1920, pp. 961–962, 3 figs. Principal characteristics of five large railway blacksmith shops.

C

CABLEWAYS

Design. Dedactic Study of Aerial Cableways (Étude didactique des transporteurs aériens sur câbles), Giulio Ceretti. Génie Civil, vol. 77, no. 21, Nov. 20, 1920, pp. 408–411, 7 figs. Characteristics of metallic cables. Notes on design. (To be continued.)

CAR COUPLERS

Universal. The Universal Car and Hose Coupler. Railroad Herald, vol. 24, no. 11, Oct. 1920, pp. 27–29, 4 figs. Features are: (1) Beveled engaging surfaces of coupler head, whereby "high and low" couplings are entirely removed; (2) locking or latch is always open and ready for use as soon as cars are uncoupled; (3) coil spring is held in groove or cavity, giving it snug fit; (4) one man can easily handle coupler shank; etc.

CARBURETORS

Automatic. Modern Automatic Carburetors for Volatile Fuels (Étude des carbureteurs automatiques modernes pour carburants volatils), A. Grebel. Génie Civil, vol. 77, no. 19, Nov. 6, 1920, pp. 370–375, 15 figs. Developments in design. (To be continued.)

Induction Systems. Induction Systems, T. L. Sherman Automobile Engr., vol. 10, no. 144, Nov. 1920, pp. 433–439, 28 figs. Comparative study of induction type of carburetors of principal areoplane engines.

Tests. The German Carburetter Trials, J. L. Chaloner. Automobile Engr., vol. 10, no. 144, Nov. 1920, pp. 450–453, 15 figs. Account of trials carried out under control of General German Automobile Club.

CARS

Brakes. See AIR BRAKES.

CARS, FREIGHT

Steel Gondola. 50-Ton Steel General Service Car, Eng., vol. 110, no. 2862, Nov. 5, 1920, pp. 604–5

and pp. 608, 16 figs., partly on supp. plate. Gondola car constructed by Pressed Steel Car Co., Pittsburgh, for Russian Government.

CASE-HARDENING

Building for. Modern Case Hardening Building at Providence. Iron Age, vol. 106, no. 24, Dec. 9, 1920, pp. 1539–1540. Features include arrangements for maximum ventilation with minimum light and dipping and cooling tanks.

[See also CRANKSHAFTS, Case-Hardening.]

CAST IRON

Carbon in. On the Crystalline Nature of Graphite and Temper-Carbon Obtained from Cast Iron, Kei Iokibé. Sci. Reports of the Tôhoku Imperial University, vol. 9, no. 4, Aug. 1920, pp. 275–279, 4 figs on supp. plate. It is concluded from investigation that the so-called graphite carbon and the temper carbon, as found in cast iron, are both the same substance as natural graphite, and since condition of decomposition of cementite is same for both steel and cast iron, the temper carbon from carbon steels will also be graphite, and not an amorphous carbon.

Influence of Nickel and Cobalt. The Influence of Nickel and Cobalt Additions on the Physical and Chemical Properties of Cast-Iron, O. Bauer and E. Piwowarsky. Foundry Trade Jl., vol. 22, no. 228, Dec. 1920, pp. 936–937. Melting experiments with cast-iron with nickel and cobalt additions.

Sulphur in. The Sulphur Problem in Cast Iron, George K. Elliott. Foundry, vol. 49, no. 24, Dec. 15, 1920, pp. 978–979. Basic electric furnace said to produce sulphur far below 0.05 per cent. Paper read before American Foundrymen's Association.

CEMENT, PORTLAND

Testing. Japanese Standard Rules for Testing Portland Cement. Cement, Mill and Quarry, vol. 17, no. 10, Nov. 20, 1920, pp. 37–38. Issued by Department of Agriculture and Commerce on Feb. 10, 1905, revised Dec. 10, 1909 and June 20, 1919. Translated by Japan Portland Cement Association.

CENTRAL STATIONS

Economics. Central-Station Costs and Income. Elec. World, vol. 76, no. 22, Nov. 27, 1920, pp. 1067–1068, 4 figs. Tendencies that appear under present conditions. Vigorous efforts are apparent to increase plant efficiency and render larger service in face of higher costs. Larger revenue helping to meet unusual requirements.

South America. Power Development in New World and Asia, L. W. Alwyn-Schmidt. Power Plant Eng., vol. 24, no. 23, Dec. 1, 1920, pp. 1113–1115. Prospects for central station. Power development in South America.

COAL

Calorific Value. Economic Value of Coal—II. Calorific Value and Relative Plant Economy with Coal as Fuel, B. S. Murphy. Power, vol. 52, no. 24, Dec. 14, 1920, pp. 936–937, 1 fig. Laboratory tests of coal.

COAL HANDLING

Bucket Cars. How Coal is Handled in South Africa. Coal Age, vol. 18, no. 24, Dec. 9, 1920, pp. 1178–1179, 3 figs. Coal is loaded into ten-ton buckets which are lifted by crane on to specially fitted car. At receiving station bucket can be removed by crane.

Central Stations. The West Penn Power Company's New Coal-Handling System. Nat. Elec. Light Assn. Bull., vol. 7, no. 12, Dec. 1920, pp. 874–875, 1 fig. Plant will elevate, screen, pick, crush, weigh and convey to bunkers of boiler-room 500 tons of coal an hour.

Motor Trucks. Youghiogheny Coal Co. Delivers 60,000 Tons Monthly by Motor Trucks, Donald J. Baker. Coal Age, vol. 18, no. 25, Dec. 16, 1920, pp. 1234–1238, 4 figs. It costs 17.5c to move one ton of coal one mile, $3.53 to operate six-ton truck one hour, and total yearly saving made by trucks over horse-drawn wagons handling same tonnage amounts to about $43,000.

COAL STORAGE

Piling. Piling Storage Coal to Prevent Fire, W. D. Langtry. Power, vol. 52, no. 21, Nov. 23, 1920, pp. 815–817, 7 figs. Suggestions in regard to choosing suitable place, avoidance of breakage in unloading, segregation of different sizes, outside sources of heat and mixing of combustible matter with coal.

COKE OVENS

By-Product. Modern By-Product Oven Operation, C. R. Bellamy. Gas Age, vol. 46, no. 9, Nov. 10, 1920, pp. 340–342, 4 figs. Results obtained by ovens built at Detroit, Mich., for Ford Co.

COMBUSTION

Air Supply. Air for Combustion. Power, vol. 52, no. 24, Dec. 14, 1920, p. 952, 2 figs. Chart showing pounds of air required per boiler horsepower, boiler and furnace efficiency and per cent excess air being given.

CONCRETE

Aggregates. The Strength of Fine-Aggregate Concrete, F. E. Giesecke, H. R. Thomas and G. A. Parkinson. Univ. of Texas Bul., no. 1855, Oct. 1, 1918, 17 pp., 5 figs. Experiments made to determine how compressive strength of concrete varies with relative quantity of cement when the maximum size of aggregate used in preparation of concrete is considerably smaller than that usually employed in concrete construction. Good concrete was prepared without use of coarse aggregate. It was found as general rule that to obtain concrete of given strength with given materials relative quantity of cement must be increased as maximum size of aggregate is decreased.

Crusher Screenings for. Crusher Screenings Make Stronger Concrete. Contract Rec., vol. 34, no. 48, Dec. 1, 1920, pp. 1138–1141. Tests made for Canadian Crushed Stone Corp'n.

Hydrated Lime, Effect of. Effect of Hydrated Lime in Concrete, Duff A. Abrams. Contract Rec., vol. 34, no. 50, Dec. 15, 1920, pp. 1183–1186. Answers to criticisms (see Contract Record, Nov. 24, 1920) of writer's original report which was based on researches regarding effect of various admixtures in concrete. Original paper was read before American Society for Testing Materials.

Proportioning. Proportioning Concrete Aggregates When Unscreened or Pit Run Gravel is Used, L. A. Doan. Eng. & Contracting, vol. 54, no. 22, Dec. 1, 1920, p. 534, 2 figs. Graphs for determining proportions of aggregates.

Recent Developments in Concrete Mixtures, H. C. Boyden. Ry. Rev., vol. 67, no. 21, Nov. 20, 1920, pp. 778–783, 7 figs. Graphs showing relations between strength of concrete and water content, relation between fineness, modulus of aggregate and strength of concrete, diagram for determining quantity of sand required in concrete mixers, and Abram's table of proportions and quantities for one cubic yard of concrete.

Tests. Pouring and Pressure Tests of Concrete, W. A. Slater and A. T. Goldbeck. Technologic Papers of Bur. of Standards, no. 175, Oct. 11, 1920, 13 pp., 4 figs. Maximum pressure against forms during pouring of concrete was found to be equivalent to that of liquid weighing about 124 lb. per cu. ft. Maximum pressure was found to be that due to head of concrete existing at end of about 40 min. After that time pressure gradually decreased in spite of increasing head of concrete.

Ten-Year Tests Showing the Effect of Age and Curing Conditions on the Strength of Concrete, M. O. Withey. Wisconsin Engr., vol. 25, no. 2, Nov. 1920, pp. 19–21, 2 figs. It is concluded that humidity of surrounding medium in which portland cement concrete is cured exercises marked effect upon its crushing strength. It was found that portland cement could be kept without deteriorating for several years when stored in tight tanks, or cylindrical galvanized-iron grain bins.

CONCRETE CONSTRUCTION

New System. A New System of Concrete Construction Making Use of Standard Wood Forms. Building Age, vol. 42, no. 12, Dec. 1920, pp. 23–25, 5 figs. Wooden permanent forms developed and patented by Samuel S. Colt.

Slabs. Diagram for Flat Slabs, O. Wolpert. Concrete, vol. 17, no. 5, Nov. 1920, pp. 142–143, 1 fig. Diagram for estimating quantity of steel and total thickness of slab required for square interior flat slabs, with drop panels, based on regulations of City of New York.

Reinforced Concrete Design Standards, C. A. P. Turner. Concrete, vol. 17, no. 5, Nov. 1920, pp. 152–155, 6 figs. Standards proposed by several associations which are criticized on basis that their reasoning is not verified by experimental evidence. It is emphasized that mathematical theory to be acceptable should be substantiated by experiment.

Reinforced Concrete Saw-Tooth Slab Design, J. W. Pearl. Concrete, vol. 17, no. 5, Nov. 1920, pp. 163–164, 2 figs. Chart for designing slabs.

Safe Loads and Deflections for "Gunite" Slabs. Can. Engr., vol. 39, no. 21, Nov. 18, 1920, pp. 525–529, 10 figs. Tests on 43 slabs at Lehigh University disclose high flexural strength, bending stress of 1800 lb. per sq. in. on $1:2^1/_2$ gunite with factor of safety of 4. Deflections were less than those for poured slabs. Reinforcement tables run up as results of experiments are included.

Standards. Proposals for New Standards for Concrete and Reinforced Concrete Construction (Entwürfe neuer Normblätter). Beton u. Eisen, vol. 19, no. 15, Sept. 20, 1920, pp. 174–180, 9 figs. Proposed standards of the German Industry Committee on Standards for cable conduits, concrete slabs for walls, holding capacity of concrete mixing machines (grinding mill and drum mixers); railway ties and coping stones of natural stone and of concrete; concrete flagstones.

Subaqueous. Experiences in Subaqueous Concrete Work, Henry R. Lordly. Cornell Civil Engr., vol. 28, no. 6, March 1920, pp. 254–263, 4 figs. Successful instances of placing concrete under water are related. It is held there is no further need of building expensive cofferdams.

CONCRETE, REINFORCED

Wood Reinforcement. Reinforcing Concrete with Wood (Le béton armé de bois). Génie Civil, vol. 77, no. 20, Nov. 13, 1920, pp. 394–396, 8 figs. Methods of reinforcing developed in experiments.

CONDENSERS, STEAM

Selection. Application of Steam Condensers, F. A. Burg. Elec. Jl., vol. 17, no. 12, Dec. 1920, pp. 583–587, 6 figs. Factors bearing on selection of type of condenser.

Surface. Surface Condensers, Luther D. Lovekin. Twenty-eighth General Meeting, Soc. Naval Architects & Mar. Engrs., Nov. 11 and 12, 1920, no. 7, 5 pp., 10 figs. Progress in design of surface condensers as applied to power plants in U. S. Navy Ships.

CONVEYORS

Cable. The Roe Cable Conveyor, George Frederick Zimmer. Eng., vol. 110, no. 2864, Nov. 19, 1920, pp. 665–667, 37 figs. partly on supp. plate. Wire rope conveyor for medium distances, designed by J. Pearce Roe.

Combined Skip Hoist and Conveyor. Combined Skip-Hoist Elevator and Conveyor, George Frederick Zimmer. Eng. and Indus. Management, vol. 4, no. 19, Nov. 4, 1920, pp. 597–598, 5 figs. Device patented by Warren Travell, of Exeter Machine Works, New York City. It combines skip hoist with band conveyor and with tipping trolley on wheels.

Pneumatic. Pneumatic Conveyors of Fine Materials. Contract Rec., vol. 34, no. 51, Dec. 22, 1920, pp. 1218–1220. Examples of English installations for the pneumatic lifting and conveying of coal and other materials.

CORE OVENS

Electrically Heated. Core Baking in Electrically Heated Ovens, J. L. Jones, Iron Age, vol. 106, no. 22, Nov. 25, 1920, pp. 1385–1387, 3 figs. Results of comparative tests of electric and fuel heated core ovens. New Westinghouse thermostat control.

Electrifying the Foundry Core Room, J. L. Jones. Elec. World, vol. 76, no. 25, Dec. 18, 1920, pp. 1203–1204, 3 figs. Cores baked in electrically heated ovens shown to have 50 to 200 per cent greater strength than those baked in fuel-fired ovens.

CORK

Substitute for. A Substitute for Cork. Commerce Reports, no. 283, Dec. 2, 1920, p. 978. Turf treaded by special patented process developed by chemical works at Bruenn-Koenigsfeld, Prague.

CORROSION

Iron and Steel. Experiments on the Corrosion of Iron and Steel, William D. Richardson. Can. Chem. Jl., vol. 4, no. 11, Nov. 1920, pp. 299–307. Passivity of iron as oxidation phenomenon. (Concluded.)

COST ACCOUNTING

Factory. Factory Costs, L. T. Konopak. Jl. of Accountancy, vol. 30, no. 5, Nov. 1920, pp. 329–337. Describes cost system designed for factory manufacturing transmissions, and forms provided for reporting the various transactions of factory designed to facilitate handling clerical work in a routine manner with least consumption of time.

COSTS

Relation to Selling Prices. The Determination of Costs and Their Relation to Profit and Selling Prices. Eng. & Indus. Management, vol. 4, no. 23, Dec. 2, 1920, pp. 713–715. Predetermination of prices.

CRANES

Floating. Two-Hundred Ton Mammoth Floating Crane at Gusto Shipyard, Schiedam, Holland [Grue Flottante "Mammoth," de 200 tonnes, des Chantiers Gusto, de Schiedam (Hollande)]. Génie Civil, vol. 77, no. 19, Nov. 6, 1920, pp. 365–367, 3 figs. Crane can lift 200 tons 52 m. high above surface of water. Radius of action is 34 m.

CRANKSHAFTS

Case-Hardening. Case-Hardening Process for Crankshafts Successfully Developed, Norman G. Shidle. Automotive Industries, vol. 43, no. 21, Nov. 18, 1920, pp. 1016–1019, 5 figs. Process developed from tests made by H. H. Franklin Manufacturing Co.

CRIPPLES

Artificial Limbs. The Muscular Strength in an Amputated Arm and Its Utilization (Die Muskelkräfte im Innern des amputierten Armes und ihre Nutzbarmachung), G. Schlesinger and K. Meyer. Werkstattstechnik, vol. 14, no. 17, Sept. 1, 1920, pp. 457–463, 24 figs. Results of experiments carried out at the Charlottenburg Testing Inst. for Substitute Limbs. Abstract of report of investigations of about 30 men who had undergone the Sauerbruch operation, and of a large number of artificial hands and arms with apparatus especially constructed therefore, description and illustrations of which are given.

CUPOLAS

Charges, Determining. Method for Determining Cupola Charges, H. L. Campbell. Foundry Trade Jl., vol. 22, no. 227, Nov. 1920, pp. 856–857, 1 fig. Chart for determining mixtures.

CYLINDERS

Automobile Engines. How Cylinders are Made in England, H. Cole Estep. Foundry, vol. 48, no. 23, Dec. 1, 1920, pp. 933–939, 13 figs. Standardization of operations and extensive use of molding machines have aided quantity production.

D

DIES

Double-Flanged Shell. Dies for Double-Flanged Shell, J. Bingham. Machy. (Lond.), vol. 17, no. 424, Nov. 11, 1920, pp. 176–178, 10 figs. Procedure for designing drawing dies.

DIESEL ENGINES

Busch-Sulzer. Diesel Engines in a Modern Flour Mill. Power, vol. 52, no. 21, Nov. 23, 1920, pp. 808–810, 5 figs. Busch-Sulzer and Fulton-Tosi types used.

Fuel Injection. Air-Injection or Mechanical-Injection, J. L. Chaloner. Motorship, vol. 5, no. 12, Dec. 1920, pp. 1084–1085, 8 figs. Technical study of fuel injection in Diesel engines. (To be continued.)

28 figs. Experiments carried out at British Admiralty Engineering Laboratory in connection with development of high-speed engine for naval purposes. Both solid-injection and air-injection systems were taken up.

Marine. Building Diesel Marine Engines for Merchant Vessels—I, Fred B. Jacobs. Mar. Rev., vol. 50, no. 12, Dec. 1920, pp. 640–647, 12 figs. Manufacturing methods at Busch-Sulzer Bros.-Diesel Engine Co., St. Louis.

Opposed-Piston. British Admiralty Experiments with Diesel Engines—III, C. J. Hawkes. Motorship, vol. 5, no 12, Dec. 1920, pp. 1086, 3 figs. Tests on Doxford opposed-piston submarine Diesel engine. (Concluded.)

DRILLING

Automobile Plants. Multiple Drilling in Automobile Plants. Machy. (Lond.), vol. 17, no. 426, Nov. 25, 1920, pp. 225–229, 10 figs. Multiple-spindle drilling machines.

Deep-Hole. Some Experiences in Deep-Hole Drilling, Charles J. Starr. Am. Mach., vol. 53, no. 23, Dec. 2, 1920, pp. 1023–1026, 9 figs. Requirements of Drill.

DRILLING MACHINES

Multiple-Spindle. A Multiple Spindle Drilling Machine, G. L. Bohannon. Boiler Maker, vol. 20, no. 11, Nov. 1920, pp. 321–323, 5 figs. Machine built by Thomas Spacing Machine Co., Pittsburgh, Pa. Chief feature is chain drive which gives direct pull on spindles and is said to eliminate power losses.

Semi-Automatic. A New Type of Semi-Automatic Drilling Machine. Machy. (Lond.), vol. 17, no. 423, Nov. 4, 1920, pp. 139–140, 5 figs. Drill is fed to work by automatic cam motion. Feature is tilting work table whereon two work-holding fixtures may be mounted, each being brought under drill spindle in turn. Machine is manufactured by S. Ratcliffe, Ltd., Manchester, England.

Universal. 5-Ft. Universal Radial Drilling Machine. Eng., vol. 110, no. 2862, Nov. 5, 1920, pp. 600–601, 6 figs. Arm can be swiveled for angle drilling and spindle swiveled on saddle. Manufactured by Niles-Bement-Pond Co., New York.

DRILLS

Electric. Portable Electric Tools, Machy. (Lond.), vol. 17, no. 427, Dec. 2, 1920, pp. 250–252, 7 figs. Electric drills.

Twist. Proper Care of Twist Drills as a Means of Economy, G. P. Blackiston. Boiler Maker, vol. 20, no. 12, Dec. 1920, pp. 360–361. Tables showing speeds and feeds for carbon and high-speed drills.

DROP FORGING

English Plant. A Modern Drop Forging Plant. Eng. Production, vol. 1, no. 13, Dec. 1920, pp. 483–486, 8 figs. Description of Abbey Works Forge of Clayton & Shuttleworth, Lincoln, England.

Practice. Drop Forging, J. H. Moore. Can. Machy., vol. 24, no. 23, Dec. 2, 1920, pp. 485–489, 9 figs. Examples of drop-forging practice, including axles and crankshafts.

DYE HOUSES

Organization and Construction. Organization and Construction of Dye Houses, A. W. Benoit. Mech. Eng., vol. 42, no. 12, Dec. 1920, pp. 673–674 and p. 706, 2 figs. Machinery organization, location, construction, ventilation and piping of dye houses considered from engineering viewpoint.

DYNAMOMETERS

Farm Tractors. National Physical Laboratory Traction Dynamometer for Agricultural Tractors, J. H. Hyde. Eng., vol. 110, no. 2865, Nov. 26, 1920, pp. 693–694, 7 figs. Apparatus consists of cylinder and plunger, former being attached to drawbar of tractor, and latter through links to plow. Pull on coupling sets up pressure in oil confined in cylinder, at flexible hydraulic tube.

E

EDUCATION, INDUSTRIAL

Ford Institute of Technology. Linking Education With Factory Costs—III, T. P. Hickey. Factory, vol. 25, no. 11, Dec. 1, 1920, pp. 1726–1730, 8 figs. Organization of Ford Inst. of Technology.

ELECTRIC DRIVE

See ICE PLANTS, Electrically Driven; ROLLING MILLS, Electrically Driven.

ELECTRIC FURNACES

Booth. Booth Rotating Electric Brass Furnace, Carl H. Booth. Iron Age, vol. 106, no. 23, Dec. 2, 1920, pp. 1463–1464, 2 figs. Records recently made on 500 lb. rotating electric furnace at plant of Enterprise Brass Works, Muskegon, Mich. Paper read before Am. Foundrymen's Assn.

Combustion vs. Electric vs. Combustion Furnaces for Low Temperatures, Frank W. Brooke and George P. Mills. Chem. and Metallurgical Eng., vol. 23, Nov. 24, 1920, pp. 1008–1010. Electric furnaces are found to have advantage in temperature control, reliable and permanent source of heat and maintenance. Cost of power is counterbalanced by economy in space, auxiliaries, and operation, while quality of product is greatly enhanced.

Commercial Types. The Electric Melting Furnace, Joseph W. Richards, F. W. Brooke, R. D. Thomas,

Linings. Linings for Electric Furnaces, R. M. Howe. Iron Trade Rev., vol. 67, no. 23, Dec. 2, 1920, pp. 1541–1543. Survey is made of nine materials used as refractories for electric units. Physical characteristics compared. Fusion points are lowered by pressure. Silica and magnesia tend to spall.

Metal Industries, Use in. The Present Status of the Electric Furnace in the American Metal Industries, Robert M. Keeney. Chem. & Metallurgical Eng., vol. 23, no. 20, Nov. 17, 1920, pp. 980–984. Present technology and future possibilities of electric furnace as applied in manufacture of synthetic cast iron, steel, steel castings, ferroalloys and in heat treating, brass melting and smelting of nonferrous ores. Paper read before Nat. Elec. Light Assn.

Motion of Liquid by "Motor Effect." Nature and Explanation of the "Motor Effect" in the Ajax-Wyatt Furnace, E. F. Northrup. Jl. Franklin Inst., vol. 190, no. 6, Dec. 1920, pp. 817–834, 4 figs. When high-tension current, direct or alternating, flows in a liquid conductor, motions of liquid of considerable magnitude are always produced. Article develops formula for calculating mechanical forces which arise by interaction of triangular circuit carrying current upon short section of circuit. Numerical results are tabulated and values of forces are given in chart.

Refractories for. Refractories For Electirc Furnaces, R. M. Rowe. Foundry, vol. 48, no. 22, Nov. 15, 1920, pp. 911–913. Survey of different materials and tables of their physical characteristics. Paper read before Elec. Furnace Assn.

Repelling Arc. Electric Furnace with a Repelling Arc. Iron Age, vol. 106, no. 24, Dec. 9, 1920, pp. 1556–1557, 4 figs. Electric furnace for steel and nonferrous operations developed by Industrial Electric Furnace Co., Chicago. When current flows electrodes are forced apart, thus drawing arc.

Steel Manufacture. English and American Types of Electric Iron and Steel Furnaces Compared, John B. C. Kershaw. Iron & Coal Trades Rev., vol. 101, no. 2750, Nov. 12, 1920, pp. 637–640 and 655–658, 16 figs. Based on records of operation at steel works.

ELECTRIC LAMPS, MERCURY-ARC

Cooper Hewitt. The Cooper Hewitt Quartz Lamp and Ultra-Violet Light, L. J. Buttolph. Gen. Elec. Rev., vol. 23, no. 11, Nov. 1920, pp. 909–916, 8 figs. Summary of latest developments of compilation of related technical data.

ELECTRIC LOCOMOTIVES

Driving Gears. Driving-Gear Arrangements in Electric Locomotives (Treibwerksanordungen bei elektrischen Lokomotiven), A. Marschall. Zeit. fur Dampfkessel u. Maschinenbetrieb, vol. 43, no. 39, Sept. 24, 1920, pp. 299–302, 3 figs. Discussion of various types, including the Brown, Boveri & Cie and the Tschantz driving gear, but with special consideration of the latest Lentz construction, with which it is said to be possible to render gear ratio between motor- and driving-wheel shaft variable, as with automobile gears.

ELECTRIC WELDING

Development. Practical Applications of Electric Welding, F. P. Vaughan. Jl. Eng. Inst. Canada, vol. 3, no. 12, Dec. 1920, pp. 556–564, 5 figs. Survey of electric welding methods, resistance, carbon arc, metallic arc and quasi-arc; methods of application, tables of power consumption, etc.; training welder, protection devices.

Electropercussive. Recent Developments in Electro-Percussive Welding, Douglas F. Miner. Welding Engr., vol. 5, no. 11, Nov. 1920, pp. 27–28 and 32, 7 figs. Describes apparatus used, which consists essentially of device for producing a percussive engagement of parts to be welded, practically simultaneous with discharge of electrical energy. Gives examples of electropercussive welding and photomicrographs.

ELECTRIC WELDING, ARC

Overhead. Overhead Arc Welding—Theory and Practice, O. H. Eschholz. Power, vol. 52, no. 20, Nov. 16, 1920, 776–780, 11 figs. Also results of tensile tests made on sections cut from overhead welds.

EMPLOYMENT MANAGEMENT

Psychotechncal Tests. Apparatus for Adaptability Tests (Apparate fur Eignungsuntersuchungen), R. Thun. Betrieb, vol. 3, no. 1, Oct. 10, 1920, pp. 24–29, 7 figs. Gives certain guiding rules which should be taken into consideration in development of apparatus and describes various apparatus.

Psychotechnical Adaptability Tests (Psychotechnische Eignungsprüfungen), H. Heilandt. Betrieb, vol. 3, no. 1, Oct. 10, 1920, pp. 16–21, 12 figs. Describes method of examination employed in the admission of industrial apprentices in the works school of the German General Electric Co.'s factories in Berlin.

The Reliability of the Psychological Adaptability Tests (Bewährung der psychologischen Eignungsprüfungen), H. Rupp. Betrieb, vol. 3, no. 1, Oct. 10, 1920, pp. 1–8, 7 figs. It is shown that the reliability of an adaptability test can be accurately determined and what degree of reliability according to described method can be ascribed to the most important tests so far developed. Points out certain requirements which are necessary for the proper application and improvement and extension of tests.

ENGINEERING SOCIETIES

Relationship to Public Service. Some Phases of Relationship of Engineering Societies to Public Service, Herbert Hoover. Jl. Am. Inst. Elec. Engrs., vol. 39, no. 12, Dec. 1920, pp. 1073–1075. Address before Federated American Engineering Societies.

ENGINEERS

Registration. Report of Ontario Committee on Legislation. Can. Engr., vol. 39, no. 26, Dec. 23, 1920, pp. 631–635. Text of bill for official registration of engineers, proposed by Ontario Advisory Committee.

Remuneration. Manitoba Engineers Pledged to Salary Schedule. Can. Engr., vol. 39, no. 20, Nov. 11, 1920, pp. 505–508. Work being done by Remuneration Committee of Manitoba Branch, Engineering Institute of Canada, in enforcing Salary Committee's recommendations. Branch has decided that "any engineer who fails to receive salary adequate to his class as recommended by the Remuneration Committee will be assisted by the Engineering Institute of Canada to obtain other employment at adequate remuneration and will receive the moral, and, if necessary, financial support of all other engineers in the province." Classification of engineers and schedule of salaries prepared by Salary Committee are included.

ENGINEHOUSES

Electrical Equipment. Electrical Equipment of New Engine Terminal. Ry. Elec. Engr., vol. 11, no. 12, Dec. 1920, pp. 437–439, 4 figs. Motors used in machine shops and on turntable at terminal on New York Central at Minerva, Ohio.

F

FACTORIES

Layout. Economy of Horizontal Space by the Machine Layout. J. Edward Schipper. Automotive Industries, vol. 43, no. 20, Nov. 11, 1920, pp. 964–967, 6 figs. Description of Holley carburetor factory. Light work is arranged on continuous table with machines spaced by requirements of workmen.

FACTORY MANAGEMENT

See INDUSTRIAL MANAGEMENT

FANS, CENTRIFUGAL

Design. The Design and Construction of Fans—I, F. G. Whipp. Mech. World, vol. 68, no. 1768, Nov 19, 1920, pp. 354–355, 3 figs. Calculation of efficiencies of propeller fans.

FATIGUE

Industrial. An Experiment with Rest Pauses, J Loveday. Eng. & Indus. Management, vol. 4, no 23, Dec. 2, 1920, pp. 716–718. Experiment in British shoe factory. Double presses were worked with team of three girls each operative working 40 min. in each hour and resting 20 min. Output was increased from 57 to 75 per cent.

FLIGHT

Man-Power. The Problem of Flight with Man-Power (Das Problem des MS-Fluges), Rudolph Waschmann. Luftfahrt, vol. 24, no. 9, Sept. 2, 1920, pp. 133–135. Discussion of R. Nimführ's new but already tested, theory of the dynamic flight, according to which, the pressure of air is utilized as the supporting force. Describes how a constant atmospheric pressure wave is generated on which the airplane sails with much less consumption of power than would be the case with propeller drive. Describes how with the Nimfuhr flight theory, gravity can be overcome with employment of a single man power (equivalent to $^1/_5$ hp.).

FLYING BOATS

Controls. Sand Test of Flying Boat Controls. Aviation, vol. 9, no. 11, Nov. 29, 1920, pp. 350–352, 7 figs. Account of tests on controls of aeromarine model 40 flying boat.

FOREMEN

Training of. Adopt Methods to Develop Foremen, M. C. Evans. Foundry, vol. 48, no. 24, Dec. 15, 1920, pp. 1001–1004. Detailed description of foreman's development course which was conducted during six months of last fall and winter at plants of International Harvester Co. Paper read before American Foundrymen's Association.

FORGING

Gas for. Gas for Forging. Gas Industry, vol. 20 no. 11, Nov. 1920, pp. 257–260. Requirements and advantages.

Why Gas Excels for Forging. Gas Rec., vol. 18, no. 9, Nov. 10, 1920, pp. 67–69. Experience of Henry L. Doherty Co.

Norfolk Navy Yard Shop. Forge Shop at the Norfolk Navy Yard, J. S. Glover. Am. Drop Forger, vol. 6, no. 11, Nov. 1920, pp. 555–558, 3 figs. Size, layout and equipment of plant. Compressed air used to operate hammers. Design of forges and oil atomizers. Butt-weld machine. Reclaiming propellers.

FOUNDRIES

Air Furnace for. Air Furnace Iron for Big Castings, H. E. Diller. Foundry, vol 48, no. 24, Dec. 15, 1920, pp. 973–977, 8 figs. Air furnace used in

one of foundries of Westinghouse Electric & Mfg. Co.

Equipment. Choosing Correct Plant Equipment, Joseph J. Wilson. Foundry, vol. 48, no. 24, Dec. 15, 1920, pp. 985–988. Selection of machines and appliances exemplified in case of foundry of Saginaw Products Co., Saginaw, Mich. Paper read before National Founder's Association.

Germany. The G. Krautheim Foundry Plants in Chemnitz for Production of Cast Steel, Malleable and Gray Iron Castings (Die Stahl-, Temper- und Graugiesserei-Anlagen der Firma G. Krautheim in Chemnitz.) Stahl u. Eisen, vol. 40, nos. 39 and 43, Sept. 30 and Oct. 28, 1920, pp. 1293–1300 and 1443–1448, 22 figs. Description of works employing 1600 men, including original plant in Chemnitz-Altendorf, in which malleable and gray-iron castings are produced, and the new steel foundry in Chemnitz-Borna, with notes of arrangement of plant, small Bessemer plant, the open-hearth furnaces, the electric steel furnaces, the cleaning shop, molding, shop, etc.

Organization. Training Executives for Foundries, Bruce W. Benedict and Robert E. Kennedy. Foundry, vol. 48, no. 22, Nov. 15, 1920, pp. 903–907, 5 figs. Suggested organization for foundries. Shop training course at University of Illinois. Paper read before Am. Foundrymen's Assn.

[See also CORE OVENS.]

FOUNDRY EQUIPMENT

Developments. Foundry Equipment in Modern Plants, Joseph J. Wilson. Iron Age, vol. 106, no. 22, Nov. 25, 1920, pp. 1392–1397, 10 figs. Survey of recent developments.

FUELS

Colloidal. The Case for Colloidal Fuel, Lindon W. Bates. Chem. Age (Lond.), vol. 3, no. 75, Nov. 20, 1920, pp. 558–559. Economic advantages. Paper read before Instn. Petroleum Technologists.

[See also OIL FUEL; PULVERIZED COAL; RESEARCH, Liquid Fuels.]

FURNACES

Heat Flow Through Walls. Heat Flow Through Furnace Walls—II, E. F. Davis. Trans. Am. Soc. for Steel Treating, vol. 1, no. 2, Nov. 1920, pp. 128–140, 17 figs. Experimental measurements.

FURNACES, BOILER

Forced-Draft. Forced Draft Furnaces (Unterwindfeuerungen), L. Schmitt. Tonindustrie-Zeitung, vol. 44, no. 106, Sept. 7, 1920, pp. 938–939. Discussion of the relative value of forced-draft furnaces and steam-jet blowers, writer favoring the former.

Recommendations for the Development of Forced-Draft Furnaces (Vorschläge für den Ausbau der Unterwindfeuerungen), E. Nies. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 43, no. 39, Sept. 24, 1920, pp. 297–299. Writer makes following suggestions: (1) The free surface of grate with use of under-grate draft should be reduced to from 4 to 6 per cent as against 35 to 40 per cent in plain horizontal grates; (2) grate bars and plates should be inserted accurately, and free surface of grate should not be changed, (3) in external furnaces the circulation of air through the side grate bars should be reduced; (4) in flue boilers, end of grate should be provided with a plate upon which the red coals can be shoved while cleaning the fire.

The "Turbine" Forced-Draught Furnace. Eng., vol. 110, no. 2863, Nov. 12, 1920, pp. 639–640, 8 figs. Arrangement consists of series of troughs which lie side by side and form base of furnace. Front of each trough forms air injector and is fitted with steam jet.

FURNACES, ELECTRIC

See ELECTRIC FURNACES.

FURNACES, HEATING

Labor-Saving Features. Heating Furnaces and Annealing Furnaces, W. Trinks. Blast Furnace & Steel Plant, vol. 8, no. 12, Dec. 1920, pp. 671–675, 12 figs. Labor saving features of different types of furnaces.

FURNACES, HEAT-TREATING

Electric Heaters. Electric Heaters for Heat Treating Furnaces—II, H. O. Swoboda. Am. Drop Forger, vol. 6, no. 11, Nov. 1920, pp. 540–543, 9 figs. Carbon and graphite resistors are used with success in several types of furnaces. Furnace charge is used as heater in special cases. Temperature control.

Oil-Burning. Annealing and Heat Treatment Furnaces, James E. Wilson. Jl. Engrs. Club of Phila., vol. 37–12, no. 192, Dec. 1920, pp. 488–489. Design, regulation of cost of oil-burning steel heat-treating furnaces.

FURNACES, OPEN HEARTH

Waste-Heat Boilers. Application of Waste Heat Boilers to Open Hearth Furnaces, Thomas R. Tate. Jl. Engrs. Club of Phila., vol. 37–12, no. 192, Dec. 1920, pp. 485–487. Design of proper size and type boiler for any installation. Paper read before Assn. Iron & Steel Elec. Engrs.

G

GAGES

Indicating. Indicating and Contour Gauges. Machy. (Lond.), vol. 17, no. 427, Dec. 2, 1920, pp. 259–263, 11 figs. Classification and description.

Limit. Limit Gauges. Eng., vol. 110, no. 2863, Nov. 12, 1920, pp. 643–644. Developments in standardization.

Limit Gauging, Richard T. Glazebrook. Jl. Instn. Mech. Engrs., no. 8, Dec. 1920, pp. 1075–1088, 5 figs. Diagram of grades of fit, and chart of limits. (To be continued.)

Limit Plug. Quantity Production of Combination Limit Plug Gauges. Machy. (Lond.), vol. 17, no. 423, Nov. 4, 1920, pp. 151–153, 4 figs. Combination limit plug gage introduced by Taft-Pierce Mfg. Co., Woonsocket, R. I.

Screw-Thread. Hardening Screw Gauges with Least Distortion, Wilfred J. Lincham. Can. Machy., vol. 24, no. 22, Nov. 25, 1920, pp. 472–476, 14 figs. Method developed at Goldsmith's College, London.

GAS ENGINES

Castings. Problems Encountered in Gas Engine Castings, Pat Dwyer. Foundry, vol. 49, no. 24, Dec. 15, 1920, pp. 980–983, 9 figs. Casting practice at plant of Rathbun-Jones Engineering Co., Toledo, Ohio.

Valveless. The Development of Two-Stroke High-Power Gas Engines (Weiterentwicklung der Zweitakt-Grossgasmaschinen), W. Bertram. Stahl. u. Eisen, vol. 40, no. 40, Oct. 7, 1920, pp. 1335–1340 and (discussion) pp. 1340–1341, 5 figs. Describes construction and operation of new valveless gas engine of the Dahlbrucher Machine Construction Corp'n. and gives operating results of engine reconstructed according to this type.

GASOLINE

Production of. Production of Gasoline. Power, vol. 52, no. 20, Nov. 16, 1920, pp. 788–789. Statistics of refinery production of gasoline for period of sixteen years, 1904 to 1919, inclusive. Advance publication of Bureau of Mines Bulletin No. 191.

Specifications. Aviation Gasoline Specifications and Methods for Testing. Air Service Information Circular, vol. 1, no. 46, Aug. 30, 1920, 8 pp. 3 figs. Specifications cover three grades of gasoline known as domestic aviation gasoline, export gasoline and fighting gasoline. Distillation test is required for determining grade of gasoline. Procedure and details of manipulation in conducting distillations are explained.

GASOLINE ENGINES

Two-Cycle. The Two-Cycle Lutin Motor (Le moteur à 2 temps Lutin), H. Petit. Vie Automobile, vol. 16, no. 717, Nov. 10, 1920, pp. 420–421, 3 figs. Piston is enlarged at base and fits in larger cylinder. Lower element of piston is used for compressing mixture before charging into upper cylinder.

GEARS

Bevel. A New Development in Bevel Gear Cutting. Machy. (Lond.), vol. 17, no. 425, Nov. 18, 1920, pp. 199–203, 8 figs. Attachments applicable to ordinary shaping machine.

Design. Graphical Method for Designing a Set of Complex Gears (Méthode graphique par anamorphose pour l'établissement des trains d'engrenages complexes), Luc Denis. Vie Technique et Industrielle, vol. 1, no. 9, June 1920, pp. 221–222, 3 figs. Examples. (Concluded.)

Involute. Involute Teeth, Richard Gardner. Eng., vol. 110, no. 2864, Nov. 19, 1920, pp. 659–660, 2 figs. Design formulas.

Machining Blanks. Machining Friction Gear Blanks and Friction Cones, J. H. Moore. Can. Machy., vol. 24, no. 17, Oct. 21, 1920, pp. 371–373, 8 figs. Examples of work performed according to practice of Foster Machine Co., Elkhart, Ind.

Pitch-Measuring Machine. The Wickman Pitch Measuring Machine. Automobile Engr., vol. 10, no. 145, Dec. 1920, p. 481, 4 figs. Machine is designed to measure tooth spacing at pitch line as well as concentricity of pitch circle with bore.

Reduction. See REDUCTION GEARS.

Spur. Backlash Standards for Spur Gears, Charles H. Logue. Am. Mach., vol. 53, no. 23, Dec. 2, 1920, pp. 1040–1041, 2 figs. Formula for determining proper backlash for spur gears, and tables computed from formula.

Welding of. The Art of Welding Gears and Pinions, F. H. Sweet. Blast Furnace & Steel Plant, vol. 8, no. 12, Dec. 1920, pp. 684–685. Advisability of welding each tooth separately or of welding several teeth en bloc. Selection of proper welding tip and filler rod.

GIRDERS

Design. Reduction of Girder and Column Live Loads, C. R. Young. Can. Engr., vol. 39, no. 23, Dec. 2, 1920, pp. 565–569, 2 figs. Principle of discounting improbable live loads generally observed. Intensity of floor loads for buildings varies inversely as tributary area. Review of various reduction rules. New specification suggested.

Stresses in. Notes on Impact, F. W. Gardiner. Proc. Am. Soc. Civil Engrs., vol. 46, no. 9, Nov. 1920, pp. 976–977. Relation between static and dynamic stresses in girder spans for smooth rolling loads. It was found that for speeds that obtain in railroad practice dynamic effect of smooth rolling loads may be neglected; dynamics increment of stress for single load for critical speed is given as 31.8 per cent. (Abstract.)

GLUES

See AIRCRAFT CONSTRUCTION MATERIALS, Casein Glue.

H

HANDLING MATERIALS

Railway Shops. Handling Material in Railway Shops, Frank A. Stanley. Am. Mach., vol. 53, no. 21, Nov. 18, 1920, pp. 953–954, 7 figs. Typical labor-saving devices.

HANGARS

Design. Hangars for Dirigibles and Their Accessories (Les gares de dirigeables et leurs accessoires), M. J. Sabatier. Aéronautique, vol. 2, no. 14, July 1920, pp. 55–60, 12 figs. Scheme of turning German man hangars around on base.

HARDNESS

Instruments for Testing. Rapid Measurement of Hardness and Resilience of Metals (Mesures rapides de la dureté et de la résilience des metaux), S. Boisthorel. Nature (Paris), no. 2427, Oct. 9, 1920, pp. 230–234, 10 figs. Guillery portable apparatus for use in workshops.

Measurement of. The Measurement of the Hardness of Metals, Hugh O'Neill. Mech. World, vol. 68, no. 1769, Nov. 26, 1920, pp. 383–384, 2 figs. Classification of methods. Discussion of their relative advantages and disadvantages. (To be continued.) Paper read before Sheffield University Metallurgical Soc.

HEATING

Electric. Economic Heating by Means of Hydroelectric Energy (La produzione economica del calore mediante l'energia idroelettrica), C. Baulino. L'Elettrotecnia, vol. 7, no. 18, June 25, 1920, pp. 318–320, 1 fig. Scheme involving passage of heat at low temperature into high temperature by utilization of mechanical energy.

HEAVY-OIL ENGINES

Pistons. Piston and Rings for Heavy Oil Engines, W. D. Forbes. Mar. Eng., vol. 25, no. 12, Dec. 1920, pp. 1002–1003, and p. 1013. Solid and forged pistons discussed. Method of forming piston rings from castings. Assembling forged pistons.

HELICOPTERS

Hewitt-Crocker. The Hewitt-Crocker Helicopter, Francis Bacon Crocker. Aerial Age, vol. 12, nos. 11 and 12, Nov. 22 and 29, 1920, pp. 295–297, 4 figs., and 323–325, 1 fig. Machine comprises upper propeller revolving in normally horizontal plane and propeller in parallel plane 7 ft. below. Each propeller is 51 ft. in diameter. Propellers revolve in opposite directions.

Problem of. The Problem of the Helicopter, Louis Damblanc. Aeronautics, vol. 19, nos. 371 and 372, Nov. 25 and Dec. 2, 1920, pp. 379–381 and 392–394. Also Flight, vol. 12, no. 48, Nov. 25, 1920, pp. 1219–1223, 10 figs. Comparative study of two proposed types of helicopters, (1) machine with single axis and (2) that with separate axis. Paper read before Royal Aeronautical Soc.

Propellers of. Note on Supporting Propellers (Note sur les hélices sustentatrices), M. Lamé. Aérophile, vol. 28, nos, 17–18, Sept. 1–15, 1920, pp. 269–270, 1 fig. Characteristics of propeller which would permit by its free rotation safe falling of helicopter.

HOISTING ENGINES

Emergency Governor. An Emergency Governor with Hoist Recorder Gives Data on Safety and Efficiency, G. F. Royer. Coal Age, vol. 18, no. 22, Nov. 25, 1920, pp. 1079–1084, 4 figs. Emergency governor for control of clutch-drum hoisting engines.

HOISTS

Drum Design. Calculation of Stresses in Winding-Drum Flanges. Am. Mach., vol. 53, no. 25, Dec. 16, 1920, pp. 1130–1131, 2 figs. Diagrams of forces acting.

Rational Design of Hoisting Drums, Everett O. Waters. Mech. Eng., vol. 42, no. 12, Dec. 1920, pp. 675–679, 9 figs. Theoretical formula is deduced for total pressure against drum flange caused by winding-on of rope to given depth and under given initial tension. Two other formulas are also deduced, which relate total pressure to flange thickness and maximum allowable tensile and shearing stresses in material. By means of these formulas flange of usual mushroom type may be designed to withstand safely pressure of rope wound upon drum.

HOUSING

England. Concrete Cottage Building. Concrete and Constructional Eng., vol. 15, no. 11, Nov. 1920, pp. 737–742, 5 figs. Meanwood housing scheme, Leeds.

Industrial. Solving the Housing Problem, Herbert Hoover, Leslie H. Allen, Philip W. Blake and W. Gibbs Astle. Indus. Management, vol. 60, no. 6, Dec. 1920, pp. 425–436, 8 figs. Why industrial executives must do it and how it is being done.

Legislation in England. The Garden City and English Housing Laws, Leonard S. Smith. Eng. and Contracting, vol. 54, no. 21, Nov. 24, 1920, pp. 510–513, 2 figs. Resolutions adopted at World Congress on Housing and Town Planning held in London, June, 1920.

Schemes. Housing and Community Planning, John Irwin Bright. Jl. Am. Inst. of Architects Supp. 8 pp., 4 figs. Scheme developed by Committee on Community Planning of American Institute of Architects.

HYDRAULIC TURBINES

High-Head. Turbines for Niagara's High-Head Plant. Iron Age, vol. 106, no. 23, Dec. 2, 1920, pp. 1453–1457, 11 figs. Normal operating capacity will be 52,500 hp. and net effective head, 305 ft.

das gesamte Turbinenwesen, vol. 17, no. 27, Sept. 30, 1920, pp. 318-320, 5 figs. Writer describes his new regulation for full-jet turbines which consists of a changeable width of rim for centrifugal and inward radial-flow turbines; and his hydraulic regulator which is equipped with two separate regulating valves, one for opening and the other for closing main inlet. Abstract of address delivered before Austrian Assn. of Engrs. & Architects.

Theory of. New Analytical Theory of Water Turbines. Mech. Eng., vol. 42, no. 12, Dec. 1920, pp. 689-692, 1 fig. Formulas combining various elements of turbines. Translated from Technique Moderne.

HYDROELECTRIC PLANTS

Abitibi River. Twin Falls Development on Abitibi River, Harold L. Trotter. Can. Engr., vol. 39, no. 25, Dec. 16, 1920, pp. 605-609, 9 figs. New plant for Abitibi Power & Paper Co. to have five 6000-hp. vertical turbines. Concrete dam across river raises headwater 57 ft. Reinforced-concrete power house. Description of construction methods and plant.

Auxiliary Equipment. Efficiency of Installing Energy Accumulators of Small Output in Hydroelectric Central Stations (Sur l'efficiacité de l'adjonction de systèmes accumulateurs d'énergie même à bas rendement aux centrales hydrauliques), A. Della Riccia. Revue générale de l'électricité, vol. 8, no. 17, Oct. 23, 1920, pp. 555-564, 7 figs. Special reference is made to installation of a heat accumulator suggested by M. Del Proposto, which consists of a set of boilers heated by the flow of hot oil, in combination with ordinary water-tube boiler. Oil is heated electrically in special cylinder. Steam from system operates turbine directly coupled with generator.

Brazil. Development of Hydroelectric Plants. Commerce Reports, no. 43b, Nov. 24, 1920, p. 10. Developments in Brazil.

France. The Eget Plant of the French Southern Railway (L'usine d'Eget de la Compagnie des Chemins de Fer du Midi). M. Barbillion. Industrie Électrique, vol. 29, no. 678, Sept. 25, 1920, pp. 345-350, 7 figs. Details of conduits. (Concluded.)

The Hydroelectric Plants at Rioupéroux (L'usine de Rioupéroux), M. Barbillion. Industrie Électrique, vol. 29, no. 679, Oct. 10, 1920, pp. 363-370, 19 figs. Hydroelectric central station producing single-phase current at 8200 volt and three-phase current at 63,000 volt. Power is supplied to metallurgical industries in neighborhood.

Hydrographic Studies. Hydrographic Study Preliminary to Utilizing the Water Power of a Mountain Basin (Étude hydrographique et aménagement d'un bassin montagneux), G. Malforn. Électricien, vol. 36, no. 1262, Oct. 15, 1920, pp. 433-436, 3 figs. Plan for utilization of basin in Italian Alps. (To be continued.)

Ice Protection. Ice Protection for Hydroelectric Plant, John S. Carpenter. Power Plant Eng., vol. 24, no. 23, Dec. 1, 1920, pp. 1125-1126, 2 figs. Methods of deflecting ice jams.

Kerckhoff Development. Kerckhoff Power Development—A western Achievement, J. M. Buswell. Power, vol. 52, no. 24, Dec. 14, 1920, pp. 926-934, 14 figs. Project includes concrete, constant-angle arch dam across main San Joaquin River; 18 x 18 ft. unlined pressure tunnel 16,875 ft. long; steel triple-penstock line; reinforced-concrete power house, housing three 15,000-hp. vertical-shaft turbines to operate under head of 315 to 340 ft. and directly connected to 14,200-kva. vertical-shaft generators.

New Brunswick. Hydro-Electric Power Development in New Brunswick, C. O. Foss. Can. Engr., vol. 39, no. 23, Dec. 2, 1920, pp. 576-578. Two plants of 8000 hp. capacity each. Paper read before Eng. Inst. of Canada.

Norway. The Hydroelectric Plant at Vamma, Norway (L'usine hydroélectrique de Vamma (Norvège). Génie Civil, vol. 77, no. 21, Nov. 20, 1920, pp. 414-416, 3 figs. Total capacity will be 200,000 hp. Head varies from 25 to 27 m. and flow is about 220 cu. m. per sec.

Nova Scotia. Sheet Harbour Hydro-Electric Powers, Harold S. Johnston. Jl. Eng. Inst. Canada, vol. 3, no. 12, Dec. 1920, pp. 565-575, 4 figs. Schemes proposed with tables of run-off, etc.

Seattle, Wash. Seattle Building Large Municipal Hydro-Electric Development, C. F. Uhden. Eng. News-Rec., vol. 85, no 21, Nov. 18, 1920, pp. 994-996, 2 figs. Project for development of Upper Skagit River where ultimately about 500,000 hp. can be obtained.

South America. Survey of Power Plant Projects in South America. Power Plant Eng., vol. 24, no. 24, Dec. 15, 1920, pp. 1171-1173. Prepared by Guaranty Trust Co. of New York.

Surplus Water. Wasting Surplus Water at Hydroelectric Plants, L. W. Wyss. Power Plant-Eng., vol. 24, no. 23, Dec. 1, 1920, pp. 1126-1128, 3 figs. Description of various kinds of gates used to regulate overflow in hydroelectric stations.

Sweden. Utilizing Hydro-Electric Energy in Sweden. Elec. World, vol. 76, no. 24, Dec. 11, 1920, pp. 1167-1170, 2 figs. Experience with extensive high-tension system of Swedish Government. Method of grading station insulation and studies of lightning trouble. Plans for 200,000-volt transmission lines.

Switzerland. The Great Modern Hydroelectric Plants in Switzerland (Grandi impianti idroelectrici moderni in Isvizzera), Giovanni Rodio. Industria, vol. 34, no. 17, Sept. 15, 1920, pp. 425-431,

Utilization of Freshet Water. Utilizing Freshet Water for Power Generation, Clemens Herschel. Power, vol. 52, no. 22, Nov. 30, 1920, pp. 861-862, 1 fig. With properly designed venturi tube installed in discharge of hydraulic turbine power output can be increased maximum of 30 per cent by utilizing freshet water that would otherwise run to waste over dam.

HYDROPLANES

French. The French Hydroplanes at Antwerp (Les Hydroglisseurs Français a Anvers). Aéronautique, no 16, Sept. 30, 1920, pp. 152-154, 5 figs. Boats operated by aeroplane and propeller. Diagrams showing power required and resistance to traction.

I

ICE PLANTS

Electrically Driven. Electric Driven Raw Water Ice Plant, George B. Bright. Ice and Refrigeration, vol. 59, no. 6, Dec. 1920, pp. 246-248. Data and cost of operation.

Freezing Tanks. Ice Tank of New Design Gives Remarkable Results, C. Wilkie. Power, vol. 52, no. 21, Nov. 23, 1920, pp. 823-826, 8 figs. Ice tank is 114 ft. long, holding 856 cans, freezing 400-lb. blocks. Direct-expansion coils are in one end, flooded coils with horizontal accumulator in other end. 7 in. of agitation is produced by one propeller, 36 in. in diameter, at center of tank.

IGNITION

Battery Systems. A Compact Battery Ignition System. Automotive Industries, vol. 43, no. 24, Dec. 9, 1920, pp. 1162-1163, 4 figs. System designed by Vital Paquit, Belgian engineer Arrangement combines usual battery ignition units into small assembly resembling magneto in appearance and method of connection with engine.

INDUSTRIAL MANAGEMENT

Exposed Records. The Influence of Exposed Records on Output, F. M. Lawson. Eng. & Indus. Management, vol. 4, no. 20, Nov. 11, 1920, pp. 615-617. Permanent advantages are said to be (1) there is less stock carried, which means shorter investment period and consequent saving in money; (2) a smaller staff is required owing to ease with which information can be obtained; and (3) there is less switching men off from one job to another, owing to ease with which accurate decisions can be made.

Inspection. How the Inspection Department Helps the Factory, George S. Radford. Industrial Management, vol. 60, no. 6, Dec. 1920, pp. 418-421. Coordination of inspection with cost, assembling, routing and productivity.

Machine Shops. Finds Efficiency Lacking in Many Shops, H. M. Fitz. Iron Age, vol. 106, no. 25, Dec. 16, 1920, pp. 1609-1611. Inspection trip of 70 shops and factories revealed fact that large percentage has only partial or no system of management.

Opinion of Workers. What the Workers Think About Management—II, Albert Fry. Indus. Management, vol. 60, no. 6, Dec. 1920, pp. 437-440. Opinions from ironworkers, carpenters, inspectors, blacksmiths, machinists, patternmakers and others on individual responsibility, mental and physical tests and coöperation.

Organization Plan. Organization Plan that Typifies Modern Management, S. H. Bullard. Indus. Management, vol. 60, no. 6, Dec. 1920, pp. 441-444, 1 fig. Production system and organization plan of Bullard Machine Tool Co.

Production Method. Small-Quantity Production Methods, Earle Buckingham. Machy. (Lond.), vol. 17, no. 426, Nov. 25, 1920, pp. 213-215, 4 figs. Application of interchangeable manufacturing principles to methods employed when producing machines in limited quantities.

Routing Materials. Routing Considered as a Function of Up-to-Date Management—III, H. K. Hathaway. Indus. Management, vol. 60, no. 6, Dec. 1920, pp. 445-451, 12 figs. Method of routing assembled, multi-part mechanism.

Statistical Control. Making Statistics Talk—I, M. C. Rorty. Indus. Management, vol. 60, no. 6, Dec. 1920, pp. 394-398, 6 figs. Elements of statistical control. Application of statistical graphics to forecasting future trends.

Time Study. See TIME STUDY.

INDUSTRIAL RELATIONS

Business Organization of Labor. Labor as a Business, Not a Commodity—New Plan Proposed to Secure Industrial Peace, George H. Cushing. Manufacturers Rec., vol. 78, no. 21, Nov. 18, 1920, pp. 131-132. Suggests as basic solution for labor difficulty organization of labor on business basis. According to plan suggested capital would contract with labor for a certain amount of work to be done and would pay for it as a unit. Workmen would unite and sell their labor through representatives.

Closed Shop vs. Closed Shop Principles Paramount, James A. Emery. Iron Age, vol. 106, no. 25, Dec. 16, 1920, pp. 1606-1608. Attitude and policy of labor unions during war. (To be continued.) Address delivered before National Founders' Association.

The Closed Union Shop Versus the Open Shop: Their Social and Economic Value Compared, Ernest F. Lloyd. Nat. Indus. Conference Board, no. 11,

Industrial Democracy. What Makes a Labor Policy Successful? Norman G. Shidle. Automotive Industries, vol. 43, no. 20, Nov. 11, 1920, pp. 970-973, 1 fig. Industrial relations policy of Greenfield Tap & Die Corporation.

New Zealand. Conciliation and Arbitration in New Zealand. Nat. Indus. Conference Board, no. 23, Dec. 1919, 46 pp. Features of New Zealand legislation, and its operation in practice.

Open Shop. The Last Stand of the Open Shop, Roy W. Hinds. Coal Age, vol. 18, no. 21, Nov. 18, 1920, pp. 1037-1040, 2 figs. Developments of strike in coal fields of southern West Virginia and Kentucky.

The Open Shop Fight is a Fight for American Independence—The Closed Shop un-American and Destructive of all Individual Independence. Manufacturers Rec., vol. 78, no. 21, Nov. 18, 1920, pp. 106-108. Progress of movement for open shop throughout the United States.

Works Councils. A Works Council Manual. Nat. Indus. Conference Board, no. 26, Feb. 1920, 32 pp. 4 figs. Procedure for establishing works council.

Works Councils in the United States. Nat. Indus. Conference Board, no. 21, Oct. 1919, 135 pp. Results of studies of works councils in 225 American industrial establishments. Information, is brought down to August 1, 1919.

INDUSTRIAL TRUCKS

Transveyor. The Cowan Transveyor. Eng. and Indus. Management, vol. 4, no. 19, Nov. 4, 1920, pp. 598-600, 3 figs. Type of industrial truck for interdepartmental conveying, used in various British works.

INDUSTRY

Germany. Industrial Technique in Germany During the War (La technique et l'industrie de. l'Allemagne pendant la guerre), M. C. Lemaire. Annales des travaux publics de Belgique, vol. 21, no. 12, Oct. 1920, pp. 707-779. Developments of substitutes for raw material. Recuperation of industrial wastes. Experiments of riveting processes. Briquetting of coke. Production of lignite.

Problems of Labor and Industry in Germany. Nat. Indus. Conference Board, no. 15, Sept. 1920, 65 pp. Open shop principle has been recognized as basis for all relations between employer and employee, in spite of the fact that labor is almost completely organized and the Government has been encouraging organization among employers and employees.

INSULATORS, HEAT

Diatomaceous Earth. Diatomaceous Earth, Norris Goodwin. Chem. & Metallurgical Eng., vol. 23, no. 24, Dec. 15, 1920, pp. 1158-1160. Origin and uses. Bibliography of articles in technical magazines and list of patents bearing on use of diatomaceous earth as heat insulant and building material.

Hot-Air-Pipe Coverings. The Insulating Value of Various Coverings for Hot Air Pipes as Determined by Tests at the University of Illinois. Am. Architect, vol. 118, no. 2343, Nov. 17, 1920, pp. 648-652, 4 figs. It is concluded that use of thin sheets of asbestos paper on bright tin heat pipes result in waste of heat. Uncovered bright tin pipes were found to be more efficient carriers of heated air. Accumulation of dust and dirt on pipes does not greatly alter amount of loss. It is advised that unless insulation excels uncovered bright tin in heat insulation properties it should not be used.

INTERNAL-COMBUSTION ENGINES

Developments. Improvements in the Field of Internal-Combustion Engines (Neuerungen auf dem Gebiet der Verbrennungskraftmaschinen). Wirtschafts-Motor, no. 10, Oct. 1920, pp. 18-20, 8 figs. Details of recently patented engines and auxiliary devices.

Fuel Combustion. The Combustion of Fuels in the Internal-Combustion Engine, Thomas Midgley, Jr. Jl. Soc. Automotive Engr., vol. 7, no. 6, Dec. 1920, pp. 489-497 and (discussion) pp. 497-499, 18 figs. Recently developed optical gas-engine indicator. Indicator cards obtained with different fluids. Theory of knock and of knock suppressors.

Ignition. See IGNITION.

Lubrication. Castor Oil (L'huile de ricin), M. Martinot-Lagarde. Aéronautique, vol. 2, no. 17, Oct. 1920, pp. 187-190. Its value as lubricant for internal-combustion engines.

Water Injection. Water Injection in Gas and Oil Engines. Automobile Engr., vol. 10, no. 145, Dec. 1920, pp. 492-494. Consideration of application and effect.

[See also AEROPLANE ENGINES; AUTOMBILE ENGINES; DIESEL ENGINES; GAS ENGINES; GASOLINE ENGINES; HEAVY-OIL ENGINES.]

IRON

Electrodeposited. The Industrial Future of Electro-Deposited Iron, W. E. Hughes. Elecn., vol. 85, no. 2216, Nov. 1920, pp. 530-532, 4 figs. Developments in Europe.

Plates. Standard Specifications for Wrought-Iron Plates. U. S. Dept. Commerce, Bur. Foreign and Domestic Commerce, Industrial Standards, no. 27, 1918, 13 pp. Adopted by American Society for Testing Materials.

IRON ORE

World Supply. The Iron Ore Supplies of the World, F. H. Hatch. Geol. Mag., vol. 57, no. 677, Nov. 1920, pp. 504–517. Statistics by countries. From Lond. Times Trade Supp.

K

KINEMATICS

Acceleration Determinations. Acceleration Determinations—I, Henry N. Bonis. Am. Mach., vol. 53, no. 22, Nov. 25, 1920, pp. 977–981, 3 figs. General solution for Whitwork quick-return motion as generally applied to shaper mechanism.

Rolling Couples. Kinematic Study of Rolling Couples (Étude cinématique des couples de roulement), P. Massot. Technique Moderne, vol. 12, no. 4, April 1920, pp. 161–169, 20 figs. Application to design of machines of principles and formulas developed in previous installments. (Concluded.)

L

LABOR

Conservation of. Conservation of Labor, L. W. Wallace. Am. Mach., vol. 53, no. 24, Dec. 9, 1920, pp. 1104–1106. Address delivered at first meeting of American Engineering Council of Federated American Engineering Societies.

Hours of Work. Unwarranted Conclusions Regarding the Eight-Hour and Ten-Hour Workday. Nat. Indus. Conference Board, no. 14, Aug. 1920, 21 pp. Critical review of "Comparison of an Eight-Hour Plant and a Ten-Hour Plant," United States Public Health Bul. no. 106. It is claimed that conclusions presented therein are unscientific and unjustified by data offered, because the two plants from which data were obtained are not fairly comparable and basis of experience is too small to justify complete conclusions applicable to industry in general.

Strikes. See STRIKES.

Two-Shift vs. Three-Shift Day. The Development of the Technique of Changing from the Two-Shift to the Three-Shift Day in a Continuous Process, Robert B. Wolf. Jl. Engrs. Club of Phila., vol. 37–12, no. 192, Dec. 1920, pp. 463–469 and (discussion) pp. 469–478, 6 figs. Results obtained in three plants where change was made are illustrated and interpreted and suggestions are given in regard to change in management policy which should accompany change to three shifts.

LABOR TURNOVER

New York City. Labor Turnover in New York City. Am. Mach., vol. 53, no. 21, Nov. 18, 1920, pp. 933–935. Statistics

LABORATORIES

Aerodynamic. The New Testing Apparatus at the Airdynamic Institute at Saint-Cyr (Les Nouveaux Apparels D'Essais de l'Institut Aérotechnique de Saint-Cyr. Nature (Paris), no. 2426, Oct. 2, 1920, pp. 213–219, 10 figs. Airdynamic balance, wind tunnel and apparatus for testing propellers.

LAPPING

Modern Practice. Modern Lapping Practice. Machy. (Lond.), vol. 17 no. 423, Nov. 4, 1920, 129–137, 19 figs. Developments in lapping practice, including abrasives used in lap-charging methods, lapping thread gages, snap gages, measuring wires, flat surfaces, ring gages, die-casting dies and T-slots.

LATHES

Automatic. Recent Machine Tool Developments—XVII, Joseph Horner. Eng. vol. 110, no. 2864, Nov. 19, 1920, pp. 660–664, 10 figs. Types of automatic lathes.

Double-Carriage. Hamilton Double Carriage Production Lathe, J. V. Hunter. Am. Mach., vol. 53, no. 23, Dec. 2, 1920, pp. 1021–1022, 3 figs. Lathe equipped with two independent carriages, recently placed on market by Hamilton Machine Co., Hamilton O.

Turret. Efficient Automatic Machine Tool Records, F. Scriber. Can. Machy., vol. 24, no. 24, Dec. 9, 1920, pp. 513–514, 6 figs. Skeleton set-ups on turret chucking lathe are explained.

Using Turret Lathes in Railroad Shops, J. H. Moore. Can. Machy., vol. 24, no. 21, Nov. 18, 1920, pp. 447–451, 7 figs. Examples of their application to various kinds of work.

Universal Relieving Type. A New Universal Relieving Lathe. Machy. (Lond.), vol. 17, no. 426, Nov. 25, 1920, pp. 217–220, 5 figs. Final drive is by means of worm gearing. Built by Ward, Haggas & Smith, England.

LIGHTING

Factories. The Lighting of Shoe Factories, A. L. Powell and J. H. Kurlander. Trans. Illuminating Eng. Soc., vol. 15, on. 8, Nov. 20, 1920, pp. 603–630, 18 figs. Analyzes lighting requirements for individual machines and specifies what arrangement of illuminating apparatus best meets these needs.

Industrial. Some Out of the Ordinary Applications of Industrial Lighting, Samuel G. Hibben. Trans. Illuminating Eng. Soc., vol. 15, no. 8, Nov. 20, 1920, pp. 591–598 and (discussion) pp. 598–602, 17 figs. Recommendations in regard to method of mounting lamps.

New Incandescent Method. A New Incandescent Lighting Method (Ein neues Verfahren zur Glühlichtbeleuchtung). K. Bube. Zeit. für Beleuchtungswesen, vol. 26, nos. 15–16, Aug. 15–31, 1920, 116–117. Describes new patented method, in which a glower is brought into contact with solid fuel in the form of a paraffin core so that it absorbs the melting fuel and carries the flame. Points out advantages and economy of method.

LOCOMOTIVES

Articulated. Recent Types of Articulated Locomotives (Types récents de locomotives articulées), Lionel Wiener. Revue générale des Chemins de Fer, vol. 39, no. 3, Mar. 1920, pp. 155–210, 16 figs. European and American developments.

Australian. Standard Type Locomotives, New South Wales Government Railways Ry. Gaz., vol. 33, no. 20, Nov. 12, 1920, pp. 645–646, 2 figs. Express engine is of 4–6–0 type and freight engine of 2–8–0 type, both with outside cylinders.

Austrian. Four-Cylinder Compound Locomotive, with Six Coupled Driving Wheels and Superheaters, of the Württemberg State Railways (La locomotiva A 6 assi accoppiati (I–VI–O) A 4 cilindri compound, con surpriscaldamento del vapore, delle ferrovie dello stato del Württemberg. Industria, vol. 34, no. 19, Oct. 15, 1920, pp. 476–480, 6 figs.

Driving Box Shoes. Lining Driving Box Shoes and Wedges, J. McAllister. Ry. Mech. Engr., vol. 94, no. 12, Dec. 1920, pp. 788–791, 1 fig. Shoe and wedge layout. Pedestal jaw grinding machine.

Inspection. Report of the Bureau of Locomotive Inspection. Ry. Age, vol. 69, no. 25, Dec. 17, 1920, pp. 1071–1073, 1 fig. Outstanding feature of report of chief inspector of locomotives to Interstate Commerce Commission for fiscal year ending June 30, 1920, is increase in number of accidents and casualties resulting from failures of parts of locomotives and tenders. Application of water columns and other devices advocated.

Mikado. Mikado Type Locomotive for C.M. & St.P. Ry. Ry. Rev., vol. 67, no. 20, Nov. 13, 1920, pp. 729–731, 4 figs. Design is characterized by straightforwardness and follows closely details for light Mikado-type engines prepared by mechanical standards committee of United States Railroad Administration.

Mine. Flywheel Motor-Generator for the Drive of Mine Locomotives in Grängesberg (En svänghjulsomformare för gruvlokomotivdriften i Grängesberg), Gustaf Hjertén. Teknisk Tidskrift (Kemi & Bergsvetenskap), vol. 50, no. 9, Sept. 22, 1920, pp. 186–192, 14 figs. 225-hp. induction motor directly coupled with a d.c. dynamo, which is connected with the separately mounted flywheel having diameter of 2100 mm. and weighing 4800 kg. Formulas are presented for calculation of weight of wheel. Calculation of the losses in motor-generator and friction losses of flywheel.

Repairing. The Zwilling Staybolt (Der Stehbolzen "Zwilling"), H. de Neuf. Annalen für Gewerbe u. Bauwesen, vol. 87, no. 5, Sept. 1, 1920, pp. 35–38, 5 figs. Economic advantages of new type are said to be that it (1) reduces time required to repair locomotives, (2) increases life of locomotives, (3) diminishes work in shop, (4) affords possibility, with equipment and personnel of existing workshops, to reconstruct many more locomotives than heretofore, and (5) greatly reduces number of bolts required because of its durability.

Steam vs. Electric. Relative Advantages of Modern Steam and Electric Locomotives. Jl. Am. Inst. Elec. Engrs., vol. 39, no. 12, Dec. 1920, pp. 1044–1048. Comparison of two types, based on actual method of operation. Discussion at joint meeting of New York Sections of American Institute of Electric Engineers and Am.Soc.M.E.

Steam vs. Electric Locomotives, John E. Muhlfeld, F. H. Shepard, A. H. Armstrong. Mech. Eng., vol. 42, no. 12, Dec. 1920, pp. 680–687 and (discussion) pp. 687–688 and p. 726, 1 fig. Comparison in regard to initial and maintenance costs, reliability of service, efficiency of operation, and suitability of design. Data obtained in actual service of both types are presented and discussed.

Superheater. Steam Distribution with Superheated Steam. Ry. and Locomotive Eng., vol. 33, no. 12, Dec. 1920, pp. 368–370. Experiments made by French engineers in use of rotating valves. Translated from Génie Civil.

Technique. The Technique of Steam Locomotives (La technique des locomotives a vapeur), P. Drosne. Technique Moderne, vol. 12, no. 4, April 1920, pp. 145–150, 8 figs. Dynamic studies of steam locomotives. Graph comparing resistance curve obtained by calculation and by actual measurements of Pacific, Atlantic and 0–4–0 types.

LUBRICANTS

Requirements for. Anisotropic Fusion—Ideal Lubricants (Fusion anisotrope-lubréfiants idéaux), Marcel Brillouin. Journal de Physique, vol. 6, no. 2, Aug. 1920, pp. 33–38. Technical. It is held that unilateral or bilateral fluidity, rather than isotropic constitution, is ideal requirement for lubricant.

M

MACHINE TOOLS

Electric Equipment, Standardization of. Standardization of Electrical Equipment on Machine Tools. Iron Age, vol. 106, no. 21, Nov. 18, 1920, pp. 1322–1324 and pp. 1369–1371. Advantages of individual drive. Suggestions in regard to standardization.

Frame Design. The Stiffening of Machine-Tool Frames (Betrachtung über die Versteifung von Werkzeugmaschinenbetten), Ernst Peters. Betrieb, vol. 3, no. 2, Oct. 25, 1920, pp. 38–39, 3 figs. It is claimed that in machine-tool frames up to present time the twisting stress has not received sufficient consideration, and it is this that causes perceptible deformations and vibrations. Describes the zigzag rib constructed by author which, without increasing weight, is said to reduce the elastic deformation to fraction of its former value.

Glasgow Exhibition. The Glasgow Shipbuilding, Engineering, and Electrical Exhibition. Eng. Production, vol. 1, no. 13, Dec. 1920, pp. 475–476. Survey of most important tool and machine-tool exhibits.

Lead Screws. Precision Lead Screws. Machy. (Lond.), vol. 17, no. 423, Nov. 4, 1920, pp. 125–128, 5 figs. Grinding and inspection methods of Drummond Bros., Guildford, England.

Sawmill Machinery. Building Saw Mill Machinery, Fred H. Colvin. Am. Mach., vol. 53, no. 23, Dec. 2, 1920, pp. 1030–1032, 7 figs. Machine-tool equipment in typical plants in Pacific Coast States.

Small Machines. Small Machines for Building Optical Instruments, J. V. Hunter. Am. Mach., vol. 53, no. 23, Dec. 2, 1920, pp. 1045–1047, 6 figs. Miniature machines for use in manufacture of delicate instruments.

MACHINERY

Foundations. Foundations for Machinery, N. W. Akimoff. Mech. Eng., vol. 42, no. 12, Dec. 1920, pp. 671–672 and p. 699, 3 figs. Theory of causes leading to vibrations of machinery. Means for localizing expected vibration and of controlling resulting periods.

MALLEABLE IRON

American Industry. American Malleable Cast Iron—I, H. A. Schwartz. Iron Trade Rev., vol. 67, no. 23, Dec. 2, 1920, pp. 1536–1540, 4 figs. Series of related articles dealing with development of industry. Modern methods of manufacture, metallurgical principles involved and properties of American malleable iron.

Research. See RESEARCH, Malleable Iron.

MARINE BOILERS

Manufacture. Conference on the Unification of Rules for the Construction of Marine Boilers and Steam Pipes. Steamship, vol. 32, no. 378, Dec. 1920, pp. 153–155, 3 figs. Standard conditions for design and construction of marine boilers issued by British Board of Trade, 1920. (To be continued.)

MATERIALS

Substitutes for Various. German War Substitutes, A. Belter. Sci. Am Monthly, vol. 2, no. 4, Dec. 1920, pp. 333–336. Substitutes for metals, gasoline and benzine, lubricants and rubber. Translated from Industrie Chimique.

Testing. See NOTCHED-BAR TESTS.

MILLING

British Practice. Milling Operations on Herbert Lathes, I. W. Chubb. Am. Mach., vol. 53, no. 21, Nov. 18, 1920, pp. 945–950, 22 figs. Practice in British shops.

Thread. The Side Angle of Milled Threads (Ueber Flankenwinkel gefräster Gewinde), H. Friedrich. Werkstattstechnik, vol. 14, no. 17, Sept. 1, 1920, pp. 464–468, 16 figs. Experiments carried out in the machining of long screw spindles with square thread on the thread-milling machines of the Schuttoff & Bässler Corp'n, Chemnitz, show that with the calculated side angles correct a very accurate thread can be produced, but if side angle is in the slightest degree smaller than calculated, imperfections result.

MILLING CUTTERS

Helical. Making "Curvex" Milling Cutters. Machy. (Lond.), vol. 17, no. 425, Nov. 18, 1920, pp. 188–196, 17 figs. Methods and equipment employed by Pratt & Whitney Co. in manufacture of formed milling cutters with helical flutes.

MILLING MACHINES

Continuous. Continuous Miller Does Facing Work. Iron Trade Rev., vol. 67, no. 23, Dec. 2, 1920, pp. 1548–1549, 2 figs. Continuous type milling machine for facing to length crankshafts, camshafts and work of similar character. Built by Newton Machine Tool Works, Philadelphia.

Tables. Making Milling Machine Tables, Leroy M. Sherwin. Foundry, vol. 48, no. 23, Dec. 1, 1920, pp. 953–956, 7 figs. Molding and melting practices. Paper read before Am. Foundrymen's Assn.

MOLDING METHODS

Flasks for Locomotive Frames. How a Long Steel Flask is Assembled, Geo. W. Childs. Foundry, vol. 48, no. 22, Nov. 15, 1920, pp. 923–925, 5 figs. Method of assembling sections of flasks used in molding locomotive engine frames.

MOTOR PLOWS

British-Made. Improved Mechanical Ploughing Appliances. Engr., vol. 130, no. 3383, Oct. 29, 1920, pp. 428 and 434–435, 6 figs. Motor cable plowing outfit manufactured by John Fowler & Co., Leeds, England.

MOTOR-TRUCK TRAFFIC

Legislation. The Automobile Should Be Major Factor in Highway Traffic. Automotive Industries, vol. 43, no. 24, Dec. 9, 1920, pp. 1179–1180. Plea that legislation be directed toward making traffic safe for vehicles.

MOTOR TRUCKS

Body Standardization. Now is the Time for Standardization in Truck Body Measurements, J. Edward Schipper. Automotive Industries, vol. 43, no. 20,

ENGINEERING INDEX (Continued)

Nov. 11, 1920, pp. 962–963, 2 figs. Advantages of standardization. It is said that in addition to making lower price, it will be possible to make more competent and stable body building industry.

British Design. British Truck Show Reveals New Tendencies in Design, M. W. Bourdon. Automotive Industries, vol. 43, no. 24, Dec. 9, 1920. pp. 1154–1161, 16 figs. Decided changes in practice are noted since exhibition in 1913. Majority of trucks use overhead worm drive and pressed-steel frames are employed in three-fourths of models. T-head engine is being replaced by L-head type.

German. German Mechanical Transport Vehicles. Automobile Engr., vol. 10, no. 145, Dec. 1920, pp. 466–477, 35 figs. Notes on collection of captured vehicles at Aldershot, England.

Radiators and Cooling Fans on the German War Trucks, Karl F. Walker. Automotive Industries, vol. 43, no. 20, Nov. 11, 1920, pp. 960–961, 4 figs. Based on reports of examinations made by Motor Transport Corps of U. S. Army. Practically all radiators of German war trucks contained sheet steel shell with ribbon type of core.

Olympia Show. The Commercial Motor Exhibition. Automobile Engr., vol. 10, no. 144, Nov. 1920, pp. 440–444, 11 figs. Trend of design in heavy vehicles as shown in exhibition at Olympia Show.

Specifications. Internal-Combustion Truck Specifications. Power Wagon, vol. 25, no. 193, Dec. 1920, pp. 42–59. Principle characteristics of 504 makes.

Tipping Gears. Tipping Gears for Lorries—II. Colliery Guardian, vol. 120, vo. 3122, Oct. 29, 1920, pp. 1230–1232, 10 figs. British design.

MOTORCYCLES

German Designs. German Motorcycles and Auxiliary Motors for Cycles (Deutsche Fahrradhilfsmotoren und Motorfahrräder), H. Bernhard. Wirtschafts-Motor, no. 10, Oct. 1920, pp. 5–9, 11 figs. Details of various German construction types, including those with motors above and in front wheel, above and in back wheel, within cycle frame, with motor on an extra wheel, etc. Distinction is made between motor cycles and auxiliary motors attachable to any cycle.

Springing. The Springing of Motor Cycles, C. H. Savage. Automobile Engr., vol. 10, no. 144, Nov. 1920, pp. 457–462, 17 figs. Discussion of experiments made in France. From results obtained suggestions are made in regard to position of springs and their dimensions.

N

NICKEL-CHROMIUM ALLOYS

Types. Nickel-Chromium Alloys, Leon O. Hart. Min. and Metallurgy, no. 168, Dec. 1920, p. 39. Properties of various types used. (Abstract.)

NOTCHED-BAR TESTS

Impact Tests. Experimental Study of Impact Tests on Notched Bars (Étude experimentale sur les essais au choc des barreaux entaillés), André Cornu-Thenard. Revue de Métallurgie, vol. 17, no. 9, Sept. 1920, pp. 584–614, 40 figs. Influence of speed of impact on results of tests. (Continuation of serial.)

NOZZLES

Coefficient of Discharge. The Coefficient of Discharge of Elementary Nozzles, A. A. Jude. Jl. Instn. Mech. Engrs., no. 8, Dec. 1920, pp. 977–1017 and (discussion) pp. 1018–1037, 10 figs. Discusses potentialities of series apparatus and clears up unsatisfactory features relating particularly to variability of coefficient over supercritical range.

Theory of. The Theory of Steam-Turbine Nozzles (Zur Theorie der Düsen von Dampfturbinen), Aug. Wewerka. Zeit. für das gesamte Turbinenwesen, vol. 17, nos. 23, 24 and 25, Aug. 20, 30 and Sept. 10, 1920, pp. 265–268, 277–280 and 294–297, 15 figs. Deals with following problems: (1) Change in values of condition of flowing medium when flowing through nozzle; (2) weight or volume of steam flowing through a given nozzle; and (3) maximum final velocity under different steam conditions in front and back of nozzle. Gives most important equations for flow in nozzles, and it is shown how curves of normal and inclined nozzles with reduction of back-pressure can be derived, and graphic solutions for development of the curves are given.

O

OIL FUEL

Burner for. New System for Burning Fuel Oil, Charles W. Geiger. Power Plant Eng., vol 24, no. 24, Dec. 15, 1920, p. 1167, 1 fig. Burner in which air is introduced in burning oil.

Burning in Steam Cars. Liquid Fuel on Steam Waggons. Motor Traction, vol. 31, no. 819, Nov. 8, 1920, pp. 527–528, 3 figs. Application of Scarab liquid fuel system to Foden steam car.

Ships. Fuel Oil for Steamers, C. H. Peabody. Mar. Eng., vol. 25, no. 12, Dec. 1920, pp. 997–998. Grades of oil available for merchant vessels and their use.

Recent Advance in Oil Burning, Ernest H. Peabody. Twenty-eighth General Meeting, Soc. Naval Architects & Mar. Engrs., Nov. 11 and 12, 1920, no. 9, 11 pp., 8 figs. Progress in oil burning in ships of U. S. Navy. Graphs showing present efficiency obtained in boiler and furnace are included.

ORDNANCE

U. S. Navy Plant. Armor-Plate and Gun-Forging Plant of U. S. Navy, Roger M. Freeman. Mech. Eng., vol. 42, no. 12, Dec. 1920, pp. 657–668, and p. 726, 15 figs. Attention is called to arrangements of stockyard alongside open-hearth building, 30-ton electric furnaces for duplexing, electric traveling cranes to carry 400,000-lb. ingots, original "H" type of forge shop and treatment plant combined, 14,000-ton steam-intensified hydraulic press, twenty 15-ft. wide Carbottom furnaces, machine shop with three 106-ft. wide aisles and gun-treatment building, high portion of which contains 75-ton crane of 104-ft. span on rails 165 ft. above floor level.

OXY-ACETYLENE CUTTING

Cast Iron. Cast Iron Cutting with Oxweld Blowpipe. Acetylene Jl., vol. 22, no. 6, Dec. 1920, pp. 318–322, 8 figs. Procedure.

Cutting Cast Iron with the Oxy-Acetylene Torch, Alfred S. Kinsey. Welding Engr., vol. 5, no. 11, Nov. 1920, pp. 34 and 36–37, 4 figs. Following points are emphasized: Cast iron can be "cut" by combined melting-oxidizing action of oxy-acetylene torch; cutting of cast iron, even though rather roughly done, will be of fine advantage to shop practice in several ways; special cutting torch is unnecessary provided one is used which operates with excess acetylene, etc.

OXY-ACETYLENE WELDING

School for. Michigan State Auto School's Special Welding and Brazing Course. Acetylene Jl., vol 22, no. 6, Dec. 1920, pp 315–317, 4 figs. Methods of instruction at oxy-acetylene welding school.

OXYGEN CUTTING

Jet-Cutting Machine. The Godfrey Jet-Cutting Machine. Machy. (Lond.), vol. 17, no. 425, Nov. 18, 1920, pp. 185–187, 4 figs. Machine tool using jet of oxygen as cutting medium. Manufactured by Godfrey Engineering Works, England.

P

PAPER MANUFACTURE

Pope Patent. A Description of the Pope Patent. Paper, vol. 27, no. 10, Nov. 10, 1920, pp. 28–30, 8 figs. Invention relates to means for winding web of paper produced by paper-making machine onto winding-roll.

PARACHUTES

Postal. Postal Parachutes (Les parachutes posteax), L. P. Frantzen. Aerophile, vol. 28, nos. 17–18, Sept. 1–15, 1920, pp. 280–282, 10 figs. Models developed in England, France and United States.

Release. The Van Meter Parachute Release. Aviation, vol. 9, no. 11, Nov. 29, 1920, pp. 344–345, 2 figs. Release is automatic in action after release rod is pushed and in addition incorporates many safety features in its constructioo. It is applicable to all open cockpit machines. Jumper is lifted from seat and carried clear of machine.

PATTERNMAKING

Shops. Rehabilitate Shop in Record Time. Foundry, vol. 48, no. 22, Nov. 15, 1920, pp 897–901, 7 figs. Organization and equipment of patternmaking shop of Bryan Pattern & Machine Co., Bryan, Ohio.

PISTON RINGS

Design. Piston-Rings, L. G. Nilson. Jl. Soc. Automotive Engrs., vol. 7, no. 6, Dec. 1920, pp. 525–531 and (discussion) pp. 531–536, 22 figs. Survey of developments in design. Specifications for material for piston rings.

PLANERS

Sellers 16-ft. The Sellers 16-ft. Planer. Am. Mach., vol. 53, no. 22, Nov. 25, 1920, pp. 973–976, 3 figs. Planer weighs nearly one-half million pounds and was recently completed by William Sellers & Co., for large shipbuilding company.

POWER TRANSMISSION

Sonic Waves. Transmission of Energy by Vibrations of Liquids in Conduits (Sur la transmission de l'énergie par les vibrations de liquides dans les conduits), C. Camichel, D. Eydoux and A. Foch. Comptes rendus des Séances de l'Académie des Sciences, vol. 171, no. 17, Oct. 26, 1920, pp. 783–786. Technical study of power transmission by Constantinesco system of sonic waves.

PRESSES

Briquetting Cast-Iron Turnings. The "Boreas" Briquetting Press for Cast-Iron Turnings. Eng., vol. 110, no. 2863, Nov. 12, 1920, p. 638, 3 figs. Made in Copenhagen by Danish Machine Co. Finished briquets are in form of truncated cones and each weighs about $6^1/_2$ lb.

Safety Device. Making the Punch Press Safe and Efficient, Norman G. Shidle. Automotive Industries, vol. 43, no. 23, Dec. 2, 1920, pp. 1118–1120 and 1133. Examples of safety devices used.

Tools. Press Tools for Caterpillar Parts, Frank A. Stanley. Am. Mach., vol. 53, no. 22, Nov 25, 1920, pp. 987–988, 5 figs. Processes in manufacture of articles made from sheet metal or tubing.

PROFIT SHARING

Experience. Practical Experience with Profit Sharing in Industrial Establishments. Nat. Indus. Conference Board, no. 29, June 1920, 88 pp. Causes and circumstances which make some profit-sharing plans fail and others succeed.

Lyons Congress. Profit Sharing Recommended at Congress of Lyons (La participation aux bénéfices.—Le congrès de Lyon), F. Bayle. Revue générale de l'Électricité, vol. 8, no. 21, Nov. 20, 1920, pp. 735–739. Discussion of profit sharing as means for remedying industrial situation at Congress held at Lyon, October 1–2, 1920.

PULVERIZED COAL

Combustion. Pulverised Coal as Fuel. Lawford H. Fry. Eng., vol. 110, no. 2863, Nov. 12, 1920, pp. 628–631, 5 figs. Principles involved in combustion.

Grindle Burning System. For Burning Powdered Coal. Iron Age, vol. 106, no. 25, Dec. 16, 1920, pp. 1614–1615, 2 figs. Grindle equipment for burning powdered coal, manufactured by Combustion Economy Corporation, Chicago.

PUNCHING MACHINES

Tooling Arrangement. Two Light Punching-Machine Jobs, John Simon. Am. Mach., 53, no. 24, Dec. 9, 1920, pp. 1075–1077, 7 figs. Tooling practice in Austrian Machine Shop.

R

RADIOMETALLOGRAPHY

Methods. Examination of Materials by X-Rays (Emploi des rayons X pour l'examen des materiaux). Ouvrier Moderne, vol. 3, no. 8, Nov. 1920, pp. 309–314, 11 figs. Apparatus employed and results obtained.

RAILS

Electrical Properties. Behavior of Rails as Conductors of Electricity (Sul comportamento delle rotaie impiegate come conduttori di corrente elettrica), Lino Sandonnini. Rivista Tecnica delle Ferrovie Italiane, vol. 18, no. 3, Sept. 15, 1920, pp. 94–103, 13 figs. Laboratory determinations of resistence, coefficient of self-inductions, and other electrical properties of rails.

Failures. Decrease in Rail Failures Confirmed by Latest Statistics. Eng. News-Rec., vol. 85, no. 23, Dec. 2, 1920, p. 1071, 1 fig. Statistics of rail failures for principal carriers.

Wheel Pressures and Steel Rail Failures. Iron Age, vol. 106, no. 22, Nov. 25, 1920, pp. 1399–1400. Report of Committee on Safety of Railroad Operation to convention of National Association of Railway and Utilities Commissioners. Heat treatment suggested as remedy for failures.

Sink-Head vs. Ordinary Ingots. Steel Rails from Sink-Head and Ordinary Rail Ingots—III, George K. Burgess. Chem and Metallurgical Eng., vol. 23, no. 21, Nov. 24, 1920, pp. 1017–1022, 10 figs. Physical tests, metallographical examinations and chemical surveys. Comparison rails performed much better under drop test, and showed less abrasion under service tests.

RAILWAY ELECTRIFICATION

France. French Railways Electrifications—I. Elec. Ry. & Tramway Jl., vol. 43, no. 1055, Dec. 10, 1920, pp. 280–282. Translation of report issued by Ministry of Public Works. (To be continued.)

Holland. Electrification in the Netherlands (L'électrification des Pays-Bas), J.-C. Van Staveren. Vie Technique et Industrielle, vol. 1, no. 9, June 1920, pp. 204–206, 1 fig. Résumé of report of high tension committee appointed by association of directors of electric companies in the Netherlands.

Switzerland. Railway Electrification of the Erstfeld-Bellinzone Railway (Electrification de la ligne Erstfeld-Bellinzone). Bulletin Technique de la Suisse Romande, vol. 46, no. 21, Oct. 16, 1920, pp. 241–246, 5 figs. General description of works with notes on electric locomotives used.

The Electrification of the Gothard Railway. Ry. Gaz., vol. 33, no. 21, Nov. 19, 1920, pp. 668–670, 3 figs. Line is $139^1/_2$ miles long.

RAILWAY OPERATION

Emergency Car Service. Annual Report of Interstate Commerce Commission. Ry. Age, vol. 69, no. 24, Dec. 10, 1920, pp. 1019–1023. Review of year's activities under new law, including exercise of emergency car-service powers.

Payment of Wages. The Payment of Wages by Divisional Paymasters, T. W. Mathews. Ry. Age, vol. 69, no. 25, Dec. 17, 1920, pp. 1061–1064, 5 figs. Prompt and efficient payments effected on Seaboard Air Line by use of new check system.

RAILWAY REPAIR SHOPS

Chile. The New Railroad Shops at San Bernardo, Chile, Carlos Valenzuela Cruchaga. Am. Mach., vol. 53, no. 22, Nov. 25, 1920, pp. 982–986, 8 figs. Shops and equipment for repairing rolling stock of trunk line railway. Translated fron Ingenieria Internacional.

Great Northern Railway. Car Repair Shops for the Great Northern Ry., P. P. Barthelemy. Ry. Rev., vol. 67, no. 20, Nov. 13, 1920, pp. 725–726, 3 figs. Standard type of frame construction, car repair shed.

RAILWAY SIGNALING

Angereau System. Repetition of Signals on the Locomotive (Répétition des signaux sur les locomotives), F. Limon and C. Lebaupin. Annales des Mines, vol. 10, no. 9, 1920, pp. 245–256, 1 fig. Angereau radio-telegraphic system, employed by French railways, for repetition of signals on locomotive.

Automatic Block. Passenger Terminal Facilities at Richmond, Va., C. J. Kelloway. Ry. Signal Engr., vol. 13, no. 12, Dec. 1920, pp. 490–494, 4 figs. Interlocking and automatic block signaling system.

RILEY UNDERFEED STOKERS — MURPHY AUTOMATIC FURNACES

A Stoker to Meet Your Conditions

The type of Stoker you need is determined by the size of your boilers, fuel, load conditions and other local factors. Naturally, *one* type will not meet all these conditions but in the Riley Underfeed Stoker and Murphy Automatic Furnace you have a choice that will meet practically any condition.

For the plant with large boiler units *or with smaller units that are to be forced above rating* or where reserve capacity is essential, the Riley Underfeed Stoker meets the conditions. The moving grates —found only on the Riley—keep the fuel bed broken up and insure a mixture of air with coal that results in high capacity and efficiency.

For the plant with smaller boiler units or with *medium size boilers carrying a steady load*, the Murphy Automatic Furnace has proved its worth in thousands of installations. Operating on natural draft the original outlay is comparatively small. This furnace requires very little attention and the operator need not be so highly skilled.

The Murphy Furnace is the product of 44 years of investigation and development. With the use of poorer grades of coal in the last few years, improvements have been made to handle such fuel to the best advantage. Many of our clients report highly favorable operation with their old furnaces incorporating these improvements and used with the lower grade fuels.

Since no two plant conditions are alike, it will be to your advantage to utilize the experience of our engineers who will gladly analyze your power plant problem and recommend the equipment best suited to your needs.

Ask for our Stoker Catalog A-2 for Riley Stokers and AM-2 for Murphy Furnaces.

"A type to meet every stoker need"

ENGINEERING INDEX (Continued)

Three-Position Automatic System. The Signaling of the Ealing & Shepherd's Bush Railway. Ry. Gaz., vol. 33, no. 18, Oct. 29, 1920, pp. 571–577, 13 figs. Installation of three-position automatic signaling system, including special features with regard to control and working of signals and operation and detection of points.

RAILWAY TRACK

Construction. On the Question of the Construction of the Road Bed and of the Track (Subjected for Discussion at the Ninth Congress of the International Railway Association), Mr. Henry and Mr. Candelier. Bul. Int. Ry. Assn., vol. 2, no. 10, Oct. 1920, pp. 639–664, 20 figs. Based on replies to questionnaire sent out to railway companies in Belgium, Bulgaria, Spain, France, Protugal and Switzerland. Questions referred to deformation noticed in track, amount of traffic carried, measures adopted and results obtained.

Design. Railway Track Design. Ry. Gaz., vol. 33, no. 20, Nov. 12, 1920, pp. 637 and 644. Compares bull-head with flat-bottom track, and suggests that advantages of latter justify its adoption in England.

Standardizing Work. Methods of Standardizing Track Work, Earl Stimson. Ry. Rev., vol. 67, no. 22, Nov. 27, 1920, pp. 813–816. Experience of Baltimore & Ohio Railroad.

RAILWAYS

Equipment Performance. A Remedy for Our Transportation Ills, O. W. Stiles. Freight Handling & Terminal Eng., vol. 6, no. 8, Aug. 1920, pp. 291–294. Organization of equipment performance as means for increasing service.

Interstate Commerce Commission. Annual Report of Interstate Commerce Commission. Ry. Age, vol. 69, no. 25, Dec. 17, 1920, pp. 1075–1078. Review of year's activities under new law, with references to work of several bureaus.

REDUCTION GEARS

Design. Propelling Machinery for the New Cunarders. Shipbuilding & Shipping Rec., vol. 16, no. 22, Nov. 25, 1920, pp. 631–633, 4 figs. Double-reduction geared turbines for "Scythia," "Laconia" and other vessels.

REFRIGERATING PLANTS

Fish Storage. Plant for Refrigerating Fish at Lorient, France (Le frigorifique à poissons de Lorient, Morbihan), M. Verrière and M. Tayon. Génie Civil, vol. 77, no. 13, Sept. 25, 1920, pp. 245–250, 16 figs. partly on supp. plate. Data: Storage capacity, 2000 tons of fish; ice-making capacity, 120 tons of ice per day.

RESEARCH

Heating and Ventilating. Heating and Ventilating Research Work. Domestic Eng. (Lond.), vol. 40, no. 23, Nov. 1920, pp. 167–168. Investigations carried out for Manchester Corporation Air Pollution Advisory Board. (Abstract.)

Liquid Fuels. The Proposed Research Association for Liquid Fuels. Steamship, vol. 32, no. 377, Nov. 1920, pp. 122–126. Suggestions in regard to general scheme of research association. Address delivered before Diesel Engine Users' Association.

Malleable Iron. British Grey and Malleable Cast-Iron Research Association. Foundry Trade Jl., vol. 22, no. 227, Nov. 1920, pp. 839–846. Account of inaugural meeting held at Birmingham, England, on Sept. 30, 1920.

Steel Research Committee. Notes on the Report of the Steel Research Committee, J. H. S. Dickenson. Automobile Engr., vol. 10, no. 145, Dec. 1920, pp. 495–501, 7 figs. Committee was founded in 1916 jointly by Institution of Automobile Engineers and Society of Motor Manufacturers and Traders, to establish mechanical properties of ten standard automobile steels scheduled in B.E.S.A. Report No. 75.

RIVETED JOINTS

Stresses in. Determining True Net Sections of Riveted Tension Members by Diagrams. Can. Engr., vol. 39, no. 20, Nov. 11, 1920, pp. 512–513, 4 figs. Graphs give theoretically correct deductions of rivet holes for various gages and staggers.

RIVETING

Machines. English Type Electric Riveting Machine. Boiler Maker, vol. 20, no. 11, Nov. 1920, pp. 317–318, 5 figs. Manufactured by Mada Engineering Co.

Oiltight Work. Notes on Rivets and Spacing of Rivets for Oil-Tight Work, Hugo P. Frear. Twenty-eighth General Meeting, Soc. Naval Architects and Mar. Engrs., Nov. 11 and 12, 1920, no. 5, 10 pp. Rules and recommendations of American Bureau of Shipping, Bureau Veritas and Lloyd's Register.

Notes on Rivets and Spacing of Rivets for Oil-tight Work, Hugo P. Frear. Mar. Eng., vol. 25, no. 12, Dec. 1920, pp. 1008–1009. Information concerning oiltight practice of riveting for oiltight work. (Abstract.) Paper read before Soc. Naval Architects & Mar. Engrs.

ROLLING MILLS

Alloy-Steels. New Rolling Mill for Alloy Steels. Iron Age, vol. 106, no. 25, Dec. 16, 1920, pp. 1597–1599, 6 figs. Installation of Pennsylvania Forge Co., Bridesburg, Philadelphia. Five stands are served by tilting table on one side and traveling lifting table on other with runout over transfer table.

Brass. New Plant of the West Virginia Metal Products Corp. Metal Industry (N. Y.), vol. 18, no. 12, Dec. 1920, pp. 543–548, 4 figs. Plant has eight-hour minimum capacity of 80,000 lb. of finished brass and 20,000 lb. of finished copper.

Electrically Driven. Electric Rolling-Mill Equipment for Messrs. Steel, Peech & Tozer, Ltd. Elec. Rev. (Lond.), vol. 87, no. 2244, Nov. 26, 1920, pp. 675–677, 5 figs. Billet mill is of Morgan type and consists of four stands of 21-in. rolls and six stands of 18-in. rolls, and is driven by 1200 hp., 6300-volt, 3-phase, 50-cycle B.T.H. slip-ring type induction motor. (Concluded.)

Electric Rolling-Mill Equipment for Messrs. Steel, Peech & Tozer, Ltd. Elec. Rev. (Lond.), vol. 87, no. 2243, Nov. 19, 1920, pp. 643–646, 7 figs. Substation and cogging-mill equipment. (To be continued.)

Factors which Determine the Selection of Motors for Main Roll Drive, G. E. Stoltz. Proc. Engrs. Soc. Western Pa., vol. 36, no. 7, Oct. 1920, pp. 492–507 and (discussion) pp. 508–517, 17 figs. Examination of types used in various steel mills. Suggestions in regard to selecting type of motor for proposed installation.

Motor Equipment for Main Drive of Rolling Mills. Elecn., vol. 85, no. 2216, Nov. 5, 1920, pp. 541–547. List giving particulars of British electrically driven rolling mills.

Notes on Rolling Mill Drives, L. Rothera. Elecn., vol. 85, no. 2216, Nov. 5, 1920, pp. 514–517, 5 figs. Examples showing progressive increase in motor size.

Sheet and Tin Mills, A. B. Holcomb. Assn. Iron & Steel Elec. Engrs., vol. 2, no. 11, Nov. 1920, pp. 1–11 and (discussion) pp. 11–27. Advantages of electric drive for sheet and tin mills.

The Electric Drive of Rolling Mills, W. E. Taylor and C. E. Raeburn. Elecn., vol. 85, no. 2216, Nov. 5, 1920, pp. 524–528, 3 figs. Comparative economy of steam and electric drives. Based on records of operation of Canadian mill by steam drive and after its conversion to electric drive.

The Electric Reversing Mill Considered from the Standpoint of Tonnage, K. A. Pauly. Gen. Elec. Rev., vol. 23, no. 11, Nov. 1920, pp. 886–892, 6 figs. It is shown that increase in production can be secured by electric drive with less than same percentage increase in first cost of equipment. Paper read before Assn. Iron & Steel Elec. Engrs.

Variable Speed Rolling Mill Drives, W. E. Swale. Elecn., vol. 85, no. 2216, Nov. 5, 1920, pp. 522–523, 3 figs. Relative advantages of direct and alternating current.

Furnaces. Repairs Involve Unique Problems. Iron Trade Rev., vol. 67, no. 21, Nov. 18, 1920, pp. 1401–1403, 5 figs. Complete reconstruction of Columbus furnaces of American Rolling Mill Co. carried out in short time.

American Rolling Mill Furnaces Remodeled. Iron Age, vol. 106, no. 21, Nov. 18, 1920, pp. 1318–1319, 5 figs. Remodeling included increase in volumetric sizes and entire reconsideration of hot stoves.

S

SAFETY

Shop, Organization for. Safety Work Must be Well Planned, R. A. Salisbury. Foundry, vol. 48, no. 22, Nov. 15, 1920, pp. 895–896. Devise organized committees under direction of safety engineers and changing membership of committees frequently in order to educate workmen in safety.

Steel Works, Organization for. "Safety First" in a Steel works, H. S. Burn. Eng. and Indus. Management, vol. 4, no. 19, Nov. 4, 1920, pp. 589–590. Organization in large British Steel Works employing about 4000 workers.

SAND, MOLDING

Analysis. Judging Sands for Foundry Use—IV, Henry B. Hanlet and Herbert R. Simonds. Foundry, vol. 48, no. 22, Nov. 15, 1920, pp. 921–922. Methods of testing.

Testing. Investigates Steel Sand Properties, R. L. Lindstrom. Foundry, vol. 48, no. 23, Dec. 1, 1920, pp. 940–943, 18 figs. Methods of testing. Qualities required. Paper read before Am. Foundrymen's Assn.

SCIENTIFIC MANAGEMENT

See INDUSTRIAL MANAGEMENT.

SCREW THREADS

Specifications. Report on Coarse and Fine Threads. Can. Machy., vol. 24, no. 17, Oct. 21, 1920, pp. 374–377. Tables of tolerances, and specifications.

Standards. Report of the German Industry Committee on Standards (Mitteilungen des Normenausschusses der Deutschen Industrie). Betrieb, vol. 3, no. 2, Oct. 25, 1920, pp 17–21, 5 figs. Proposal of Board of Directors for flange joints, round threads and flat hexagonal threads. Proposed standards for sink-water traps with opening for cleaning.

SCREWS

Standards. Report of the German Industry Committee on Standards (Mitteilungen des Normenausschusses der Deutschen Industrie), Betrieb, vol. 3, no. 1, Oct. 10, 1920, pp. 1–14, 17 figs. Proposals of the Board of Directors for special standard dimensional values and for driver's seat in agricultural machines. Proposed standards for square and hexagon head Whitworth cap screws, bolts and nuts, lag screws; sink-water traps, etc. Rules of the Committee for standards and formula values.

SHAFTS

Critical Speeds. Calculation of the Critical Speeds of Shafts (Die Berechnung kritischer Drehzahlen von Biegungswellen), H. Lorenz. Zeit. für das gesamte Turbinenwesen, vol. 17, nos. 20 and 21, July 20 and 30, 1920, pp. 229–232 and 245–249, 5 figs. Gives method for calculating critical speed of a shaft under a given load and arrangement of bearings which, however, can be applied only in simple cases. The employment of the Kull approximative formula is recommended for calculation of complicated cases.

Critical Speed and Gyroscopic Action (Kritische Drehzahl und Kreiselwirkung), R. Grammel. Zeit. des Vereines deutscher Ingenieure, vol. 64, no. 44, Oct. 30, 1920, pp. 911–914, 2 figs. Based on newly derived differential equation of a uniformly revolving vertical shaft, it is shown that, as a result of the gyroscopic action of the disks, there are no longer such unlimited number of critical revolutions; their number is determined according to the surface conditions; and it is explained how they can be altogether prevented. It is also explained how critical speeds vary when length of shaft or diameter of disk is changed. The critical speeds of the second class are investigated in same manner.

SHIPBUILDING

Great Britain. The Relation Between Shipbuilding Production, Prices, and the Freight Market, Maxwell Ballard. Trans. Northeast Coast Instn. Engrs. & Shipbuilders, Advance paper no. 3224–O, 17 pp., 8 figs. Economic position of shipping and shipbuilding industries of Great Britain.

Production Systems. Production Methods in Shipbuilding—V, William B. Ferguson. Indus. Management, vol. 60, no. 6, Dec. 1920, pp. 409–412, 2 figs. Discusses piece work in its application to shipbuilding and shows how varied nature of work involving many trades makes it necessary to depart from any one hard and fast system of bonus payment. Application of Halsey premium systems and 100-per cent time-premium plan and results obtained therefrom in increasing output of yard are set forth.

SNOW PLOWS

Rotary. The Development of Snow Fighting Equipment, W. H. Winterrowd. Ry. Maintenance Engr., vol. 16, no. 12, Dec. 1920, pp. 458–462, 8 figs. Rotary plows of Canadian Pacific Railways.

SOLAR ENERGY

Utilization of. Utilization of Solar Energy (Le soleil générateur de force motrice), Emmanuel Zoude. Revue Universelle des Mines, vol. 7, no. 4, Nov. 15, 1920, pp. 255–278, 12 figs. Method for generation of steam by solar rays invented by Frank Shuman of Philadelphia, and its application in installation at Meadi, Egypt, by British Corporation, owner of Shuman patents.

STEAM

Formulas. Steam Formulas, Robert C. H. Heck. Mech. Eng., vol. 42, no. 12, Dec. 1920, pp. 669–670, 4 figs. Critical comparison of various existing formulations and development of new set of general equations. Formulas are developed for temperature, pressure and heat content.

Generation by Solar Rays. See SOLAR ENERGY.

Superheated, in Textile Mills. Superheated Steam in Textile Power Plants, Pell W. Foster, Jr. Textile World Jl., vol. 58, no. 23, Dec. 4, 1920, pp. 113–117, 4 figs. Its adaptability to the problems of textile-mill engineer.

STEAM-ELECTRIC PLANTS

Oshkosh, Wis. Electric Power at Oshkosh, Wis., T. J. Lucas. Power Plant Eng., vol. 24, no. 24, Dec. 15, 1920, pp. 1155–1161 and pp. 1186–1189, 15 figs. Replacement of reciprocating units by two vertical Curtis 500-kw. turbine units and later supplemented by 500-kw. horizontal Allis-Chalmers Parsons unit.

Unit Systems. Electrical Features of Springdale Plant, George S. Humphrey. Elec World, vol. 76, no. 23, Dec. 4, 1920, pp. 1114–1118, 8 figs. Details of 30,000-kw. unit of West Penn Power Co. Plant is arranged on unit system, main generator having its own boilers, auxiliaries, transformers and bus sections.

STEAM ENGINES

Piston Displacement. Piston Displacement, Velocity and Acceleration for Reciprocating Engines, John L. Bogert. Mar. Eng., vol. 25, no. 12, Dec. 1920, pp. 983–989, 10 figs. Table and graphs giving piston displacement, velocity and acceleration for various rations of connecting rod to crank.

Uniflow. Further Tests of the Uniflow Pumping Engine, D. A. Decrow. Jl. New England Water Works Assn., vol. 34, no. 3, Sept. 1920, pp. 195–199. Results of tests indicate that permissible speeds of this type of pumping engine are much higher than considered advisable for familiar types of crank and flywheel pumping engines; results as to speed economy indicate higher economy for higher speeds and temperatures.

STEAM POWER PLANTS

Test Codes. Power Test Codes. Mech. Eng., vol. 42, no. 12, Dec. 1920, pp. 718–719 and p. 725. Preliminary draft of first of 19 codes which the American Society of Mechanical Engineers Committee on Power Test Codes is formulating.

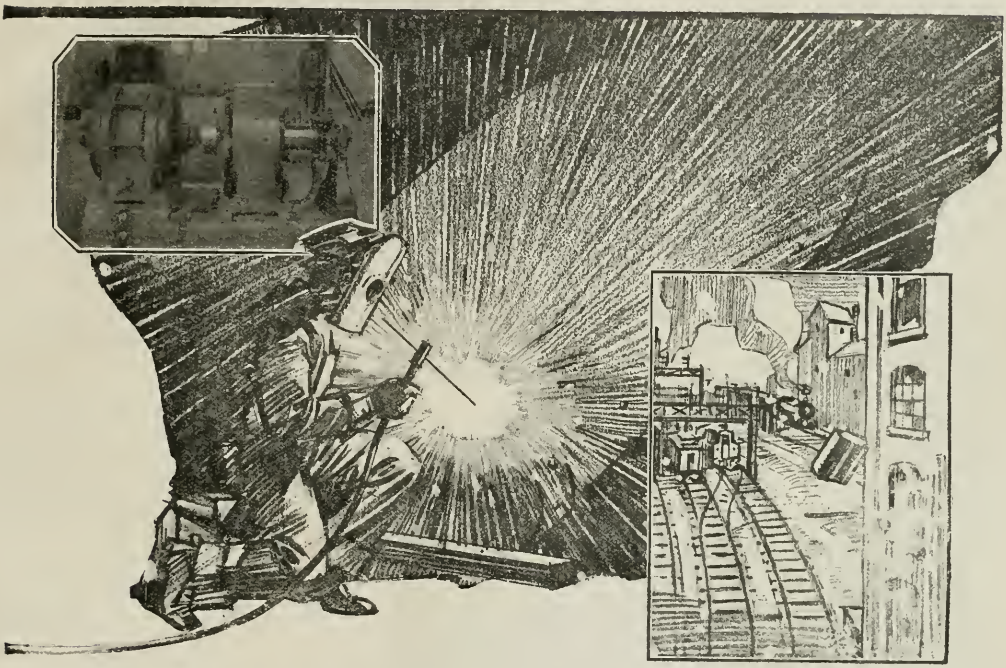
STEAM TURBINES

Operation and Adjustment. Operation and Adjustment of Turbine Machinery—XII—Oil Pumps, Eustis H. Thompson. Power, vol. 52, no. 22, Nov. 30, 1920, pp. 863–864, 3 figs.

STEEL

Aircraft. Some Notes on Aircraft Steels and Their Inspection, R. K. Bagnall-Wild. Flight, vol. 12,

Sometimes the producer is so absorbed with the task of producing, that he overlooks means which might make his plant more productive



A Welded Seam with All the Strength of the Original Metal

Full of oil and sealed tight a tank was dropped from a four-story building onto a railroad track, and nothing but a dent in the tank! A real test of strength, and yet the electric arc welded seam did not leak or show a sign of weakness. Electric welding makes every seam a part of the product itself, rather than a connection which merely holds it together.

In every industry wherever metals are joined together, the electric weld is stronger, more durable, and permits special construction and more efficient design of parts than is possible with bolts and rivets. Its uses are so varied that in places where it is installed for a certain purpose, it soon develops a greater usefulness as men become more familiar with its operation.

To make electric arc welding a real factor in production, the General Electric Company has developed arc welding equipment for almost every purpose, large and small, suitable for factories where there is enough welding to keep one or many men busy.

Whether your welding problems require a small portable set or a large stationary outfit, the knowledge and experience of G-E specialists and their co-operation are available for the asking.

Select the right equipment for the work—and a welder who knows his business

ENGINEERING INDEX (Continued)

T

TEMPERING

Reheating. Tempering and Reheating of Metallurgical Products (La Trempe et le revenu des produits métallurgiques), Léon Guillet. Revue générale des Sciences, vol. 31, nos. 17–18 and 19, Sept. 15–30 and Oct. 15, 1920, pp. 564–581, 34 figs, and 614–620, 5 figs. Influence of different methods of reheating on resulting hardness of alloy steels and bronzes. Diagrams and photomicrographs. Theory of tempering.

TERMINALS, MARINE

Mechanical Handling Equipment. Mechanical Handling Equipment as a Means of Reducing Expensive Terminal Costs, G. F. Nicholson. Freight Handling and Terminal Eng., vol. 6, no. 10, Oct. 1920, pp. 377–384. Type of equipment required. Paper read before Pacific Coast Port Authorities Annual Convention.

TIDAL POWER

Severn Barrage Scheme. The Severn Barrage Scheme. Elecn., vol. 85, no. 2220, Dec. 3, 1920, pp. 659–660, 1 fig. Scheme for utilizing over one-half million horsepower of tidal energy. Designs have been worked out by civil engineering department British Ministry of Transport.

Utilization of. Utilization of the Tides (Utilisation des marées), Amiral Amet. Revue générale de l'Électricité, vol. 8, nos. 16 and 17, Oct. 16 and 23, 1920, pp. 531–542, 11 figs., and 565–575, 9 figs. Scheme for utilizing tidal power at Saint-Malo, France.

TIME STUDY

Small-Part Manufacture. Time Study in Small Part Manufacture, Philip Bernstein. Indus. Management, vol. 60, no. 6, Dec. 1920, pp. 401–406. Practical procedure on drilling, profiling, hand and power milling, automatic screw machine and other operations.

TOOLS

Grinding. Grinding Expedites Tool Building, Douglas T. Hamilton. Iron Trade Rev., vol. 67, no. 22, Nov. 25, 1920, pp. 1472–1475, 11 figs. Practice at plant of Fellows Gear Shaper Co., Springfield, Vt.

TRADE UNIONS

Legal Responsibility. Should Trade Unions and Employers' Associations be Made Legally Responsible? Forest R. Black. Nat. Indus. Conference Board, no. 10, June 1920, 35 pp. It is shown that rules of legal liability in theory apply to unincorporated associations in much the same way as to partnerships or corporations, but that as practical matter it is more difficult for plaintiff to conduct litigation and it is particularly difficult to reach funds. This state of affairs is undesirable and special legislation to legalize trade unions is suggested, as it is held that ordinary law of corporations cannot well apply to them.

TRANSPORTATION

Progress in. Education and Training in Transport. Tramway & Ry. World, vol. 48, no. 25, Nov. 18, 1920, pp. 277–280. Progress in transportation and modern civilization. Presidential address before Inst. of Transport.

Rail and Water. The Coördination of Rail and Water Transport, Charles H. Markham. Ry. Age, vol. 69, no. 25, Dec. 17, 1920, pp. 1057–1060. Railways and waterways not naturally competitors and should work together. Railway ownership of boat lines. Paper read before River and Harbor Congress.

V

VANADIUM STEEL

Analysis. Analysis of Vanadium in Steels (Dosage du vanadium dans les aciers), Emile Jaboulay. Revue de Métallurgie, vol. 17, no 9, Sept. 1920, pp. 627–629. Method consists in dissolving metal in sulphuric acid and transforming vanadium into vanadic acid by action of potassium permanganate.

VIBRATIONS

Machinery. Vibration, Julius Frith. Eng., vol. 110, no. 2863, Nov. 12, 1920, pp. 657–658, 1 fig. Analytical study of vibration, specially that of crankshafts, flywheels and alternating-current generators.

W

WAGES

Minimum. Legal Minimum Wages, Douglas Knoop. Discovery, no. 12, Dec. 1920, pp. 364–368. Advocates fixing legal minimum wages in each trade by establishing Trade Board for that trade, consisting of members representing employers and employees in equal numbers and of three independent persons, preferably professional men and women.

Rates. Should the State Interfere in the Determination of Wage Rates? Harleight H. Hartman. Nat. Indus. Conference Board, no. 12, Aug. 1920, 158 pp. State interference is said to be expedient because it prevents actual pecuniary loss to employer, employee and public, and because it places industrial disputes upon a basis of substantial justice rather than force.

Reduction. What Are You Doing About Wages? Neil M. Clark. Factory, vol. 25, no. 12, Dec. 15, 1920, pp. 1869–1874. Opinions of manufacturers and leaders of labor unions in regard to advisability of reducing present standard of wages.

What Will Employers Do About Wages? Don F. Kennedy. Iron Age, vol. 106, no. 24, Dec. 9, 1920, pp. 1543–1544. Plea for frankness in dealing with employees.

Wage-Incentive Systems. The Bases of Emerson Incentive, Harrington Emerson. Indus. Management. vol. 60, no. 6, Dec. 1920, pp. 413–416. Comparison of wage-incentive systems.

Common Labor Responds to Incentives, J. D. Town. Indus. Management, vol. 60, no. 6, Dec. 1920, pp. 422–424. Satisfactory results of introducing bonus system in foundry.

WATER POWER

Development in U. S. Development of National Water-Power Resources, C. D. Wagoner. Eng. World, vol. 17, no. 6, Dec. 1920, pp. 439–441, 3 figs. Statistics of developed and undeveloped water-power in United States.

France. Harnessing the Rhône River by Deviating Its Course (Nouveau project d'aménagement du Haut-Rhône par dérivation), Genie Civil, Sept. 25, 1920, pp. 250–255, 3 figs. To better utilize hydraulic energy of Rhône where river course follows nearly circular path, it is proposed to construct tunnel between extremities of arc. Economies of such project and of another involving construction of dams at points in circular course of river are compared.

The Harnessing of the Rhône (L'aménagement du Rhône), J. Tribot-Laspière. Technique Moderne, vol. 12, no. 4, April 1920, pp. 151–154, 1 fig. Details of project adopted by French Chamber of Deputies, and its economical advantages.

Hydrographic Study and Harnessing of the Toce-Devero Basin (Étude hydrographique et aménagement du bassin Toce-Devero), G. Malgorn. Electricien, vol. 36, no. 1263, Nov. 1, 1920, pp. 457–461, 6 figs. Economic advantages of utilization of water power of region. (Concluded.)

Germany. Hydro-Electric Power in Germany. E. Sympher. Elecn., vol. 85, no. 2218, Nov. 19, 1920. p. 590. Deals with nationalization of electrical industry, which was legally enacted Dec. 31, 1919 and describes new schemes, including the Rhine-Danube canal and the Moselle-Saar canals. Abstract from Elektrotechnische Zeit. of paper read before Instn. German Elec. Engrs.

The Unlimited Utilization of German Water Power a Present-Day Necessity (Die restlose Erfassung unserer Wasserkräfte, ein Gebot der Gegenwart), W. Halbfass. Elektrotechnische Zeit., vol. 41, no. 40, Oct. 7, 1920, pp. 792–794. Points out that the water power of German rivers can be better and more completely utilized when their development is effected not simply by means of ordinary gradient-section works, but in connection with dams. Writer recommends, besides the construction of large water-power plants, that of small plants which require much less expenditure and serve many useful purposes, a special field for their use being the utilization of so-called water-power wastes.

Great Britain. Water-Power Resources and Projects in United Kingdom, Robert P. Skinner. Commerce Reports, no. 287, Dec. 7, 1920, pp. 1051–1053. Water-power resources committee of British Board of Trade recommends that controlling water commission be established by act of Parliament.

Niagara Falls. Niagara's Mighty Power will Breed Lively Fight. Water Power, vol. 1, no. 5, Nov. 1920, pp. 10–12, 2 figs. Rival applicants for right to use flow of cataract after filing applications with Federal Power Commission. Schemes contemplated are discussed.

St. John River, Canada. Storage and Power Possibilities on St. John River, A. Langlois. Contract. Rec., vol. 34, no. 49, Dec. 8, 1920, pp. 1169–1170, 1 fig. Regulation of flow at reversible falls to improve navigation and permit development of power.

WAVES

Elastic Solids, Speed in. Speed of Waves in Elastic Solids (Sur la célérité des ondes dans les solides élastiques), E. Jouguet. Comptes rendus des séances de l'Académie des Sciences, vol. 171, no. 11, Sept. 13, 1920, pp. 512–515. Formulas.

WELDING

Electric. See ELECTRIC WELDING.

Oxy-Acetylene. See OXY-AXCETYLENE WELDING.

WELDS

Testing. Study of the Testing of Welds, S. W. Miller. Blast Furnace & Steel Plant, vol. 8, no. 12, Dec. 1920, pp. 678–683, 26 figs. Bend test. Microscopic and macroscopic study of welds. Paper read before Am. Welding Soc.

The Testing of Welds in Steel Plants, S. W. Miller. Ry. Mech. Engr., vol. 94, no. 12, Dec. 1920, pp. 792–794, 9 figs. Conditions which affect quality of welds; simple bend test and etching of sections recommended. Paper before Am. Welding Soc.

WELFARE WORK

Industrial Hygiene. Economic Aspect of Industrial Hygiene, Bernard J. Newman. Indus. Management, vol. 60, no. 4, Oct. 1920, pp. 271–273. Relation between health and general welfare of employees and their working efficiency.

Restaurants. A Centralized Organization for Feeding Men, Hunter McDonald. Ry. Maintenance Engr., vol. 16, no. 12, Dec. 1920, pp. 469–472, 11 figs. Plan in use by Nashville, Chattanooga & St. Louis Railway. Paper read before Am. Ry. Bridge & Building Assn.

Solves Problem of Feeding Army of Workers. Iron Age, vol. 106, no. 24, Dec. 1920, pp. 1527–1530, 9 figs. Dining room at East Pittsburgh works of Westinghouse Electric & Mfg. Co., where 50,000 persons are employed.

Savings Association. Our Savings Association as an Aid to Management, C. L. Walker. Factory, vol. 25, no. 11, Dec. 1, 1920, pp. 1715–1718, 5 figs. Experience of A. W. Shaw Co.

Savings Plan. How One Community Has Succeeded in Getting Employees to Save, John F. Tinsley. Factory, vol. 25, no. 12, Dec. 15, 1920, pp. 1899–1901, 4 figs. Plan employed at Worcester Works in Massachusetts.

Sick Leave With Pay. A Plan for Sick Leave With Pay, Morris R. Machol. Indus. Management, vol. 60, no. 6, Dec. 1920, pp. 453–454. Method is based on length of time employee has been in service of company.

Welfare Department. Is "Welfare Work" Accomplishing Constructive Results? Norman G. Shidle. Automotive Industries, vol. 43, no. 13, Sept. 23, 1920, pp. 619–621. Suggests auditing "welfare" department and making it justify its existence just as definitely as in production department.

WHEELS

Cast-Iron, Grinding. Grinding Cast Iron Wheels. Ry. and Locomotive Eng., vol. 33, no. 12, Dec. 1920, pp. 345–349, 2 figs. Machine for grinding wheels. Tables showing data of measurements of slid flat wheels.

WIND MOTORS

Efficiency of. Wind-Driven Airscrews (Ueber vom Windegetriebene Luftschrauben), M. Munk. Zeitschrift für Flugtechnik u. Motorluftschiffahrt, vol. 11, no. 15, Aug. 15, 1920, pp. 220–232, 1 fig. Determination of the efficiency of the wind wheel, and discussion of the aspects governing proportion of vanes.

Theory of. Theory of the Ideal Wind-Power Machine (Theorie der idealen Windkraftmaschine), Wilhelm Hoff. Zeitschrift fur Flugtechnik u. Motorluftschiffahrt, vol. 11, no. 15, Aug. 15, 1920, pp. 223–227, 8 figs. Develops relation between air propellers and windmills and shows that the theory of the ideal jet motion is applicable to the ideal wind power machine. Supplement to article by M. Munk in same issue of journal.

WIND POWER

Utilization of. The Maximum Theoretically Possible Utilization of Wind through Wind Motors (Das Maximum der theoretisch möglichen Ausnützung des Windes durch Windmotoren), A. Betz. Zeit. für das gesamte Turbinenwesen, vol. 17, no. 26, Sept. 20, 1920, pp. 307–309. Equations are derived for calculation of the maximum amount of energy which can be produced with a windmill of a given diameter operating without loss.

The Study and Design of Wind-Power Plant (Beitrag zur Kenntnis und zum Entwerfen von Windkraftanlagen), M. Mayersohn. Zeit. des Vereines deutscher Ingenieure, vol. 64, no. 45, Nov. 6, 1920, pp. 925–931, 14 figs. Abstract of treatise approved by machine-construction department of Berlin Technical Academy on wind-power plants and their usefulness in Palestine, discussing practical types of wind motors and recording operating experiences with different plants. Suggestions for planning wind-power plants are made.

The Utilization of Wind Power for the Generation of Electricity (Udnyttelse af Vindkraften til Fremstilling af Slektricitet), E. Adler. Ingenioren, vol. 29, no. 78, Sept. 29, 1920, pp. 595–598, 3 figs. Points out that Denmark is far in advance of other countries in utilization of wind power, partly because of its climate and partly because of work of Professor La Cour. One difficulty is said to be that generators of windmills, because of the storage, must deliver direct current, whereas country's system is equipped for alternating current, as remedy for which, writer recommends the coupling of wind mill with an induction generator.

Wind Turbines (Les turbines a vent), E. Weiss. Nature (Paris) no. 2429, Oct. 23, 1920, pp. 257–259, 7 figs. Escaffre wind turbine at Paris fair.

WIND TUNNELS

German. Report on German Wind Tunnels and Apparatus, Edward P. Warner. Aerial Age, vol. 12, no. 11, Nov. 22, 1920, p. 298. Zeppelin wind tunnel at Friedrichshafen. (Concluded.)

WIRE MANUFACTURE

Processes. Modern Process of Drawing Wire, L. Dwight Granger. Blast Furnace & Steel Plant, vol. 8, no. 12, Dec. 1920, pp. 661–663. Practical application surrounded by great many technical considerations with reference to speed of wire through dies. Annealing and composition of material.

WOMEN WORKERS

Advisability. The New Place of Women in Industry—III, Ida M. Tarbell. Indus. Managment, vol. 60, no. 6, Dec. 1920, pp. 399–400. Management of women workers.

WOOD

Treatment of. Treatment, Seasoning and Fireproofing of Industrial Wood (Imprégnation, sénilisation et ignifugation des bois d'industrie), J. Escard. Houille Blanche, vol. 19, no. 43–44, July-Aug. 1920, pp. 148–151. Chemical compounds used for treating. (Continuation of serial.)

Volume 43 March, 1921 Number 3

Industry's Supply of Energy

A Survey of the Available Supplies of Coal, Oil, and Water, Together with a Discussion of the Engineer's Part in the Economic and Efficient Utilization of Energy Units

By GEORGE OTIS SMITH,[1] WASHINGTON, D. C.

EDWARD EVERETT HALE charted the course of industrial development when he said that the extent to which the world had changed the laborer who uses his body into the workman who uses his head was the index of civilization. That distinction between laborer and workman is the contrast between the old and the new order. The formula for modern industry is man plus mechanical energy, or, better expressed, it is man multiplied by his machines. The true measure of industrial progress is found in the amount of mechanical power used to supplement man power. As mechanical engineers you may have been so devoted to the task of perfecting the application of power to man's use that you have had little time to think of the sources of the energy you use or to estimate the supply of energy available. The present scope and future possibilities of your profession take on larger dimensions if we survey the whole field and so appreciate better its vast extent. As I see the task of the mechanical engineer, he is the guide who best knows the routes by which mankind must travel in order to take full possession of the stores of energy that await utilization.

For contrast with the present era of machine-aided civilization we naturally turn to the days of ancient Rome or Greece or Egypt, when hordes of slaves toiled both in the erection of those great monuments that have been called the "wonders of the world" and in the performance of the daily tasks of providing the necessities and luxuries of that age. Man power then made use of only the simplest laws of mechanics. Far less depressing is it to go still further afield and recall those tales of the Arabian Nights wherein the slaves of the lamp performed their work with the ease and dispatch that accords more nearly with the methods of today. To what extent is it granted to us of this day and generation to rub the modern Aladdin's lamp and summon the genii to do our bidding? How many servants have we working for us?

I find that several writers on the subject of power have estimated the number of energy servants in our employ, and these estimates are based upon the installed capacity of our prime movers, which is approximately 100 million horsepower, or nearly one horsepower to each man, woman, and child in the United States. Using the equivalent of ten man-power hours to the horsepower-hour we find in this the suggestion that we each have the equivalent of ten servants to do our bidding. But even mechanical power has some of the frailties of human power: capacity and performance are rarely equal. So, if we take the statistics of the energy output that we really utilize we discover that these energy servants work very short days, for, with the exception of the electric utilities, our prime movers do not give us anything like the equivalent of an 8-hour day in terms of their rated capacity. The steam locomotives, which represent perhaps 60 per cent of the total installed capacity, average only about a 7 per cent use factor, which brings down the average load factor to not much over 14 per cent.

These workers, represented by the water turbine and the steam engine, are tireless, it is true, and they are able to render continuous service as man power cannot, yet the fact is that we do not so use them. We may figure that we each have ten energy servants to help us in the world's work, but as they average only about 23½ hours a week a better statement would be that we each of us have the equivalent of five slaves working for us day by day. You will note that this estimate is arrived at by figuring that with a 14 per cent load factor it takes nearly two installed horsepower to equal one continuous horsepower for the human week of 44 hours. This quota of five energy servants for each of us is far in excess of what the Greeks possessed in the form of human slaves, five helots being, I understand, the power equipment of the average Greek freedman's family, or nearer one apiece, when Greek culture rested on a substratum of slave labor.

The census of our energy slaves I have just taken does not include the millions of automotive engines in our pleasure cars, trucks and tractors, which may in rated capacity far exceed that of the prime movers I have mentioned. Yet it might be difficult to figure the load factor of these engines and so to calculate in horsepower the service they render to us. Horsepower is indeed the appropriate measure of the work these automotive engines perform, as they are substitutes for the horses on our city streets, on our interurban highways, and more and more on our farms. With an average of one automobile car or truck to every two or three families the contrast is great between our civilization and that of the ancients, in which long lines of slaves carried on their backs the wealth of that day. Indeed, we have only to go to the Orient of today to see man labor in its simple terms, with little of the multiplication by machinery that characterizes our Occidental world.

In contrast, then, with the Greek civilization of the past or even with Oriental life of today is daily life and work as we know it, and we can clearly see that the Anglo-Saxon dominance of industry and commerce is founded largely on coal and iron. It was the steam engine that gave birth to modern industrialism and to modern distribution of the products of industrialism. The centralization of power units, which took place nearly half a century earlier in England than in the United States, resulted in the centralization of industry in factory towns and put large plants in the place of small workshops and home looms. So the industrial change in the century just past was greater than in all the earlier centuries recorded in history. Indeed, the development of industry was so rapid that the industrial scheme changed more in a few years than it had in the 18 centuries since the boy Jesus worked at the carpenter's bench in his father's shop. All this is only the story of the application of mechanical power to the aid of the human worker.

Present Supply of Energy and Its Distribution

The estimates I have already used for last year's utilization of power give a good starting point for our review of the present and future supply of energy. The engineers who are making the special power investigation under the United States Geological Survey figure 125 billion horsepower-hours as last year's output in the United States. Of this total of primary power more than 82 per cent is credited to steam, a little over 15 per cent to water, and the remainder—less than 3 per cent—to internal-combustion engines. As to the uses, the division of this power is, roughly, public utilities 42 per cent; manufacturing industries, not including rented electric power, 28 per cent; and steam railroads, 30 per cent. The statistical basis for these estimates is not all that we might wish, but they show roughly where the energy we use comes from and what we use it for.

[1] Director, United States Geological Survey.

Paper presented at the Fortieth Anniversary meeting of The American Society of Mechanical Engineers held by the Chicago Section at Chicago, Ill., November 22, 1920.

Much of the work that is done for us by these servants is done so far away that we are unconscious of what it involves. At least four of the five slaves in whose work each of us can claim the larger share owe their strength to coal; their power is that of the steam engine turning this wheel and that wheel the country over. Here in the United States our per capita consumption of coal exceeds that of any other country, and we ourselves may sometimes wonder what becomes of the annual 6 tons or more allotted to each man, woman and child. You and I well appreciate how many tons of coal we buy each year for our own household use, but we can only guess in a general way where the rest goes—to the railroads and furnaces and factories. Recently, in speaking to some steel men, I stated the facts of coal distribution somewhat as follows:

The figures of our coal resources, millions of millions of tons, or even the few hundred million tons of our annual output, are too large to be grasped, and it becomes necessary to express the facts in smaller quantities. Roughly speaking, 1000 tons of coal is what a mine worker mines in a year—the measure of what he contributes to the world's work and well-being. This human measure of 1000 tons also has the advantage of being easily visualized as a short train load (20 cars) of coal on its way to serve the varied needs of the consumer, and in our brief review of the subject we may well note first what are these needs—the principal uses of coal, among which this unit of 1000 tons is divided. Broadly stated, the largest use of coal is in furnishing motive power and heat for our industries and public utilities, 350 tons out of every 1000 tons mined going to the boiler house of factory, mill, shop or power plant. But next to these 7 carloads of coal distributed throughout the country are 5 cars, or 250 tons of coal, that the railroads burn for their own use. The domestic demand for coal comes next, 165 tons out of each 1000 tons of anthracite and bituminous coal being used in the homes of the land for heating and cooking. The coke ovens take nearly as much as the homes, or 130 tons; and the rest of our miner's contribution includes the coal for export and bunker use, 60 tons; the 35 tons of coal used in operating the coal mines themselves, which of course does not make up a part of our train load; and the 10 tons that goes to the gas works.

Coming back for a moment to the personal service which we receive from coal through steam, I can perhaps illustrate how close home this service may come and how silently it may be rendered by reference to our electric lights—new only yesterday but commonplace today. Here in a special sense coal is the slave of the lamp. To learn how much coal comes into my house over the wire, I recently reviewed my electric-light bills and converted kilowatt-hours back into pounds of coal, with the result that I found that my household had used $1^1/_5$ tons of coal in a year simply to provide illumination. This annual per capita consumption of 400 pounds of coal for illumination is probably not far from an average figure, for even if my record is high in kilowatt-hours, the Washington central station is much lower in coal consumption than the average station. Nor do our coal requirements for illumination stop in our homes: in Washington, where our streets are far from being "white ways" at night, our street lighting, such as it is, with part electric and part gas lamps, costs each of us 33 pounds of coal and a gallon or two of gas oil each year. If we add to these figures something for the lighting in the buildings where we work, it probably costs each of us considerably more than a quarter of a ton of coal a year for our artificial light—to that extent are we drawing upon the sunshine of another geologic era.

To give perspective to our review of our present supply of energy, let us simply glance at our increasing use of coal. In 1918 we used nearly $6^1/_2$ tons per capita, but a century ago the country's output of perhaps 40,000 tons of coal amounted to less than 8 *pounds* per capita, or hardly more than is used in the central station to furnish my home with light for a single evening. Even fifty years ago when this country was on a coal basis, our per capita consumption had reached only about 1700 pounds, which would mean a real coal shortage today. This rate of increase in demand for coal alone does not make prophecy easy, yet in planning for the future you engineers should perhaps start off with an inventory of the world's supply of energy in the form of flowing water and the two mineral fuels, coal and oil, and, first of all, a glance at the way these are allotted to the continents.

The World's Sources of Energy

One of the by-products of the coöperative efforts by the Government scientific bureaus in aid of our Peace Commission was an inventory of the water-power resources of the world, and this is now being prepared for publication by the United States Geological Survey. It shows that only about one-twentieth of the potential power of the world's rivers has been utilized, and over half of this in North America, with Europe credited with one-third and the rest divided between Asia, South America, Oceanica, and Africa, in the order named. In its potential resources, however, Africa ranks not last but first; it has over 40 per cent of the world's supply of water power and is followed in turn by Asia, North America, South America, Europe and Oceanica.

In the division of coal resources among the continents, at least of the better grades of coal, similar inequalities are seen: North America has more than half, Asia about a quarter, Europe a sixth, and the rest is divided between Oceanica, Africa, and South America, in the order named.

The present realization of the world's interest in its supply of petroleum has led to similar estimates of the recoverable resources, first in the United States and then in other countries; and whether we dignify these quantitative measurements of oil reserve by terming them official estimates or describe them by calling them scientific guesses, they are the best we have, and they will serve fairly well in guiding national and international action.

It may be noted that the United States Geological Survey's estimate of the petroleum resources of the world shows that the distribution, while unevenly balanced among nations, is evenly balanced between the eastern and the western hemispheres, although the northern hemisphere appears to have at least five times as much oil as the southern. This preponderance of the oil supply of the northern hemisphere should, however, be discounted by a fact and a possibility; the land area of the northern hemisphere is three times that of the southern and the larger unexplored areas are in South America, Africa, and Oceanica.

Accepting the Stebinger-White distribution of the world's oil reserves, we may roughly set down the continents in order of wealth in oil in North America, Asia, South America, Europe, Oceanica, and Africa. In terms of regional distribution, more than half the world's oil reserves are believed to be concentrated in two intercontinental areas; one of these oil-rich provinces includes the North American and South American countries bordering the Caribbean Sea, and the other includes the countries of western Asia and southeastern Europe, with the Caucasus as an axis. On these two areas, then, each comprising only about 2 per cent of the earth's surface and each containing about 30 per cent of the world's future supply of oil, is focused the attention of the great nations that most need oil.

The resources of the world's oil shale are far too large to be lost sight of as a substitute source of oil. The United States alone is believed to possess deposits of oil shale that contain at least ten times as much oil as there is natural petroleum available in North America, but oil won by mining and distilling these shales, situated in the interior of a continent, cannot enter the world's markets as labor-cheap as the petroleum that flows from Mexican wells close to the coast. Such resources must therefore be regarded as a rear line of economic defense and as a source of power that will be of greater value to other generations than to this, even if a more general utilization of oil shales begins in the near future. No other continent is known to have resources of oil shale at all comparable with those of North America.

In this rapid review of the world's sources of energy we see North America taking first rank among the continents, with Asia a close second and Europe a poor third, although we should remember that Europe has a much smaller area than either of the other two.

Relative Importance of Coal, Oil and Water as Sources of Energy

Next, in considering how the world may best manage its ever-increasing power load, some aid may be found in a few comments on the differences between these three sources of energy—water, coal, and oil. Man has learned how to harness flowing water with

The Development of Artillery Materiel

By MAJOR G. F. JENKS,[1] WASHINGTON, D. C.

The first portion of this paper is a consideration of artillery-materiel development before the war and the effect of the war upon it, both in this country and abroad. Mechanical traction, it is stated, permits the increased weights required for long-range artillery; increased speed permits rapid strategic concentration of artillery; high-grade steels permit greater power in guns. All of these factors are important to the artilleryman. The efforts of the ordnance engineer since the war have been devoted for the most part to the development of pieces of greater range, greater elevation and greater mobility. The author points out the lines of development which are being followed, outlining gun-construction methods now in use and showing the value of the research work now being carried on. He describes different models of howitzers, guns and mounts, and discusses some of the details of design of recuperators, carriages, and sighting systems. The paper closes with a survey of the development of antiaircraft materiel and coast-defense work.

ALL wars have stimulated the development of the implements of warfare. Especially during the past war have the minds of engineers been fertile. New implements of war have been conceived and developed. Old ones have been given the supreme test and found capable of further development. Of the problems arising from the war none is more important or more interesting than the development of artillery matériel. In analyzing it a brief consideration of its state before the war and the effect of the World War upon it, both in this country and abroad, is necessary.

The field gun with which our service was equipped prior to 1917 was developed about 1902 to meet the demands for a stable gun carriage—one in which the aiming of the piece was not disturbed by the shock of firing. No marked developments in design then took place until the invention of the split-trail carriage, by which large increase in both traverse and elevation of the piece was made possible. In 1912 the Ordnance Department initiated the design of such a carriage, which, after exhaustive proving-ground tests, was put into production in September, 1916.

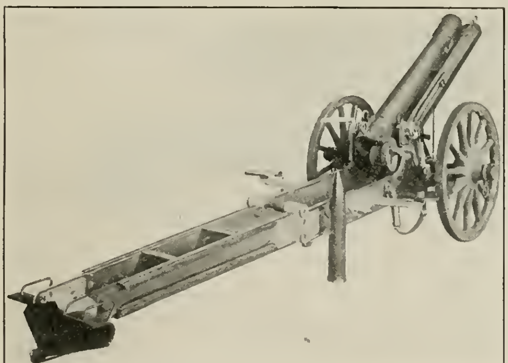

Fig. 1 75-mm. Pack Howitzer, Model of 1920

The design of howitzers and medium-caliber guns was limited by road conditions in this country. In these pieces power was sacrificed to obtain the necessary mobility. It had been considered impracticable to use heavy siege guns and howitzers on this continent and none had been provided for our troops.

For war manufacture French and British designs were adopted for all calibers of guns and howitzers except the 4.7-in. field gun. The French 75-mm. field gun was put into production because the American split-trail carriage had not been thoroughly tried out in service and the British 75 was ordered because production facilities were available.

The United States entered the war with neither an adequate engineering force to develop new designs nor a trained production force to organize manufacture. It had merely a handful of matériel and practically no facilities to produce it. Our allies not only furnished us matériel, but gave us their designs and detail drawings

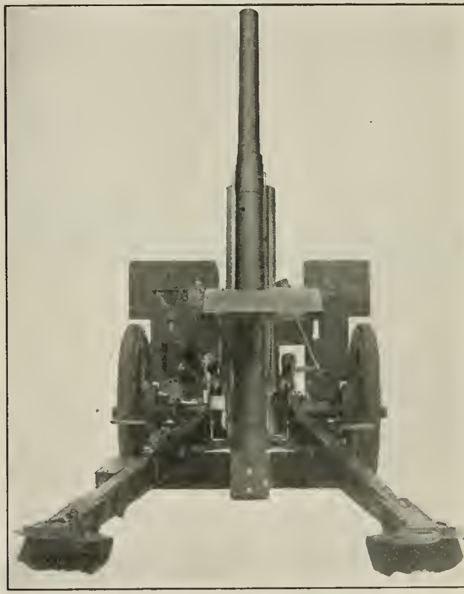

Fig. 2 75-mm. Gun, Model of 1920

and their design and production engineers to assist us in organizing production. Most of our own engineering talent was required to solve the problems of production. Considerable new development work was initiated during the war. Although working under war pressure, time was too short to secure results. Had the war continued, some real development work might have been accomplished with the large, earnest organization built up during the war.

On the other hand, much was accomplished abroad in the development of artillery matériel. The French developed long-range siege artillery and were about to bring out the design of a new field piece. They also succeeded in increasing the mobility of siege guns. The British gradually improved the range characteristics of their artillery during the war and had under manufacture an excellent design of a new field gun.

The Germans easily ranked first in the development of artillery during the war. They developed and manufactured greatly improved pieces of all calibers. They recognized the value of range, not only in the design of more powerful guns of a given caliber, but also in mounting these guns on carriages so that their maximum range could be secured. By the use of these pieces in the spring offensive in 1918, the Germans caused much concern to the allied artillery commander. This statement does not refer to the "big Bertha" fired against Paris, which was of little or no direct military value.

One well-known American artillery commander reported under date of October 8, 1918, after remarking on the changed German tactics made possible by the introduction of their improved artillery in the spring of 1918:

[1] Ordnance Department, U.S.A. Mem.Am.Soc.M.E.

Paper presented at a meeting of the Washington Section of The American Society of Mechanical Engineers at Washington, D. C., December 2, 1920.

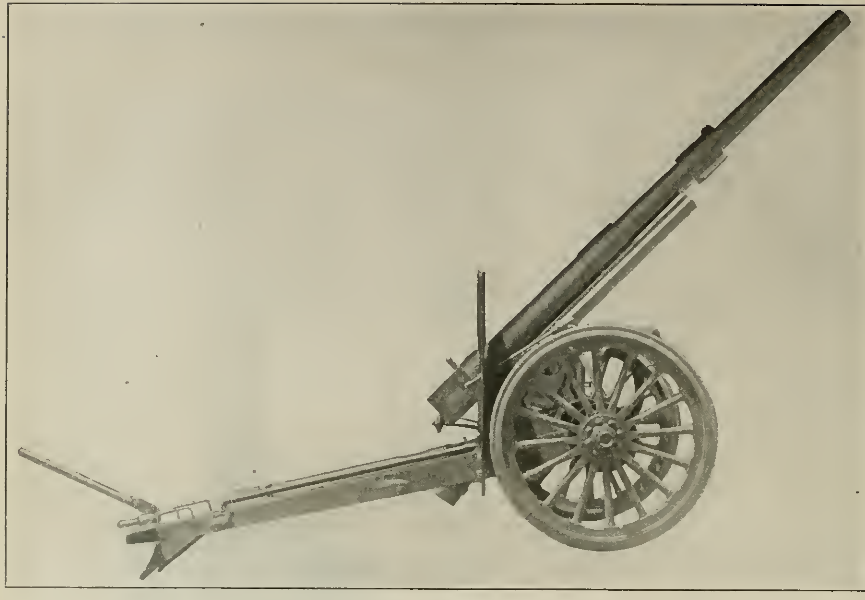

Fig. 3 75-mm. Gun, Model of 1921

Under these circumstances, the trench mortars and short-range antiquated French guns that we install and supply with ammunition with so much labor, are of little or no use. They pound an empty space and we cannot move them forward over No-Man's Land and supply them with ammunition...... For the present phase of the war, then, range is a most vital consideration. The Germans have increased the range of their guns. ... To contend with these German guns, or in other words, to meet the condition, in the existing phase of the war, we must have guns and howitzers of long ranges.

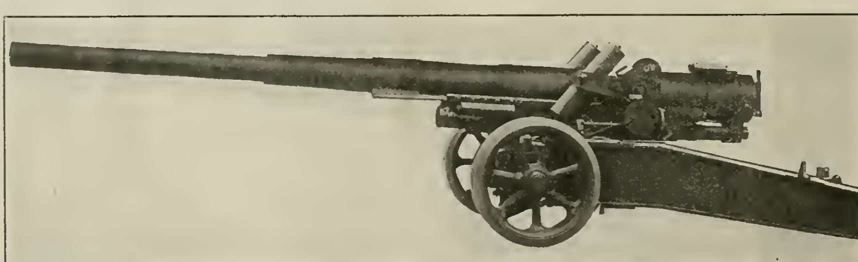

Fig. 4 155-mm. Gun, Model of 1920

Prior to the war the marvelous progress in the mechanical arts caused by the development of the gas engine had had no appreciable effect upon the design of artillery matériel. The field piece had been conceived in terms of the horse, the mountain howitzer in terms of the pack mule. Very little progress had been deemed possible as the horse was a fixed quantity. But the perfection of the gas engine has removed the horse as a limiting factor. The development of the automobile industry has given us high speeds of vehicle propulsion, and a demand for and supply of alloy steels of high physical properties. All these factors are important to artillerymen. Mechanical traction permits the increased weights required for long-range artillery. Increased speed permits rapid strategic concentration of artillery; high-grade steels permit greater power in guns.

Development of the Long-Range Gun

After the armistice the sentiment of our artillerymen was unanimously in favor of pieces of greater range, greater elevation, and greater mobility. This sentiment found expression in the reports of the various service boards and especially in that of the Westervelt Board appointed by the War Department, December 11, 1918. The report of this Board was approved by the Chief of Staff on May 23, 1919, and its recommendations have become the fundamental specifications for mobile artillery matériel.

The efforts of the ordnance engineer since the war have been devoted mostly to the development of design under the Westervelt Board program. Under that program the same calibers of pieces as used during the war will be developed, but they will have greater range, greater flexibility of mount, and greater mobility.

The longer range will be attained partly through ammunition development, but also by increase in the length and muzzle velocity of the gun. As mobility requires lightness, the weight of the gun must be reduced as much as possible. To secure this, three lines of development are being followed: first, by using material of higher

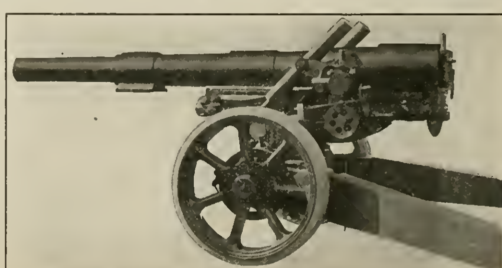

Fig. 5 155-mm. Howitzer, Model of 1920

second, by wire-wrapping the tube; and third, by the "auto-frettage" process.

The nickel steel specified during the war was of the following physical qualities: elastic limit, 65,000; tensile strength, 95,000; elongation, 18 per cent; contraction, 30 per cent. Gun forgings for some experimental matériel are being made of nickel-chrome steel with the following physical qualities: elastic limit, 80,000; tensile strength, 105,000; elongation, 18 per cent; contraction, 30 per cent. Such forgings have been produced, but many problems have arisen in their production. Some of the first produced were extremely brittle and under stress behaved like cast iron. One small gun which seemed to be made of excellent metal according to the usual methods of test, failed under less-than-service interior pressure. Impact tests developed the fact that an improper heat treatment had been given. This brittleness has apparently been overcome by quenching the forging from the "draw." But, although impact tests have shown excellent results, yet the metal is full of internal stresses and the gun finisher experiences considerable difficulty in keeping the bore straight. What effect these internal stresses will produce at the proving ground is not known. Laboratory tests made upon the steel of captured German guns indicate that this kind of steel was used successfully and that it was tough, free from internal stresses, and remarkably uniform. Much work still remains to be done in developing a satisfactory steel of this quality.

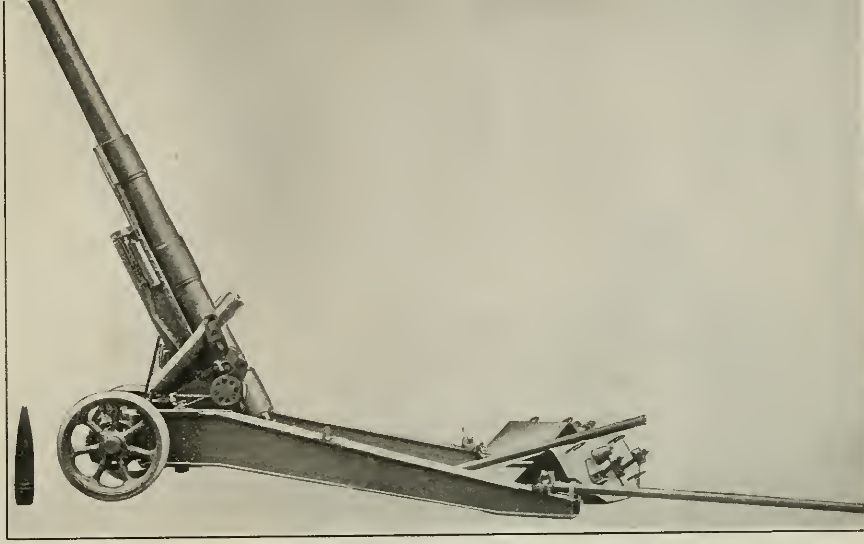

Fig. 6 8-in. Howitzer, Model of 1920

No new problems are involved in the construction of the wire-wrapped gun. By the use of wire, lower-grade metal can be utilized in the forgings. Guns made by this process are slightly heavier than those made of chrome alloy steel. At present, however, it is a more conservative method of construction.

In the auto-frettage method of construction the gun is built up of a few pieces of steel of medium physical qualities. The walls of the gun are internally stressed beyond their elastic limit by internal hydraulic pressure. The condition set up is similar to that produced by the shrinking process. It can be applied to the whole gun, whereas the effect of shrinkage is limited to the hooped portion. For a given strength thinner walls are sufficient. This assures minimum weights. The process is also a cheaper one than either the built-up or the wire-wrapped method of construction.

Gun-Construction Research

A research program has been undertaken at Watertown Arsenal to determine the laws underlying the auto-frettage process. One 155-mm. howitzer is now ready for auto-fretting. Although others have constructed and tested guns built up by auto-frettage, our program covers an investigation of the principles and theory rather than hasty proving-ground tests.

Much research work still remains to be done in determining the proper form of rifling, the effect of variation of elements of the bore upon the life of the gun, the production and heat-treating of metals used in gun construction, and in checking the fundamental formulas of gun design. Our knowledge of the theory of gun construction is rather unsatisfactory.

For pack howitzers and field and siege pieces of 75-mm. and greater caliber, the hydropneumatic recuperator is being employed. The St. Chamond type is used for 75-mm. and 105-mm. calibers and the Filloux type for 4.7-in. to 8-in. calibers. No new developments have been made in these types since the armistice. They have been merely adapted to meet the new conditions imposed.

During the war great difficulty was experienced in the production of recuperators. Because of the use of oil and air under high initial pressure extremely fine workmanship was required in the finishing of the bore of cylinders and the manufacturing of pistons. If possible a recuperator which is simpler to manufacture should be developed.

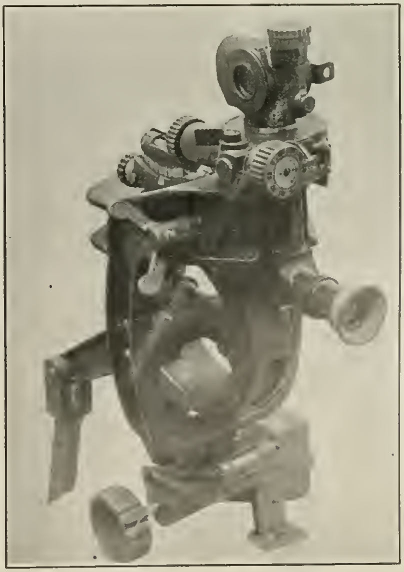

Fig. 7 Sight for 75- and 105-mm. Materiel, Model of 1920

Such a development is being carried on. In this system the air is confined in a metal bellows. Complex pistons to hold pneumatic and initial hydraulic pressures are eliminated. Such a system offers much simpler production problems.

Carriage Developments

Two independent lines of carriage development are being pursued: the wheel type and the caterpillar type. Common desirable charactristics are high elevation, wide traverse, a minimum depth of pit for clearance of recoil parts at high elevation, and, of course, stability at all elevations.

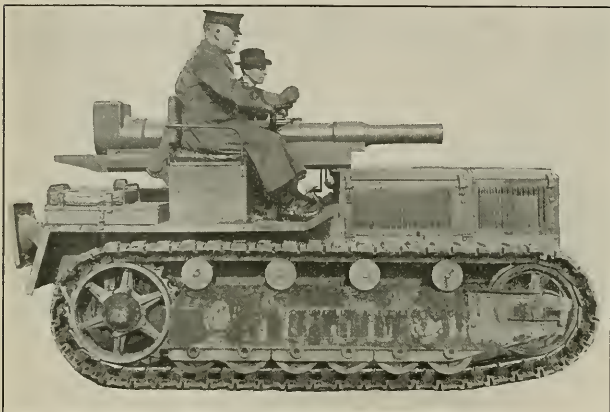

Fig. 8 Self-Propelled Caterpillar Mark VI for 75-mm. Gun and for 105-mm. Howitzer, Model of 1920

The condition of high elevation and minimum depth of pit has necessitated placing the center of trunnions of the tipping parts in rear of their center of gravity, and equalizing the force required to elevate and depress by an equilibrating system. In most pieces it requires variable recoil. Although the equilibrating system adds weight and complexity to the gun carriage, yet it tends to improve the accuracy of fire as the pressure on the elevating gears does not change in direction during the recoil. This should keep the backlash of gearing in the same direction and reduce the jump.

Bringing the center of rotation of the gun to the rear and the use of variable recoil also permits lowering the axis of the gun. This is advantageous in permitting lightness of construction and shortening the trail.

Wide traverse has resulted from the use of the split trail at the expense of weight and simplicity of construction. The split-trail 75-mm. matériel weighs about 700 lb. more than the box-trail matériel. This is due partly to the greater elevation—80 deg. compared with 40 deg. It is believed that the simpler, lighter and more rugged single-trail is by far the preferable design for the 75-mm.

The provision for elevating pieces beyond that required for maximum range is causing complication of design and increased weights. The bottom carriage must be built out farther from the axle to permit clearance at high elevations. This is expensive in weight.

The Westervelt Board report contemplates a gun and a howitzer mounted on the same carriage. This simplifies production and supply, but it complicates the design of the carriage. It is difficult to secure the same reactions in the carriage from both gun and howitzer. For example, the 4.7-in. gun matériel is heavier than it need be because the 155-mm. howitzer demands a heavier carriage. It appears preferable not to attempt the use of exactly the same carriage for both pieces, but merely to make them as nearly alike as practicable. The ideal of the artilleryman is the reduction of the number of calibers to a minimum and the standardization of mounts. The desirability of such a program is apparent to the supply department charged with production and maintenance. However, the mission of the piece—not the desirability of standardization—must fix its characteristics.

In the development of the wheel-type mount it is probable that in some cases we have overstepped the boundary of conservative design, and that later we will be content to reduce the severity of some of our specifications in order to simplify and lighten our designs. However, the present designs incorporate characteristics that seem desirable. Until pieces embodying them are constructed and tested, the engineer will not be content that these characteristics are feasible, and the service will not be satisfied that they cannot be embodied in their matériel.

Sighting Systems

No marked development is being attempted in sighting systems. Of course panoramic sights or suitable telescopic sights will be used for all calibers. The field-gun sight follows that developed for the 75-mm. model-of-1916 matériel and the sight for heavier guns will be a modified quadrant sight like that used on the 155-mm. howitzer, but with a panoramic sight. For accompanying fire-control instruments only minor improvements are now contemplated.

Caterpillar Mounts

In the war models of caterpillar mounts, little attention could be given to reduction in weight and to refinement in design. The possibilities of development of these types of gun mounts should not, therefore, be judged by the matériel built under war contracts, nor even by that now being constructed. Especially, such essential characteristics as accessibility of parts for maintenance and elimination of mechanical weakness in details of construction must be worked out by experience. In considering any model the possibilities of perfecting the design into a desirable machine must be given the greatest weight. Mechanical imperfections can be eliminated.

Caterpillar-mount development is now proceeding along two lines: first, the track-laying type found in tractors; and second, a combination wheel and track-laying type in which the mount may be operated on wheels on good roads, or on tracks where road conditions are bad.

Fig. 9 Self-Propelled Caterpillar (Christie) for 155-mm. Gun, Model of 1918

Both types are self-propelled and have similar gun characteristics. Weights are about the same and speeds are similar. Because of the promise of both types, light and heavy-gun pilot matériels of both are being built. The 75-mm. gun and 105-mm. howitzer matériels are being designed and built by the Holt Caterpillar Company and by the Front-Drive Motor Company. Good compara-

Some 155-mm. gun caterpillar mounts designed by Mr. Christie of the Front-Drive Motor Company are nearing completion for a service test. Six caterpillar mounts for the same gun made according to a Holt design are now in the hands of the service. No decision should be drawn, however, from a comparative test of these two current models, as the Holt Company is now designing and constructing an improved mount. For the 4.7-in. gun and 155-mm. howitzer the Holt type only is being developed at this time.

The specifications of the Westervelt Board report for range of the heavy howitzer and gun for caterpillar mounts are very severe. The howitzer required is about the same length in calibers as the 155-mm. gun used during the war, while the gun is the same as for railway mounts. While it is possible to handle such guns in the field on self-propelled or trailer caterpillar mounts, yet it appears probable that the service prefers greater mobility and ease of getting into firing position at the expense of range. No decision has yet been reached in the characteristics of these pieces.

The ideal traverse as expressed by the Westervelt Board report is 360 deg. This is being secured only in anti-aircraft mounts in which the gun is pivoted on a pedestal. Mechanism will be provided in caterpillar mounts to traverse the whole mount by hand power. Of course this is a compromise, but the best practicable at this time. Mounting guns on a pivot like that in the anti-aircraft mount requires increased height of trunnions and heavy mounts—both undesirable features.

Infantry Howitzers

In the infantry-accompanying howitzer an attempt is being made to develop a piece which can be used either as a direct-fire gun aginst tanks or as a howitzer, taking the place of the 3-in. trench mortar. Guns of the 1.8-in. and 2.24-in. caliber are under construction. The caliber suitable for an anti-tank gun is too small for an efficient howitzer projectile. It is believed more logical to recognize the difference in mission of the two pieces and to develop efficient designs for both missions. The piece will be capable of being broken up into man loads.

Anti-Aircraft and Coast-Defense Work

For anti-aircraft matériel the development of a satisfactory fuze for high-muzzle velocities is a limiting factor. Two calibers

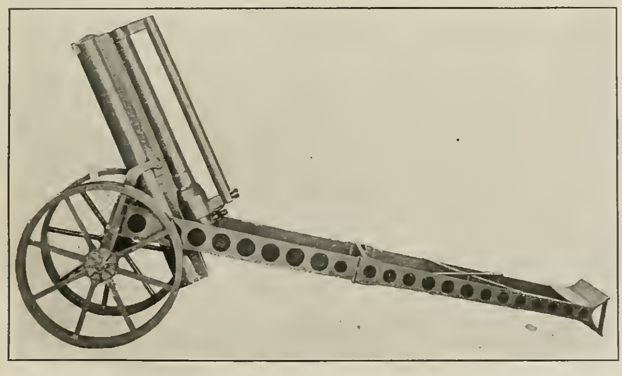

Fig. 10 2.24-in. Infantry Howitzer, Model of 1920

of guns are being developed, 3-in. and 4.7-in. The mounts will be capable of being leveled on the caterpillar base. The sighting system permits the application of azimuth and elevation corrections and superelevation without disturbing the pointing of the sight. Compressed air will be used for loading. In the heavier gun a muzzle brake will be developed in order to lessen the load on the recuperator. With other guns almost 85 per cent of the recoil energy has been absorbed in a muzzle brake, but only about half that efficiency is expected in this case. For anti-aircraft work,

For coast-defense work the 16-in. 50-caliber gun and the 25-caliber 16-in. howitzer are now standard. Only one disappearing carriage for the gun is being built. Both guns and howitzers will be mounted on barbette carriages capable of 65 deg. elevation. Hydropneumatic recuperators permit this use of increased elevation. The

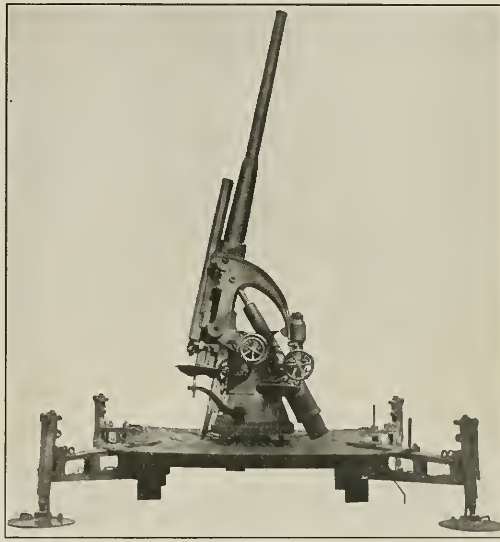

Fig. 11 3-in. Anti-Aircraft Gun Mount, Model of 1920

14-in. 50-caliber gun is also standard for coast defense. For it a new type of railway mount suitable for both field and coast-defense work is under manufacture. For coast defense a concrete foundation permits of 360 deg. traverse, while for field work traverse can be obtained from a curved track. The same railroad mount will take the 16-in. howitzer. A railway mount for a 12-in. 20-caliber howitzer is now under test. The howitzer is capable of all-around fire from the car body. The same type of carriage can be developed for an 8-in. 50-caliber gun, but lack of funds has not permitted the undertaking of this work. Studies have not yet advanced sufficiently to warrant a definite statement as to whether it is practicable to mount guns of larger caliber than 14-in. on railway mounts.

The present tendency is toward more powerful guns for seacoast defense. Some gain in power may be obtained by increasing the length and muzzle velocity, but the logical step is an increase in caliber. If economy is to be exercised in the construction of fortifications, they should be armed with guns which are at least two decades ahead of naval armament in development.

A large problem is the development of fire-control matériel for heavy coast guns. Range-finding and observing instruments set up in the neighborhood of the battery are insufficient. Guns are now capable of reaching targets which are below the horizon to our present fire-control stations. The observer is forced into the air, where the difficulties of leveling and orienting instruments are tremendous. An observation instrument leveled and oriented by gyroscopes is nearing completion. It is rather complex and no hopes can be given as to its ultimate utility. In the development of accessory instruments good progress is being made.

This rapid general survey indicates the enormous extent of the field in which artillery development work is required. It is impossible in a limited paper to indicate the depth of the program by touching upon the numerous problems which the research engi-

neer must solve in the laboratory. Needless to say, years of intensive work are required. As the stock of artillery matériel on hand is sufficient for any present needs, time should be available to perfect matériel and thoroughly test it before production should be required. Only an engineer familiar with the cost in the past of putting types of matériel into production before the design has been carefully tested at the proving ground and in the field can realize the enormous saving to the Government of fully developing artillery matériel on a small scale before equipment of armies is required.

Factor Which Determine Wheel-Wearing Action—Laws Relating to Draw-In and Traversed Cuts—Production Costs

By W. H. CHAPMAN,[1] WORCESTER, MASS.

[This paper comprises a study of the laws involved in cylindrical grinding and an analysis of grinding action both for draw-in cuts and traversed cuts. In view of the effect of wheel wear on grinding efficiency, formulas are derived for wheel wear in terms of known variables such as grain size of wheel, work speed, wheel speed, feed, etc. By calculating values for wheel wear for different conditions and comparing them with production figures calculated under the same conditions, a proper selection of wheels may be made.

The fact that the expense due to wheel wear comprises but a small item in the total cost of grinding, however, may lead to wrong conclusions if this is made the controlling factor. In the latter part of his paper, therefore, the author discusses the subject of production costs and the various factors that should be considered in securing the highest possible grinding efficiency.—Editor.]

In Fig. 1 is shown a section of wheel and work with the elements greatly enlarged. The grain paths across the work are indicated and a shaded area indicates the shape of a single chip. The grain paths are shown as straight lines tangent to the feed circle. Actually these paths are not straight lines but are epicycloidal curves. However, within the limits of probable dimensions which are actually involved in any cylindrical grinding operation, a graphical layout of the grain paths on a large scale (say $^1/_4$ in. = 0.0010 in.) will show that these curves are so nearly straight lines that the error is negligible. The mathematical relations are greatly simplified by this assumption. By actual trial it was found that there was seldom over 2 per cent difference in the values of maximum chip depth obtained by the use of the *actual* and the *assumed* forms of grain path.

Wheel-Wearing Action

The three factors to be considered as determining wheel-wearing action are (1) the frequency with which the grain is applied, (2) the average grain depth of cut as indicated by the chip dimensions, and (3) the kinetic energy of the grain due to its mass and velocity.

[In his complete paper, the author here discusses the three factors mentioned and derives the formulas given below for grain depth of cut and for wheel wear, using the following notation:

N = r.p.m. of wheel
V = surface speed of wheel, ft. per min.
u = work speed in ft. per min.
R = wheel radius in inches.
r = work radius, inches
f = depth of cut, inches on work radius
μ = interval between grains, inches
S = radius of feed circle = $r - f$, inches
G = maximum depth of chip, inches.]

Frequency of application depends upon the revolutions per minute of the wheel. Work done is measured by the dimensions of the chip removed by each grain and the total number of chips removed. Kinetic energy is proportional to the mass and square of the velocity of the cutting particles.

Frequency of application of the grain $= N = \dfrac{12V}{2\pi R}$, and volume of wheel wear $= \dfrac{12V}{2\pi R} \times 2\pi R$. Therefore wheel wear is directly proportional to $12V$; or dropping the constant, is directly proportional to V.

The formula for grain depth of cut, as derived in the complete paper, simplified by the omission of inconsequential terms, is

$$G = \frac{\mu u}{V}\sqrt{\frac{2f}{r}} \text{ (approximately)} \qquad [1]$$

From this it is deduced that grain depth of cut varies directly with grain interval, work speed, and square root of radial feed; and inversely with wheel speed, and square root of work radius.

The kinetic energy of the cutting particles increases with the square of the velocity.[1] For a certain depth of cut the resistance of the work to the grain is very nearly proportional to this depth, as the cuts are very small, even when compared to the total size of the grain. Theoretically, for some low velocity the kinetic energy of the grain should just equal the energy required to remove the chip (the feed would be reduced to maintain constant grain depth of cut under reduced wheel-velocity conditions) and wheel wear would be caused without any chip being removed up to this point. Actually the bond strength is always sufficient to prevent this condition. Our assumption is then clear that:

Wheel wear varies inversely with the *surplus* kinetic energy of cutting particles and is inversely proportional to *effective* wheel surface velocities (wheel speed minus work speed).

We are now prepared to combine factors.

a Wheel wear is proportional to the wheel speed, or to V.
b Wheel wear is proportional to the grain depth of cut, as expressed in Formula [1].

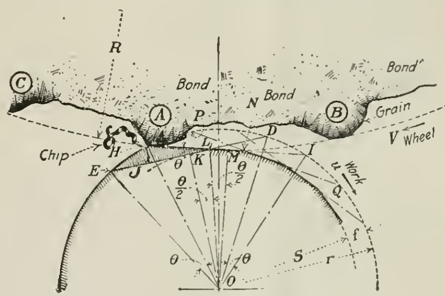

Fig. 1 Diagram Illustrating Cutting Action

c Wheel wear is inversely proportional to surplus kinetic energy of the cutting particles, or proportional to $1/(V-u)^2$. The term u is usually negligible as compared with V and it may therefore be assumed that $1/V^2 = 1/(V-u)^2$.

From these relations, *a*, *b* and *c*, an index of wheel-wearing action (WW_1) due to grinding (where the wheel face is free-cutting) may be expressed as follows:

$$WW_1 = V\frac{\mu u}{V}\sqrt{\frac{2f}{r}} \times \frac{1}{V^2}$$
$$= \frac{\mu u}{V^2}\sqrt{\frac{2f}{r}} \qquad [2]$$

Laws of Grinding for Draw-In Cuts

From this expression we may derive the following laws of cylindrical grinding, operative *within the usual limits of speeds and dimensions.* For straight-in (draw-in) cuts a free-cutting wheel will wear according to the effect of wheel-wearing action as follows:

a Wheel-wearing action increases directly as:
1 Grain interval (grain size—inversely as grade)
2 Work speed (surface)
3 Square root of diametral cut (feed).

b Wheel-wearing action increases directly as the following are decreased:
1 Square of wheel speed (surface)
2 Square root of work radius.

---

[1] Norton Co.

Abstract of a paper presented at the Annual Meeting, New York, December 1920, of The American Society of Mechanical Engineers. All papers are subject to revision.

[1] See Selection of Grinding Wheels for the Foundry, *Grits and Grinds*, Jan., 1915, The Norton Company, Worcester, Mass.

A soft wheel is more susceptible to wheel-wearing action than a hard wheel and will more nearly follow the theoretical conditions. It is therefore more free-cutting and will cut more nearly the full chip than a hard wheel. There is consequently a gain in production as wheels of softer grades are used, all other conditions remaining constant, up to the point where the chips are geometrically perfect for a given condition of speeds and dimensions. It is clear from this standpoint that the softest possible wheel should be used. High wheel speeds up to the safe limit are of course necessary if the soft wheels are to perform in a satisfactory manner.

To show the practical application of Formula [2] for wheel-wearing action (Index of Wheel Wear), Table 1 is given.

In column 1 of the table are the work speeds provided on a recent grinding machine, given in order so that actual values can be experimentally obtained to check with the theoretical. In the succeeding columns are two series of values as follows:

1 Following the term "Production" are *approximate* values for cubic inches of metal removed per minute for a wheel 1 in. wide. These were calculated by the formula, Production = nominal work diameter $\times \pi \times$ r.p.m. $\times$ depth of cut (assumed to be 0.0005 in.), which gives values slightly less than the true values.

2 Following the terms "Wheel Wear" are values of the *actual* wheel wear obtained by multiplying the Index of Wheel Wear, calculated by Formula [2], by a constant derived by experiment. This constant is for convenience expressed in the form 1800×10^4.

Sample Calculation. In Formula [2] assume:

u = 53 r.p.m. = 13.9 ft. per min.
r = $1/2$ in. (work diameter 1 in.)
f = 0.0005 in.
V = 6000 ft. per min.
μ = 0.05
R = 9.0 in. (wheel radius)

Substituting,

$$WW_1 = \frac{0.05 \times 13.9}{36{,}000{,}000}\sqrt{\frac{0.001}{0.5}}$$
$$= 0.0000000196 \times 0.047 = 9212 \times 10^{-13}$$

Multiplying by constant given above (1800×10^4),

WW_1 = 0.0166 cu. in. per min. for wheel 1 in. wide.

The corresponding "Production" in Table 1 is 0.0835 cu. in.

It will be seen that the wheel-wear values increase rapidly as work speed increases. The value 0.0166 for work of 1 in. diameter at 53 r.p.m. becomes 0.1040 for work of 4 in. diameter at 167 r.p.m. The same wheel cannot be properly used for both cases, as one sufficiently soft to cut freely in the first case would wear so fast as to be nearly useless in the second case. However, where wheel-wear values are nearly the same we may expect the same wheel to act properly. For instance, a wheel suitable for 1-in. work at 138 r.p.m. wears at the rate of 0.0433 cu. in. per min.; and one suitable for 4-in. work at 72.5 r.p.m. wears at the rate of 0.0450 cu. in. per min. In all probability one wheel would serve for both.

Selection of Wheels for Draw-In Cuts

From Table 1, and by experimental tests with various wheels, certain ranges of wheel-wear values may be found which correspond to definite grades of wheels of suitable grain size and abrasive for the material to be ground. Once this is done, the selection of proper wheels is no longer a question of guesswork, as wheel-wear indices may be computed for any set of conditions and the proper wheel selected. The question of the variation in wheels has been reduced to a point where it no longer can be a very large factor, and we may always change our speeds or feeds to correct the action in the proper direction if we understand the laws which have been previously pointed out. As an example of the possibilities of wheel selection, it has been found that for a certain machine the following wheels (Norton system of grade) are suitable for straight-in cuts on mild steel:

Wheel Designation		Wheel-Wear Values, Table 1
36 or 46 J	for values from	.0150 to .0250
36 or 46 K	for values from	.0250 to .0350
36 or 46 L	for values from	.0350 to .0450
36 or 46 M	for values of	.0450 and higher

Use no wheels harder than M. For hard materials use a grade softer and No. 60 grain. These values are for straight-in cuts only.

Influence of Feed. As an example of the effect of doubling the feed, let us assume the conditions as above, except that the feed is increased to 0.001 in. (on radius).

$$WW_1 = \frac{\mu u}{V^2}\sqrt{\frac{2f}{r}} = \frac{0.05 \times 13.9}{36{,}000{,}000}\sqrt{\frac{0.002}{0.5}}$$
$$= 1240 \times 10^{-13}$$

Wheel wear = $1800 \times 10^4 \times 1240 \times 10^{-13}$ = 0.0224 cu. in. per min. per inch of wheel face. Production is approximately doubled and

$$\text{Wheel-wear increase} = \frac{0.0224 - 0.0166}{0.0166} \times 100 = 35 \text{ per cent.}$$

This indicates how advantageously an increase of feed operates to obtain increased production (up to the limit of grain penetration). If we had doubled work speed we would simply have doubled both production and wheel wear.

TABLE 1 COMPARISON BETWEEN WHEEL WEAR AND QUANTITY OF METAL REMOVED AT DIFFERENT WORK SPEEDS

Work Speed in r.p.m.		Work Diameters 1 in.	2 in.	3 in.	4 in.
53	Production	0.0835	0.1670	0.2500	0.3340
	Wheel Wear	0.0166	0.0236	0.0290	0.0334
72.5	Production	0.1140	0.2280	0.3420	0.4560
	Wheel Wear	0.0226	0.0319	0.0390	0.0450
87	Production	0.1370	0.2740	0.4110	0.5480
	Wheel Wear	0.0273	0.0387	0.0475	0.0546
101	Production	0.1586	0.3172	0.4758	0.6344
	Wheel Wear	0.0316	0.0448	0.0540	0.0635
138	Production	0.2160	0.4320	0.6480	0.8640
	Wheel Wear	0.0433	0.0612	0.0645	0.0865
167	Production	0.2620	0.5240	0.7860	1.0480
	Wheel Wear	0.0522	0.0740	0.0910	0.1040

Wheel diameter 18 in.; surface speed, 6000 ft. per min.; diametral feed per work revolution (automatic feed), 0.001 in.; grain of wheel, 6646 Alundum; material, mild machinery steel.

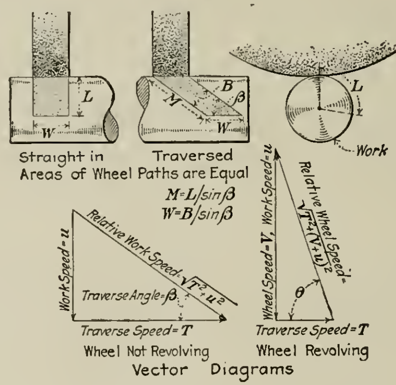

Fig. 2 Speed Relations between Work and Wheel

Traversed Cuts

The most important development in recent grinding machines is the recognition and utilization of the fact that overall operating efficiency for traversed cylindrical work *increases* as *traverse speeds are increased*. (This assumes that for a given traverse speed, width of wheel and revolution of work are so related as to cause the cutting face to just cover the lead of the work.)

Referring to Fig. 2, let

W = width of wheel face
L = length of projected arc of rotation of work
M = actual length of path of traversed cut
B = actual width of path of traversed cut
β = traverse angle

Then $B = W \sin \beta$; $M = L/\sin \beta$; areas $W \times L$ and $B \times M$ are equal. Wheel width of cut is proportional to W for straight-in cut, but reduced to B for traversed cut.

traverse angle. This relative increase does not appear in the projected (end view) relations. As these alone affect individual grain depth of cut, we have gained in relative work speed to get over the longer path M so as to cover the same area in the same time on a narrower width, B, *without* increasing grain depth of cut.

Now if the wheel rotates, each grain cuts across the work at an angle θ, resulting from speed relations shown by Fig. 2 (vector diagram for rotating wheel). Then the individual grain paths are at a much steeper angle than the wheel path to the axis of work rotation, but we have gained in relative wheel speed *without* increasing individual grain depth of cut. Our wheel width of cut is also reduced by a slight amount proportional to $\sin \theta$, which is of course much less than the reduction before the wheel was rotated. The net result is a reduction in wheel stress proportional to $\sin \theta$ and an increase in work speed proportional to $\sin \beta$, *without* increase in grain depth of cut.

The "head resistance" against the wheel as a whole is reduced by the $\sin \beta$ factor, while wheel width of cut is reduced by $\sin \theta$. These both directly affect wheel wear. For traversed-feed conditions our grain depth of cut remains the same as in straight-in feeds, but wheel wear is reduced in the proportion of $\sin \beta \times \sin \theta$.

If T = traverse speed, V = wheel speed, u = work speed, then

$$WW_1 = \left(\frac{u}{\sqrt{T^2 + u^2}}\right)\left(\frac{V + u}{\sqrt{T^2 + (V + u)^2}}\right)\left(\frac{\mu u}{rV^2}\right)\left(\sqrt{2rf}\right) \ldots [3]$$

In practical cases the second term will be so nearly 1 that it may be neglected. It is evident that T affects the quantity appreciably only when u is kept relatively low. This indicates that a wide wheel should be used to get the effect of reduced wear for a given production, traversing as rapidly as possible. The above formula assumes no overlapping of the cut.

Now by making assumptions and neglecting values whose effect is so small as to make no appreciable difference for purposes of comparison, we reduce the expressions for WW_1 exactly as we did in the case of straight-in feeds and obtain:

$$\text{Index of wheel wear } WW_1 = \frac{\mu u}{V^2}\left(\frac{u}{\sqrt{T^2 + u^2}}\right)\sqrt{\frac{2f}{r}} \ldots\ldots [4]$$

Laws of Grinding for Traversed Cuts

From this it is evident that for traversed work:

a Wheel wear increases directly with the work speed

b Wheel wear decreases directly as the decrease in the quantity which we term "traverse factor," which is work speed divided by the square root of the sum of the squares of traverse and work speeds

c Wheel wear decreases directly as square of wheel speed increases

d Wheel wear decreases directly as the square root of the work radius increases

e Wheel wear increases directly as the square root of the feed increases.

The value $\dfrac{u}{\sqrt{T^2 + u^2}}$ in our expression for index of wheel wear is our traverse factor. Where T is large with respect to u this factor will be appreciably less than unity, but as u increases the reduction in wheel-wearing action is less pronounced.

Table 2 gives values of the traverse factor for a certain machine having the work speeds previously given for draw-in cuts, and the following table (traverse) speeds: 10.02, 14.00, 17.00, 19.70, 26.90 and 32.60 ft. per min. The table shows combinations of speeds giving leads from 2.3 in. upward. As the machine was designed for a wheel $2^1/_2$ in. wide, combinations of speeds giving lesser leads of work are not given.

If we now multiply each of the traverse factors in Table 2 by the wheel-wear value for the corresponding work speed and work diameter as shown in Table 1 (draw-in cuts), we will have a table of wheel-wear values for traversed cuts. These products are given in Table 3.

By assigning certain wheels to specified ranges of wheel-wearing action, we may select the proper wheel through the use of Table 3 in the same way that we did from Table 1. Actually in the case of traversed work it is not possible to feed in the wheel to the indicated depth (as shown by the feeding mechanism) as closely for traversed work as for draw-in work, and therefore the actual cut is not so deep. This means, of course, that the "spring away" action of the work is more pronounced for traversed than for draw-in work. Careful use of steady rests is therefore very essential.

TABLE 2 TRAVERSE FACTORS

Traverse, ft. per min.	Work, r.p.m.	Lead, in.	Work Diameters 1 in.	2 in.	3 in.	4 in.
10.02	53	2.3	0.810	0.950	0.975	0.985
14.00	53	3.1	0.705	0.883	0.946	0.968
14.00	72.5	2.3	0.805	0.938	0.968	0.976
17.00	53	3.8	0.632	0.850	0.926	0.955
17.00	72.5	2.8	0.730	0.910	0.955	0.974
17.00	87	2.3	0.802	0.935	0.972	0.985
19.70	53	4.4	0.576	0.817	0.905	0.943

19.70	87	2.7	0.756	0.916	0.961	0.980
19.70	101	2.3	0.802	0.935	0.971	0.986
26.90	53	5.9	0.460	0.720	0.839	0.900
26.90	72.5	4.4	0.574	0.815	0.902	0.942
26.90	87	3.6	0.646	0.860	0.931	0.958
26.90	101	3.1	0.703	0.890	0.950	0.974
26.90	138	2.3	0.801	0.936	0.960	0.982
32.60	53	7.35	0.397	0.655	0.790	0.865
32.60	72.5	5.3	0.505	0.760	0.867	0.919
32.60	87	4.4	0.580	0.815	0.908	0.945
32.60	101	3.8	0.635	0.854	0.927	0.960
32.60	138	2.8	0.748	0.914	0.945	0.977
32.60	167	2.3	0.807	0.936	0.967	0.982

The following wheels are found to be satisfactory for our machine for traversed cuts on mild steel under the assumed conditions:

Wheel Designation		Wheel-Wear Values, Table 3
36 or 46 I	for values up to	.02500
36 or 46 J	for values from	.02500 to .04000
36 or 46 K	for values from	.04000 to .05000
36 or 46 L	for values from	.05000 to .06000
36 or 46 M	for values from	.06000

Use No. 60 grain for hard material and a grade softer; but use no wheel softer than I.

Important Note. These statements of wheel assignment are based upon assumptions of the best machine conditions and most careful operation to prevent any abuse of the wheel. Field practice will usually show harder wheels in use due to conditions which abuse the wheel. Efficiency is sacrificed where such is the case.

Production Costs

If wheel wear were the most important element of production cost, grinding efficiency might be considered on this basis without leading to the fallacy which exists today. As a matter of fact, the wheel cost is almost negligible compared with the other costs, and wheel selection should be based upon the production capacity of the wheel under the given set of grinding conditions, allowing the wheel wear to be as high as is necessary to get a free action without excessive wear (which would cause difficulty in sizing work and the need for frequent dressing). The all-important factor is the rate at which the wheel may be made to cut and still not get out of truth. This affects the grinding time, any reduction of which is of vastly more importance than an increase of wheel wear which may result from such a reduction.

TABLE 3 WHEEL-WEAR VALUES FOR TRAVERSED CUTS

32.6	167	2.3	0.04210	0.06940	0.08800	0.10230

In good practice the volume of wheel wear is approximately a tenth of the material removed (mild steel) during roughing operations. A conservative estimate of the cost of operating a modern cylindrical grinding machine (exclusive of wheel cost) is, say, five cents per minute, including labor at day-rate wages.[1] The useful content of the wheel may be assumed to be such that the wheel is actually worth seven cents per cubic inch. If production could be increased to 2 cu. in. per min. where previously we obtained $1^1/_2$ cu. in. and wheel wear jumped from 0.15 cu. in., say, to 0.25 cu. in. per min., our first cost would be: $(0.05 + 0.15 \times 0.07) \div 1.5 =$ \$0.0404 or 4.04 cents per cu. in. removed. In the second case, $(0.05 + 0.25 \times 0.07) \div 2 =$ \$0.0338, or 3.38 cents per cu. in. removed.

Now the overall production efficiency of the machine based upon all costs involved is indicated by production-cost factors proportional to the earning rate of the machine. In the first case this factor would be: (production) ÷ (cost) $= \dfrac{1.5}{0.05 + 0.15 \times 0.07} = 24.8$.

In the second case, $\dfrac{2.0}{0.05 + 0.25 \times 0.07} = 29.6$.

It evidently will pay to wear the wheel more in order to obtain the higher rate as the overall gain in the foregoing is about 19 per cent. The above assumed values are reasonable and the figures given might be considered as typical. Table 4 gives these production-cost factors, or relative earning rates based upon these costs and the grinding conditions previously assumed in Tables 1, 2 and 3, the variations being due to traverse and work-speed relations only, but with proper choice of wheels in each case. Then, for the machine which we have used as an illustration it is evident that for work of a certain size and a wheel of a certain width there is one speed combination which will utilize the machine to the greatest profit. If we are able to use wheels of the width needed to cover the lead under the best speed-relation conditions, we will obtain the best earning rate of which the machine is capable. If wide wheels are not available, we still have speed-relation conditions which will give very nearly as high a rate for the narrower wheels.

In Table 4 the production-cost factors are given for 1-in. and 4-in. diameters of work only. The factors may also be expressed as earnings per unit of time, or the relative amounts the machine would earn in equal lengths of time under the various conditions as given.

Note that, due to high traverse, a 2.3-in. wheel which earns \$3.68 in a certain length of time when grinding 1-in. work at low traverse and work speeds, will earn \$10.62 in the same length of time when using the high speeds. If the widest wheel (7.35-in. face) be used the machine will earn \$11.70 in the same length of time. The grade of wheel is suitable in each case according to the speed changes. This clearly shows that high traverse speeds cause a corresponding increase in earnings in spite of the necessary increase in work speed.

TABLE 4 PRODUCTION-COST FACTORS

Table Speed, ft. per min.	Work, r.p.m.	Lead, in.	Diameter of Work 1 in.	4 in.

26.90	72.5	4.4	9.34	29.85
26.90	87	3.6	9.00	29.00
26.90	101	3.1	9.03	29.10
26.90	138	2.3	9.00	29.15
32.60	53	7.35	11.70	35.70
32.60	72.5	5.3	11.30	34.60
32.60	87	4.4	11.00	33.60
32.60	101	3.8	10.90	33.40
32.60	138	2.8	10.80	33.30
32.60	167	2.3	10.62	32.90

Considering the cost of wheels 7.35 in. wide as compared to wheels 2.3 in. wide, and the relative power required to drive the two wheels, it is very evident that the use of a harder wheel 2.3 in. wide would offset the difference in wearing action without greatly reducing production and that the production of the 7.35-in. wheel is matched by the production of the 2.3-in. wheel using highest traverse and highest work speed.

[1] The figure of 5 cents a minute as time cost of operation is based upon labor at 75 cents an hour and an hourly burden of \$2.25 an hour (power, investment, rent, heat, light, etc.).

The most striking conclusion from the above is the fact that in order to use a narrow wheel and get great production the high work speed does not cause excessive wheel wear *due to the relief* on the wheel brought about by the *high traverse speed*. This traverse speed is also necessary to allow the rapid exposure of fresh work surface to the cutting face, making for a highly economical combination.

The foregoing should demonstrate clearly what this new development in the science of grinding may mean to the art as practiced throughout our production shops.

Actual grinding tests upon a machine having the high-traverse feature, and making use of the speeds shown in the table, have conclusively proven the deductions indicated by the mathematical calculations. On mild machine steel (0.15 per cent carbon) over diameters ranging from $^3/_4$ in. to 4 in., production rates as high as 2.00 cu. in. per min. have been easily attained, grinding to limits of 0.0010 in., removing 0.060 in. from the diameter over lengths of from 36 to 72 in.

When machine conditions, truth and balance of wheel, and proper use of steady rests and grinding compound are intelligently and skilfully handled, wheels of 36 and 46 grain size, and grades I to L (Norton system of grading) have been used in these roughing operations. Especially where the feeding is carefully regulated so as *never* to *crowd* the *radial depth* of cut to more than the possible depth of grain penetration (say, not to exceed 0.0015 in. on the diameter) per traverse, it has been found that the wheel face remained sufficiently true to leave a commercial finish of fair degree absolutely free from chatter marks, feed lines or any other imperfections of real or imaginary consequence.

Owing to the fact that in the above the highest work and traverse speeds were used in every case, the grade (hardness) of wheel was increased as the diameter of the work increased. This is in accordance with our formula for index of wheel wear. Instead of considering the work speed and work radius independently, they were in this case tied together by the fact that a constant work r.p.m. was used. The expression for this is as follows:

$$\text{Work speed } u = \frac{2\pi r N}{12} \quad \ldots\ldots\ldots\ldots\ldots\ldots [5]$$

where r = work radius (inches) and N = r.p.m. Substituting [5] in [4],

$$WW_1 = \frac{0.275\mu}{V^2}\left(\frac{N^2}{\sqrt{T^2 + 0.275r^2N^2}}\right)\sqrt{2fr^3} \quad \ldots\ldots\ldots [6]$$

Now if V, N, T and f are made constant, WW_1 must vary as the value r appears in the formula, the greatest effect being the $\sqrt{r^3}$ factor and we would expect therefore to use harder wheels as r increases.

Conclusions

The conclusions to be drawn from the foregoing are definite and indicate positively how to arrive at the solution of precision grinding problems, provided one has an intelligent knowledge of abrasive wheels and the usual materials ground.

Greatest grinding efficiency is obtained by the use of the *softest wheels* suited to the nature of the material ground. This efficiency is dependent upon the control of the dimension and speed relations between the wheel and the work so that the individual chip may have the minimum depth for a given volume determined by the maximum allowable radial depth of cut. This means long arc of contact, low work speeds and maximum feeds. With these conditions established, *increase of traverse speed increases production without increase of wheel-wearing action.* Machine conditions must be such as to maintain as accurately as it is reasonably possible the speed and dimensional relations of the wheel and the work.

There is an enormous field for the industrial engineer in obtaining better production at less cost in grinding operations. There is a definite science involved, there is no mystery about it. The proper appreciation of the laws of grinding by machine designers and operators is rapidly increasing and we may expect a constant improvement in the art as a consequence.

The Specific Mechanical Purposes for Which Cloths Are Used and an Enumeration of Their Applications in the Most Important Industries

By JAMES W. COX, JR.,[1] NEW YORK, N. Y.

Cloths for mechanical uses are made from practically all the well-known fibers, cotton predominating, with wool, asbestos, silk and linen following in about the order named. Occasionally other fibers are used in cloth for special purposes. Cloth is used for mechanical purposes where it only will function or as a substitute for leather, metal banding, metal cloth, rawhide, sheet metal, wire or wire screen. Cost is usually the principal consideration for substituting cloth for the above materials; also it has been found in many instances that a fabric did the work in a better manner than the original substances, flexibility being a large factor in its adoption.

These cloths can be classified as to specific uses and to different industrial groups. It is impossible in one paper to give every specific use of mechanical cloths. The following tabulation, however, roughly covers their most common uses:

Absorption	Containers	Inking	Pressing
Aprons	Cushion devices	Insulating	Screens
Backings	Curtaining	Jacketing	Sieves
Bagging	Distributors	Laminated materials	Slings
Belts	Drying	Leaders (machine)	Steaming
Binders	Facings	Linings	Straps
Buffers	Fabric bases	Marking	Tapes
Bumpers	Filters	Moistening	Tracing
Cabling	Flame protectors	Packing	Tubing
Carriers	Formers	Paddings	Washers
Cleaners	Gaskets	Partitioning	Webbing
Conveyors	Grips	Patches (repair)	Wicks
Covers	Hose	Polishing	Windings

Practically every industry uses cloth mechanically in some way, those listed below being the largest and perhaps the most prominent consumers:

Aircraft	Conveyor	Mining	Printing
Army	Electrical	Musical instruments	Pumping
Automobile	Engraving	Office machinery	Railroads
Baking	Farm machinery	Oil	Rubber
Beverage	Flour	Packing (mechanical)	Shipbuilding
Candy	Gas manufacture	Paint	Shoe machinery
Canning	Household machinery	Paper	Textile
Chemical	Laundry machinery	Powder	

Specific Uses

Absorptives. Coarse plain-woven jute and cotton cloth are used for this purpose. In either case the material is impregnated chemically so that when put in a machine, room or mine it will absorb gases of various kinds, moisture, etc. Cloth for absorption purposes is generally known as "brattice cloth." Jute was almost universally used until the price mounted; now low grades of cotton and cotton waste are used to a large extent as a substitute.

Belting. Woven belts are made for practically every purpose a leather belt is used for, including conveyors and machine aprons. Woven belting is being used plain, or impregnated with various substances such as tar, rubber and materials of this type. It has the advantages of being more nearly heat-, gas-, moisture- and water-proof and is usually cheaper. Belts of this type are made wholly of cotton, or if excessive strength is required the warp is of camel's hair. In general they are a two- to eight-ply plain fabric made like a webbing and resembling before treatment a heavy, thick, narrow duck.

Belts of canvas or light duck in two-ply and up are also made by stitching the length of the belt every half-inch or so apart. Then this is treated or impregnated in the same way as the solid-woven fabric.

Bindings and Check Straps. Heavy cotton webbing is used on various types of machines for lifting mechanisms. It is used in loop form on automobiles to prevent the too rapid recoil of the springs, also in special patented devices to achieve the same purpose. It is used for check straps on machines, train signals, and in street and railroad cars. Impregnated, light cotton tape is used for making various pipe connections and in electrical wire splices.

Conveying. Cotton duck, from light army to heavy numbered, is used extensively in conveying machinery of all kinds. Camel's-hair, plain cotton and stitched canvas belting is also used either treated or plain, according to the conditions under which the conveyor is run. The widths and weights vary from a cotton webbing for conveying small machine parts, to a heavy double- or triple-width belt for a box, barrel, coal or iron conveyor, etc. In two industries, candy making, and photographic-film making, cotton oilcloth is used on account of its smoothness and ease of cleansing.

Filtering. The filtering or straining of gases, air and liquids is considered under this head, the sifting of solids being taken up under "Sieves." In some cases when the filtration is slow and the pressure great the process is known as "pressing," but the action is identically the same, taking out substances that are not desired.

In the manufacture of some commercial gases a fine plain-woven linen, cotton or woolen cloth is used to take out solid particles of matter which are occasionally present. Fine asbestos cloth is also used when a detrimental chemical action would take place on cotton, flax, or wool. Medium asbestos and cotton cloths are used as smoke screens where cinders are an objection. In a few types of air-filtration installations a coarse cotton sheeting is used to take out the heaviest dust particles as the air enters.

As strainers on the ends of flumes in power-house work coarse open-mesh cotton or woolen cloths are used. They are usually called "flume bags" and are used secondarily to wire mesh which prevents the large pieces of substances getting in the pipes. Cotton strainer cloths are used sometimes in the pipes leading to water filters. They are used in canning establishments for the straining of fruit and vegetable juices and somewhat in factories making soups, sauces, relishes, etc. In cider mills a heavier, more open, and thicker cotton cloth is used for the extraction of the apple juice. It is generally a two- to five-ply yarn, loosely woven fabric, resembling a tire fabric in many ways with the exception of the tightness of the weave. This type of cloth is also used in the preliminary straining of other fruit juices.

The filtering of liquid chemicals is done by many kinds of woolen, cotton, linen and asbestos cloth. Some paint makers use a cotton filter cloth also in their manufacturing processes.

In the oil industry cotton filter cloths are used extensively. Crude oil, kerosene, gasoline, benzine, naphtha, linseed oil, cottonseed oil, in fact all kinds of oil, are generally filtered or "pressed" in the making. The cloths range from thin sheeting to heavy duck or multiple-ply hair cloth. When the oil is quite fluid, cotton sheetings and twills are used, and as the viscosity increases the heaviness and thickness of the filtering cloth increase. So next, heavier, thick twills are used, more on the order of a denim, then light duck, army duck and finally the very thick and many-ply cloths where the liquid is forced through by great pressure. These fabrics are of cotton, horse and other hairs. For the heaviest work where they have tremendous strain and pressure, a camel's-hair three- or four-ply cloth is used. These latter types are called "press cloths." In general they are stretched between flanges in a pipe and the oil or liquid forced or "pressed" through them by great pressure, necessitating great strength.

In the case of garbage or sewerage reduction the cloths used are of ply yarns, very open and plain weave. Asbestos cloth is used here to great advantage as it can be cleansed easily by subjecting to fire.

[1] Textile Engineer, 320 Broadway. Mem.Am.Soc.M.E.

Abstract of a paper presented at the Annual Meeting, New York, December 1920, of The American Society of Mechanical Engineers. All papers are subject to revision.

Laminated Cloth. One of the principal uses of laminated cloth is for polishing. Practically always cotton cloth is used, osnaburgs, sheetings and in some cases light duck. Woolen cloth is used in glass polishing to some extent. Laminated cotton-cloth buffers are built up to any desired thickness, stitched, die-cut in circular form and occasionally stitched again spirally. A center of metal or wood is inserted and the polishing wheel is ready for service. This type of polishing wheel is used for polishing leathers, artificial leathers, woods, metals and various kinds of composition materials. It is sometimes used in hat cleaning.

Laminated cotton sheeting impregnated with composition materials of various kinds has been used also in certain types of universal joints. In the textile industry laminated numbered cotton duck stitched, riveted, or both, is used to some extent on looms in the form of lug straps, check straps and pickers. Fine sheeting and light duck laminated and impregnated with composition materials are used for the making of gears. The blank is built up and the gears are cut the same as if of iron, steel or rawhide. Laminated cotton sheeting alternated with a cheap, light woolen flannel is used at times for making pads on which great pressure is brought and where pressed felt would spread and cause an uneven surface.

Laminated cloths are used for packing as noted under that heading.

Packing. Cotton and asbestos cloths, plain and laminated, are used extensively for mechanical packing, in gaskets and in washers of various kinds. The cotton cloth is generally impregnated with composition materials of various kinds and cut in the desired shapes necessary. Asbestos cloth is used both plain and impregnated in the same manner as cotton cloth. It is used for the most part in places where there is great heat. It has this advantage over cotton-cloth packing, but under a tension the latter is generally better. Impregnated jute cloth is also used at times where a cheap packing is desired and no particular strain or heat is present.

A large amount of cloth packing is consumed by prime movers of various kinds: steam engines and turbines; and gas, kerosene, gasoline, and various kinds of oil engines. It is used generally about any power plant. Pipe joints use impregnated cloth packing of all kinds and the consumption of the material in this way is very large. Light army duck and sometimes a light flat duck are used as the outside covering of asbestos and magnesia pipe coverings.

Pads. Under this heading a closely woven cotton sheeting or some times a light twill is used as the covering on inking pads in the printing and engraving industry, particularly on flat-press work. As heretofore described, occasionally a laminated pad made of cotton sheeting and woolen flannel is used on work where there is much pressure against the pad.

Flat ironing machines as used in laundries and homes have a woolen-flannel backing covered with a thick sheeting or light duck as a press pad. This same type of machine somewhat modified is used in tailoring establishments where pressing is done in large quantities.

Polishing. Cloth is extensively used in polishing all kinds of surfaces. Cotton cloths of various types are laminated, sewed or riveted and then cut in disk form for polishing and buffing. They are used for polishing leather, wood, compositions and metals of various kinds, in the shoe industry and automatic shoe-polishing machines. The jewelry and electroplating trades use this type of polisher to some extent. In some instances cotton webbing is used when a heavy pressure has to be brought to bear.

In the making of lenses and various articles of glass, polishing is done by heavily felted woolen cloths, which cover the polishing wheels. These cloths vary from a thin billiard cloth to a thick heavy melton. Woolen cloths are sometimes used in the finishing of hats.

Pumping. Flexible cotton hose, plain or treated, is used very generally in pump connections for gases, air and liquids, especially in industries where a portable pump is necessary. The number of uses is legion and the following are fair examples of its very wide application:

a For gas work, in the handling of oxygen, nitrogen and most commercial gases

b For air use, in the portable vacuum-cleaning outfits on wagons and automobiles, on house, factory, and office cleaners, the connections on compressed-air drills of all kinds, connections on sand-blast cleaning outfits, and on outfits for pumping air to divers

c For combination air and liquid pumps, in the connections for various types of atomizers, spraying devices, etc.

d For liquids, in the connections on water pumps of all kinds; e.g., gasoline motors, fire engines, mine pumps, etc. On spray-painting connections and pumps of that type

e For liquids mixed with solids, in the connections for contractor's pumps, dredge pumps, bilge and boat pumps of different kinds, filtration and sewerage pumps, etc.

Sieves. Cloths of various kinds are used as sieves. The finest is known as silk bolting cloth and is a gauze-type fabric varying from about 20 meshes to the inch up to 200 for the very finest. This is made up to about forty inches in width and is used for sifting flour and any substance which has to be used in very fine powdered form as chalks, paint bases, chemicals, etc. Sieve cloths are made also of linen and cotton in various meshes and weights for not such fine work and where the silk cloth has not the required strength. The weave is practically always plain and the yarns fine.

Treated Cloth. Cotton cloth in the form of sheeting, duck, belting, webbing and tape is used extensively as backing for different types of impregnated fabrics, cloth made of other fibers being rarely used. The treated fabrics may be divided in the general classes of rubberized goods, oilcloths, artificial leathers, insulating materials, impregnated laminated cloths, and semi-transparent sheeting. They can best be described in this order.

Rubber-treated cloth is perhaps most used. Tires consume a large amount of sheeting and a special fabric. Belting and webbing are used for conveyors, belts, and straps. Sheeting and duck, plain and laminated, are used for packing gaskets and washers. Sheeting and duck are used for printers' blankets, bolster aprons on machines for removing hair from hides, paper machines, electric separators and various other purposes. Tubular fabrics are used for hose, tubing and sleeve work.

Sheeting and duck made into oilcloth are used in various ways. As a conveyor apron on office duplicating machines, as aprons on paper-mill machinery, as backing on the drums used on a tapestry carpet loom which prints its own filling, and as a conveyor on one of the machines used in fur-hat making. Oilcloth as belting or as webbing is used as a conveyor under certain circumstances where a smooth surface is desired. Its use in photographic-film manufacture and candy making are good examples of this. Oilcloth can in general be used to a great extent in places where a rubber-treated cloth is used.

Artificial leathers are a more recent development and have just started to prove their practicability in industry. So far their use for mechanical purposes is practically nil.

Treated cloths for insulation are described under the heading Electrical, and laminated treated cloths are discussed under the headings Polishing and Laminated Cloth.

Semi-transparent treated cloths are used for shades, light filters, and in tracing cloth for mechanical drawings. The cloth used varies from a $4^1/_2$-yd. cotton sheeting for shades down to a very fine linen for tracing cloth.

Wicks. Cotton webbing and in a few cases soft, thick flat duck are used on machinery for purposes of a wick to convey various kinds of liquids to a certain point. Soft webbing is used in heater appliances for the conveyance of gasoline, kerosene, and various oils to be burned. It is also used in moistening, oiling, gumming and inking machines of various types for conveying the liquid slowly to a certain point or surface.

Industrial Groups

Aircraft. This heading is readily divided into three classes: aeroplanes, balloons and dirigibles. On aeroplanes cloth is used in all ways common to the gasoline motor, as described under the heading Automobile. The wings use cloths of silk, linen or cotton

of rubber covered with cotton cloth to prevent incendiary bullets from igniting the gasoline. The straps used on the seats are often of cotton webbing in place of leather. The grip of the steering lever is often cloth-covered. Balloons use silk linen and cotton cloth for the bags. Dirigibles use the same type of cloths for the bags and body coverings.

Army. The cartridge carriers for automatic rifles and machine guns are metal or a combination of cotton webbing and canvas. The best types of the latter are woven as a part double cloth separated canvas and part webbing. In this manner is woven on one machine the belt in its entirety with pockets and flat spots as desired. Other carriers are made by stitching two webs or two layers of canvas. The slings and strappings for almost all guns are now cotton webbing in various widths and weights. The straps on gun carriages, wagons, tanks, tractors, etc., are practically all cotton web. Silk cloth is used for powder bags. It is generally a plain-weave, roughly made, silken fabric of coarse yarns spun of silk waste.

Automobile. The automobile is a very large user of textile products for mechanical purposes. On the motor, treated-cotton or asbestos-cloth packing, gaskets and washers are used. The fan belt is often either a plain cotton webbing, treated webbing, or an endless belt made by cutting cotton cloth on the bias, building up two to four layers of same and then rubberizing. In this way an endless belt is made which has good wearing qualities. Asbestos wrapping is often used around the exhaust manifold. Practically all water-circulating systems, whether pump or thermostatic, use a rubber-impregnated cotton hose.

Asbestos cloth has been used as a facing for clutches. Asbestos webbing is used for brake linings, plain, or more often with a wire warp and asbestos filling. Plain, thick cotton webbing is also used as brake linings on the cheaper cars. Foot-pedal grips are usually canvas-backed, rubber-treated cloth. Door straps are of heavy cotton webbing, plain, rubberized, or made into artificial leather.

On a certain type of cheap car a thick, narrow cotton webbing is used in the transmission. Cotton webbing in various widths and weights is used for plain check straps on the axles and for special devices for preventing too rapid recoil of the springs after going over a rough spot in the road.

In the electrical system impregnated silk or cotton cloth and cotton and asbestos tubing are found on the generator, motor, magneto, transformer coil, distributor and wires. A treated cotton sheeting is universally used for covers on the steering connections, magneto distributor, springs, etc. In the making of wheels, particularly a certain type of truck wheel, cotton canvas or duck is used. It is placed as a cushion and fitting device between the spokes and the felloe.

The automobile tire consumes a tremendous amount of cotton cloth annually. Plain tire fabric, cord fabric, breaker-strip cloth, and lining are so well known as to need no mention in this paper. Blow-out patches of a rubberized cotton fabric and tire-tread covers, used mostly in Europe, are usually a cotton-canvas backing reinforced in various ways. In the manufacture of tires a cotton sheeting is used in the mold.

Bakeries. The majority of cloth consumed is heavy duck, principally "00" weight. It is used as conveyor aprons in the ovens, mixers, conveyors and wrappers in the most modern up-to-date bakeries. Some webbing is used in the same way. Heavy sheets of asbestos cloth act as heat protectors in the ovens. When flour or other ingredients in the making of cake have to be finely sifted, a very fine cotton sheeting or silk bolting cloth is used.

Candy Factories. The same kind of cloths are used in this work as are used in bakeries, with the exception that some of the conveyor belting is of oilcloth, in order to have a smooth surface easily cleansed.

Chemical Work. Cloths of silk, cotton, linen, wool and asbestos are used in different ways in this industry. They are used principally for sieves and filters. Most of them are of fine, hard-twisted yarns, plain woven goods of various degrees of closeness, though twill weaves and double-cloth fabrics are occasionally

Electrical. In this industry cloth is used primarily for insulation work and generally impregnated with a composition material of some kind which is a non-conductor of electricity. For fine-wire insulation and very fine machine work silk tapes and cloth are used. As the sizes increase in each case the tendency is to use cotton tapes or sheeting. Abroad, linen tapes and sheeting are used somewhat, but their use in this country is not general on account of the cost and cotton can be substituted. On cable work cotton and asbestos tubing are also used. Asbestos webbing is used in the making of large generators.

In the telephone industry the uses of cloth are similar to those already mentioned; one particular webbing, however, is of interest as it is not believed such a web is used in any way comparable to it. A $1^1/_2$-in. web of wire warp of about forty ends is made with a heavy silk filling to insulate the warp. Diagonally at short intervals across the filling there are open spaces left, leaving the warp bare so that connections can be made. This web is used in switchboard work on board connections.

Engraving. Fine cotton sheeting is used in this industry to cover the inking pads on certain types of engraving machinery. The backing of the engraving press itself is usually a woolen cloth. It is a very fine, closely woven, and closely sheared woolen, very much on the order of a billiard cloth.

Farm Machinery. Army and numbered duck, cotton webbing and belting, packing cloths and hose, plain or treated, are used in farm machinery in varying amounts. They are used on tractors, tractor plows, ditch diggers, harvesters, threshing machines and pump connections of all kinds.

Household Machinery. Vacuum cleaners use treated cloth, usually cotton, as air and refuse bags and in certain types narrow cotton webbing is used as a drive belt. The hose connections are rubberized cotton hose. Some washing machines are partly cotton-cloth-lined to prevent splinters getting into the clothes. Narrow cotton webbing is used for driving belts. In certain kinds of carpet sweepers a rubberized narrow webbing is used as bands or rims to drive the brush rolls. Some mechanical mops use loosely bound laminated cotton cloth, generally a low-grade sheeting or osnaburg. On mechanical ironers cloths are used in the same way as in the laundry industry.

Laundry Machinery. Cotton or woolen cloth is used quite extensively on this machinery. The principal place, perhaps, is on the rolls of a cylinder ironing machine. These rolls are of metal. First is wound a cotton sheeting; next, many layers of what is termed laundry flannel until a good cushion backing is formed. This flannel is a heavy, straight or broken twill, all-woolen blanket. It is of a coarse wool and heavily napped to get the maximum cushion effect. On top of this flannel is wound a covering of light duck, usually about a No. 12.

On flat press ironers, resembling an old ironing board, two or three layers of the woolen flannel are used, covered by a couple of layers of cotton sheeting. On the starching machines a very open-mesh cotton cloth is used as a conveyor apron. It is made of about eight-three's yarn counting about eight to twelve warp threads and picks to the inch. On other machinery where conveyor aprons are needed, duck is used but heavier than on the ironing machine. In general the duck is a No. 4, 5, or 6. Woolen strainer aprons or cotton sheets are used to some extent to prevent the cloths from touching the inside of the extractors. These are any old cloths available. In the washing machines or kiers where family "wet wash" is cleansed, open-mesh bags are used to hold the cloths, in order to keep each lot separate as they turn over in the machine.

Musical Industry. Both cotton and woolen cloths are used in the manufacture of pianos, inasmuch as felt will not cover every purpose. These are used in the actions and in the keyboards. In piano players cotton webbing also is used for belts and treated cotton cloth in the bellows. In organs cotton strapping is used, treated cotton cloth for bellows and, in case of mechanically driven organs, cotton belting for drive belts. Motor-driven music boxes use webbing for belts.

On a few of the best-made phonographs a woolen cloth is placed

on top of the metal plate holding the record while being played. This replaces pressed felt. The cloth used for this is very much like a thick, coarse billiard cloth. Heavy cotton sheeting or light twills, drills or flannel are used in the manufacture of the record itself.

Office Machinery. The equipment of most business offices includes typewriters and adding and bookkeeping machines. These all require an inked ribbon for their operation and here a fine textile product is used. It is a cotton cloth made of very fine combed yarns, plain weave and generally from 80 to 100 counts each way. It is split lengthwise, gummed at the edges, inked and wound on small spools ready for use. On the stenotype machines there are also ribbons of this character.

On some adding machines, bookkeeping machines and dictaphones there are belts for driving them by electric motors and these are in most cases fine, narrow cotton webbing. Cotton sheeting and flannel are used in the manufacture of the record for the dictaphone. On duplicator machines of various types the conveyor aprons used is a cotton-back oilcloth.

Paper Industry. This industry is one of the largest users of textile products, and is entirely dependent on them, as contrasted to other industries where the textile product may be only an aid in producing results. The fabrics used are made of wool or cotton and are called woolen or cotton "felts," as the case may be. A pressed felt was originally used for the purpose and the name has remained although the product has changed to a woven piece of goods. Woolen "jackets" are also used. These are tubular woven cloths, for shrinking on steel rolls hereinafter described.

The first machine in the paper industry on which a fabric is used is the pulp machine. A thick, open-mesh, plain-weave, heavy, endless woolen fabric takes the stock from a tub and deposits it in layer form on a cylinder from which it is afterward cut in the form of sheets.

On paper-making machines, as the paper stock comes from a revolving wire screen, it is deposited on an endless woven "felt" and by this "felt" is carried through iron press rolls on which is shrunk the heavy woolen "jacket." In this manner the water is squeezed through the "felt" and the thin film of stock or partly formed paper is left on the top of the moving cloth. It is carried through numerous pairs of jacketed rolls and by thicker and finer "felts" and finally is formed paper.

The jackets are tubular two- to five-ply woolen cloths, very closely woven, and felted very hard. They are fulled down to a size less than the roll circumference, and sheared closely; then wet, stretched and placed on the roll. When dry they are so tight they are practically a part of the roll and form an excellent cushion.

The woolen felts mentioned above on which the paper is formed vary from a light, thin, open, well-napped blanket to a close, soft, thick cloth much on the order of a very heavy overcoating. They vary in degrees of openness, thickness, nap, etc., according to the conditions under which run. Double-cloth woolen "felts" having the back cloth a flat, smooth, hard-felted surface and the face cloth of hard yarns, are used as "marking felts," to make a special design on the paper after it has left the regular forming felt. "Carrier felts" of coarse, heavy woolen yarns, heavily fulled, are also used at times to convey the paper from one set of rolls to another.

With the paper formed but wet, it is delivered to an endless cotton "felt," which carries it around many steamed-heated cylinders until dry. The cotton drier "felt" is a very thick heavy duck. It is usually a three- to eight-ply cloth, each ply averaging as heavy as No. 4 duck. The weight, thickness and yarns used depends on the conditions under which it is run.

Heavy cotton webbing or doubled duck, impregnated with rubber, is used as a guard on each side of the wire screen which delivers the stock to the "felt." This cotton rubber-covered strip is called "deckle strap." Apron conveyors used between the wire screen and first woolen "felt" are made from cotton cloth or duck either rubberized or made into oilcloth.

Printing. In the printing of textiles, whether silks, linens, cottons, woolens or carpets, cloths are used in three ways. The cylinder which operates against the printing roll is first wound with a linen or linen and woolen lapping. The linen lapping gives a backing to the roll and is used on account of its strength. It is a plain-weave, tightly woven fabric. When the linen and woolen lapping is used, the warp is linen and the filling wool. This gives the requisite strength and more cushion. Stretched around this cylinder to another roll, is an endless belt, a sort of woolen jacket, which being next to the cylinder lapping gives the cloth being printed a cushion to work against. This woolen belt is a two- or three-ply, very close, heavily felted cloth, woven endless usually to get a smooth no-lap effect. Under certain conditions of printing a partially cotton or a rubberized cotton cloth is used in place of a woolen. In printing filling yarn on a tapestry carpet loom of a certain type a cotton-backed oilcloth is used on the drum. The third place where a cloth is used in this kind of printing is for a leader to carry the cloth to be printed into the machine. It is called the "backgrey" and is a heavy, closely woven cotton sheeting. No matter how many cylinders or printing rolls are used the principle is practically the same.

Narrow fabrics such as ribbons, tapes, fancy straps, suspender and other webbing are printed in practically the same manner. This same method is also used in printing wallpaper. In rotary printing presses for printing newspapers, magazines, and other big work the principle is the same, the difference being in the method of application. This is likewise so in rotary engraving work, the cloths in general being the same.

When flat printing or engraving is done, however, a cotton-sheeting-covered pad, a heavily felted light woolen, or a laminated cotton cloth and flannel backing are used. When inking is done by pad the covering is cotton sheeting.

Railroad Work. Cotton hose, usually treated, is employed for practically all airbrake connections on cars of all types. Also in steam and water connections for cars, roundhouses, stations and shops. Some parts of signaling systems use cotton webbing of different widths. On the individual electric car-lighting systems the generator is often driven by a rubberized cotton belt. Webbing in general is used as slings, straps, etc., in railroad-shop work. In steam packing for locomotives cloth is used in general as on a stationary engine. On electric locomotives insulating cloth is used as described under the head of electrical work.

Shipbuilding. The building of ships consumes much cloth in a mechanical way, not to mention the tons of duck used non-mechanically. It is used as cotton and asbestos packing in engines, turbines and pumps, pipes and pipe covering. Flexible cotton hose is used with certain types of ship pumps and it is also used for dredging sleeves for certain types of dredge pumps. Heavy cotton webbing is being gradually introduced to take the place of ropes where a flat surface is preferable to a round one; this is particularly advantageous for ship cranes in loading and unloading light cargo.

Shoe Industry. Wide cotton numbered duck is used on the shoe machines which form the box toes and heels of ordinary shoes. It is used as a forming agent for the parts of the shoe mentioned. Light 12 to 16-oz. duck is also used as backers or formers on other machines. Laminated cotton cloth in the form of buffer wheels is used for polishing.

Textiles. In the manufacture of textiles, cotton, woolen, jute camel's-hair, linen and asbestos cloths are used. These are so familiar to every engineer in the textile industry that no descriptions of them are necessary; therefore a tabulation only is given in order to have them in proper form. Cotton is used most extensively, approximately 80 per cent of the poundage being of that fiber:

a Belting. (Cotton or camel's hair, plain or treated):
- Main drives
- Machine drives
- Within machine drives
- Narrow conveyors.

b Card Clothing. (Linen, cotton and wool):
- Backing for various types of card clothing

c Clearer, Slasher and Roller Cloths. (Wool and cotton):
- Cotton, woolen and worsted work

d Cotton Duck:

1 Aprons for:

Automatic feeds	Driers	Openers
Blamire feeds	Dusters	Pickers
Camel's-back feeds	Fiber softeners	Scouring machines
Carbonizers	Fur depositors	Take-up rolls
Conveyors	Gill boxes	
Crosser formers	Loom beams

Discussion on Motor-Truck Transportation, Government Operation of Inland Waterways, and the Proposed Plan for Handling New York City's Freight and Passenger Traffic

OF THE six papers presented at the sessions on Transportation, held in connection with the 1920 Annual Meeting of The American Society of Mechanical Engineers, three have already been published in the January issue of MECHANICAL ENGINEERING, namely, Railroad Transportation, by Daniel E. Willard; Feeders for Railroads, by Charles A. Morse; and Railway Terminals and Terminal Yards, by Col. William Barclay Parsons. Other papers presented were by Gen. Frank T. Hines on the Government and Inland Waterways, by Francis W. Davis on Motor-Truck Transportation, and by Gustav Lindenthal on the Transportation and Terminal Problems of New York as Affected by the Hudson River. Summaries of these latter are given in what follows, together with an abstract of the written discussion on Transportation offered at the meeting by J. R. Bibbins.

MOTOR-TRUCK TRANSPORTATION

BY FRANCIS W. DAVIS,[1] BUFFALO, N. Y.

IN THE short period of twenty years, motor highway transportation, in capital invested and diversified fields of application, has reached the point where it is warranted in seeking counsel with its elder brothers in transportation Except for certain specialized services the motor truck will never replace waterway and railway transportation, nor be related to them in other than a supplemental capacity.

The problem has three main aspects: (1) The field of truck transportation; (2) the present status of truck transportation; and (3) the improvement of truck transportation.

THE FIELD OF TRUCK TRANSPORTATION

In cheapness, capacity and low operating costs, waterways, where available, present the most economical form of transportation, especially for bulk material. There is and can be but little competition between waterways and the motor truck.

It is in the "short haul" and at terminal points that the railways are at greatest disadvantage, both as to service rendered and to their own earnings; and it is here that motor transportation comes as a help and releases cars for the long hauls where they are most efficient.

Where railroads and motor trucks do compete, as in the short haul, the problem is to determine which is best suited to discharge the service, where the advantages shift from one to the other, and then let each specialize in the field where it is the more efficient and economic.

The ratio of labor required to tonnage handled precludes the competition of motor trucks with the railway on the long haul.

A table given by the author shows the relative cost of shipping by rail and truck for various lengths of haul.

There is another field of service in which the motor truck is not in competition with other forms of transportation, the so-called "combination service." The truck engine, used primarily for transportation, is available for auxiliary purposes and increasing use is being made of it for loading and unloading operations, the driving of winches, cranes, pumps, etc., and for miscellaneous power requirements.

PRESENT STATUS OF TRUCK TRANSPORTATION

There are approximately 800,000 trucks in operation. If each of these averages five tons per day for 300 working days per year the total tons moved by truck would be about 1,200,000,000. This is of course only an approximate estimate. There is great need for accurate statistics on motor transportation similar to those available for the railways.

Truck operating costs vary so with conditions that general averages are almost useless as a guide for specific cases.

[1] Engineer, Pierce-Arrow Motor Car Company.

The question of possible increase in size of motor trucks is an economic one. There is no mechanical limitation preventing a considerable increase in carrying capacity, but if the size increases much beyond the present maximum of 5 to 6 tons capacity the vehicle becomes unmanageable, and the inability always to operate at capacity loads offsets the advantages of large-size units. The weight, too, would exceed the carrying capacity of many of present highways and bridges.

The development of the motor truck is intimately related to the rubber tire.

IMPROVEMENT OF TRUCK TRANSPORTATION

In 1918, J. E. Maloney, of the State Highway Department of Colorado, in an investigation of the 131 roads which constitute the state highway system of 3827 miles, gave the following conclusions:

> Taking the traffic for the 3827.6 miles, estimated in the tables published in December as 162,926,098 ton-miles, and applying the average cost, as given in the operating costs, of 10.8 cents per ton-mile, will make $17,595,917 per year as the operating cost for the traffic alone.
>
> A saving of but one cent per ton-mile on this traffic would equal $1,629,261 annually, which sum capitalized at 5 per cent would warrant the expenditure of $32,585,200 in the improvements necessary to effect this annual saving.
>
> From a gravel to a paved road there would be an average saving of 1.1 cents per ton-mile, so that an annual traffic of 95,000 or more ton-miles per mile of road would justify an expenditure of $21,000 per mile for the improvement.

If such savings are obtainable in a sparsely settled state, such as Colorado, proportionately greater savings should follow road improvement in the more densely settled sections where traffic is much heavier.

Proper surfacing and foundations are the greatest need. Grades are of very little importance if these are right. It will be necessary, however, to have bridges of ample capacity to take maximum loads.

Both motor transportation and the highways should be protected by reasonable legislation.

In conclusion, railway transportation should and will hold its place for long hauls and for carload shipments where there is direct railway connection to the factory or warehouse of the shipper. Motor transportation will relieve the railroads of the expensive short haul, serve them at terminals, and widen the zone tributary to the railroads thoughout their entire length. It will supplement the street railways and will spread into a wide field where the engine power can be utilized for auxiliary purposes. With the steady improvement of devices for shortening the loading and unloading time there will be a reduction in the use of horses for heavy freight haulage.

The ecônomic limit of the size of motor trucks will probably remain about as at present, although the use of trailers will increase the tons hauled per movement. The use of motor trucks will increase with the general improvement of the highways. The motor industry will welcome sound and uniform legislation, and aid in securing it.

THE GOVERNMENT AND INLAND WATERWAYS

BY FRANK T. HINES,[1] WASHINGTON, D. C.

A REVIEW of the experience of the Government in the operation of inland-transportation-service boats during and following the late war discloses that prior to the creation of the Council of National Defense but one comprehensive survey of the possibilities of inland water routes had been undertaken, namely, the Inland Waterways Commission, instituted by President Roosevelt in 1910.

The investigations of this body resulted in the accumulation

[1] Vice-President, Baltic Steamship Corporation of America.

of a wealth of data covering the status and traffic possibilities of our navigable and potential water routes, and its findings were submitted to the readers of public documents in some eight hundred pages.

From 1910 to 1916 but little was done by the Government for the improvement of waterway transportation aside from the routine river and harbor work of the Corps of Engineers of the Army. In the latter year came the forerunner of the present permanent Waterway Bureau, the Committee on Inland Waterways of the Council of National Defense.

Under the pressure of wartime conditions of 1917 this committee presented reports which were instrumental in later developing a definite governmental policy toward waterway transportation.

With the coming of the United States Railroad Administration and the actual coördination under Government control of all public transportation agencies, the waterway problem was forced still further toward a permanent solution. With the previously active competition between railroads and waterways temporarily suspended, there was presented an unprecedented opportunity for testing out on the basis of strict utility the relative merits of water-borne transportation.

An examination of the several phases affecting traffic on water routes revealed conditions eloquent of the demise of waterway transportation. On the Mississippi, upon which millions in federal appropriations had been spent, scarcely a craft was stirring. On the Warrior River, whose principal utility lies in its situation as an economical outlet for the coal, ore and lumber of central Alabama, a similar situation was met. On the New York State Barge Canal an equally discouraginge ondition existed, though due to the process of transference of traffic from the old route of the Erie Canal.

Early in the spring of 1918 the Director General of Railroads instructed that plans be prepared to make a maximum use of these waterways for the relief of wartime freight congestion. Whether physical operations on these routes should be maintained directly by the Government, as were other common carriers at that time, or whether better results could be secured by encouraging and assisting private enterprise, were questions left to the committee for solution.

After several weeks of intense study the committee recommended the former plan, including the acquisition by the Government of all suitable existing floating equipment and the construction of such additional boats as conditions demanded, it being thought that most immediately efficient results could be secured with the Government operating these fleets so that they would be actually integrated with nearby railways and highways.

Concurring in these views the Director General directed the commandeering of all privately owned craft, and set up the necessary organizations in order that operations might commence immediately on these three waterways.

This action resulted in the assembling of a very mixed collection of floating units, many of which were extremely inefficient and in poor operating condition. Nevertheless these boats made possible the initiation of freight movements by water on a scale much larger than had previously been possible.

It was not the purpose of the Railroad Administration, however, to depend on these chartered boats, and at the same time these lines were inaugurated the construction of fleets of larger and better barges and towboats was undertaken, with which equipment it was proposed to conduct more economical and efficient freight transportation.

Building-program estimates were made of the earnings, but as a matter of actual fact these were not realized and the maintenance of the lines by the Government was a hard, up-hill fight.

The routes are today serving as avenues for transporting thousands of tons of merchandise every month, at an average of 20 per cent below our rates for similar hauls. The most important things which the lines are doing are to awaken widespread public interest in the possibilities of waterway transportation, to educate the shipper in the advantages of routing shipments by water, to demonstrate the classes of merchandise best suited for water haulage and the types of boats best adapted, to indicate the necessity for waterway terminals, and to pave the way for a mutually profitable basis of interchange between the railroad and water carriers.

Congress has already appropriated $2,000,000 to be spent within the next year in building necessary terminals. These projects must stimulate similar construction by private capital. Once these individual lines have reached the stage where they are actually producing profits, the physical operation of the lines may well be given over to private ownership on much the same basis as the Shipping Board is disposing of its war fleets. Until that time, however, the money spent by the Government in pioneering the way toward profitable large-scale waterway transportation may be considered as an investment which will in the near future bring splendid returns.

THE TRANSPORTATION AND TERMINAL PROBLEM OF NEW YORK AS AFFECTED BY THE HUDSON RIVER

By GUSTAV LINDENTHAL,[1] NEW YORK, N. Y.

THE transportation of Greater New York has been the subject of study and plans for many years. That part of the problem which has been touched upon less than might be expected from its importance is the transportation needs and facilities for about 2,000,000 population in New Jersey, within a radius of 15 to 20 miles from the City Hall in New York City. That population separated by the Hudson or North River is a tributary to the city life of Manhattan in the same degree as the 2,500,000 population living on Long Island, separated from New York City by the East River.

To the problem of local passenger transportation across the North River, however, must be added the big problem of passenger and freight transportation from seven large railroad systems reaching out South and West over the American continent and bringing in food, fuel and materials for Greater New York on thirty railroad tracks, humming with traffic day and night.

The Hudson River is a barrier which must be crossed daily by 700,000 passengers, 3,000 freight cars and 8,000 to 10,000 vehicles. Of the passengers about one-half come through the tunnels, all the rest of the passengers, all vehicles and all railroad cars come over as they did 80 years ago, on floating equipment along a river front of 12 miles.

If the traffic crossing the Hudson River were accommodated in the same proportion as it is across the East River at least 20 additional subfluvial tubes would be required, costing around 400 million dollars. The cost of a bridge erected at or below 59th Street, Manhattan, where shores are favorable, is estimated at 100 million dollars.

One of the most effective means of distributing the passenger traffic at the Manhattan end of such a bridge would be a moving platform which would intersect every line, in subway, on elevated or on surface, running north and south, to which a passenger might change. Such a moving platform, at a moderate speed of nine miles per hour, would have a carrying capacity of 40,000 passengers per hour in each direction. The moving platform would be a most important and indispensable feature of the bridge across the North River.

The eight heavy railroad tracks connecting with the seven large railroad systems on the New Jersey side can be used alternately for rapid-transit cars or for through trains. If these eight tracks were connected with an elevated marginal railroad extending along the west side of Manhattan and looped at both ends, and if this West Side railroad were connected by a subway two-track tunnel with a similar East Side marginal railroad, the transportation capacity would be 200,000 passengers per hour. There would be on the bridge alone a potential transportation capacity of 500 million passengers per year, not including highway passengers.

The local passenger traffic out to a distance of 20 to 30 miles in New Jersey could be kept separate from through passenger traffic on all the railroad lines by accommodating the through traffic in a detached union passenger station, located close to the New York end of the bridge.

[1] Consulting Engineer.

This freight traffic as well as the passenger traffic is growing at the rate of over 10 per cent per year. At least 60 per cent of the food for a population of six million is brought on these railroads from the western and southern states. The capacity of the bridge and stations for freight would be sufficient to handle 2000 freight cars per day each way, which leaves a large margin for growth.

In laying out the plans for freight it is expected to have the coöperation of the city authorities, who are especially interested in the building of market halls at short distances from each other where the public can buy fresh food cheaply and with great convenience.

Total Cost of Plan

The estimated cost of the bridge and the various connecting systems and equipment is as follows:

a Classification yard in New Jersey meadows and approaches to North River Bridge	$ 15,000,000
b Multiple-track high-level bridge over the North River	100,000,000
c West Side Elevated R.R. in Manhattan, 8 tracks, with stations and market halls, $4^1/_2$ miles long	20,000,000
d Connection with New York Central going north at 57th St	8,000,000
e Union station in Manhattan	30,000,000
f Moving (conveyor) platforms under 57th St	10,000,000
g Power-plant equipment and locomotives	30,000,000
Total	$213,000,000

This is not a large sum compared with the cost of nearly 500 million dollars for subways in Manhattan and Brooklyn for merely local passenger transportation, but which has reached the astonishing figure of 1600 million passengers per year with a gross revenue of 80 million dollars.

Revenue and Financing

From a thorough investigation for many years, the conclusion has been arrived at that the interests of the public would be best served by a separate terminal organization acting as an agent and trustee of the Federal Government. It is unquestionable that private capital can build and operate this undertaking quicker, cheaper and more efficiently than it can be done with public funds, but the ultimate title to the structure after amortization should be held by the United States Government.

The time for preparing agreements and plans and for the construction of this gigantic work is estimated at seven years. The trustees of the undertaking should comprise the best managers of railroads, of shipping, of warehousing and of finance.

The gross revenue is estimated at over 45 million dollars, which would leave after expenses of operation a net income big enough to meet all fixed charges and a substantial margin for amortization and profit. The incidental benefits in the increase of real-estate values would be experienced on both sides of the river, but the bridge would undoubtedly make of northern New Jersey a new country.

TRANSPORTATION

By J. R. BIBBINS,[1] CHICAGO, ILL.

To discuss transportation as broadly as possible, the producing territory of the country should be considered as a drainage basin, with the tonnage gravitating to various destinations. There are two distinct problems, namely, (1) the interstate movement from the districts of origin to districts of consumption; and (2) the transcontinental movement to port.

Illinois is the approximate center of population and Chicago is the major inland gateway. About 25 per cent of the major production of the country and probably of the Mississippi Basin was exported in normal prewar times, mostly to countries north of

[1] Consulting Engineer, Chief Assistant, Bion J. Arnold, Mem.Am.Soc. M.E.

ward bound, in the months following there is a preponderant movement of homeward-bound empties.

All the traffic is obliged to filter through the various gateways or terminals and much of it through seaboard terminals where the local and export traffic of the seaboard cities must also be handled. Therefore the rail terminals of the country must be called on to handle a large majority of the nation's tonnage, and accordingly their design and operating plan must proceed toward enlargement and perfection in accordance with the growth of the business of the country.

A prewar analysis of this growth indicates:

a Population last doubled in 37 years, since 1883

b Train mileage last doubled in 23 years or increased as the square of the population

c Passenger traffic last doubled in about 13 years or increased as the cube of the population

d Freight tonnage last doubled in 11 years or increased as the fourth power of the population

While this approximate geometric progression must gradually recede or else reach impossible figures, it is nevertheless patent that we are dealing with a profound forward movement which involves the very life of the nation and which should not be permitted to suffer artificial retrenchment.

The tonnage movement of the country does not move in accordance with the minimum cost of transport, but is affected by the following causes:

a Shipping facilities, frequent and scheduled

b Banking facilities for underwriting cargo

c Balanced cargo movements, in and out

d Port-terminal capacity and special facilities

e Established precedent, commerce and transport.

In the terms of worldwide transportation the vector diagram of transport movement is east-west and north-south. At present the resultant is unquestionably north and east. Here indeed is a problem for serious future consideration.

It is a curious fact that not one major railroad trunk line runs direct from the great northwestern producing lands to New Orleans, the major southern watergate. This omission is significant and will probably not be corrected until transportation is conceived as a whole on broader lines and the nation begins to think in worldwide terms rather than in the purely empirical terms of established local precedent.

A comprehensive discussion of national transportation cannot neglect the important factors concerned with international waterways and port terminals. Perhaps no more definite and tangible result can be secured than by concentrating attention on the traffic gateways.

The economic survey has for some years been used in the manufacturing and utility fields. Is there any reason why the railroad should not adopt the same method to perfect the transport organization of the country along perhaps broader and more economic lines than in the past? Such an economic survey would reveal all the invaluable facts and figures in the various movements between origin and destination. In the writer's experience at least one survey has revealed these complete facts for an entire metropolitan port district. For example:

a Terminal organization, relative efficiency and desirable improvements

b Belt lines, yards and interchanges, proper location

c Relation to the city plan

d Coördination of rail, barge and marine operations

e Administration, finance and accounting, best form.

The time seems opportune to ask for some compensation for the economic isolation of the interior and perhaps at the present moment attention might be centered on the question of a comprehensive study of steam and water transport on a comparative basis. But this study will be worse than useless unless it is conducted with the object of ascertaining the complete facts, not only of technical but of economic and equitable nature.

Test Code for Evaporating Apparatus

Preliminary Draft of the Third of a Series of Nineteen Codes in Preparation by the A.S.M.E. Committee on Power Test Codes

IN 1918 the Power Test Committee of the A.S.M.E. was reorganized to revise and enlarge the Power Test Codes of the Society, published in 1915. The Committee is a large one, under the chairmanship of Fred R. Low, and under its direction are 19 individual committees of specialists who are drafting codes for the different classes of apparatus comprised in power-plant equipment. Below is reproduced the third of these codes to be completed, namely, the Test Code for Evaporating Apparatus.

This Committee will, of course, welcome suggestions for corrections or additions. These should be mailed before April 1 to the Chairman, care of The American Society of Mechanical Engineers.

Test Code for Evaporating Apparatus

Introduction

1 This Code of Tests of Evaporating Apparatus is intended primarily for apparatus heated by steam, such as vacuum pans, or single- and multiple-effect evaporators. The principal use for such evaporators is in the manufacture of alkali, salt, sugar, condensed milk, extracts from chemicals, and similar processes.

Objects

2 The objects of the test should be clearly defined before preparations are made. Some of the purposes for which tests of this character are made are to determine:

(a) The adaptability of the apparatus to the material to be concentrated
(b) The most feasible and practicable method or methods of operation
(c) The maximum and minimum range in capacity of the evaporator consistant with economical operation
(d) The efficiency of the apparatus as a whole, and of its several elements
(e) Relative capacity and efficiency of the apparatus compared with other apparatus doing similar work
(f) The location of losses which may be minimized or eliminated by improved apparatus or better methods.

Measurements

3 The measurements involved in the testing of evaporating apparatus heated by steam will depend to some extent upon the object for which the test is conducted as defined in Par. 2 above. In general, these measurements will include the following:

(a) The general data relative to type of apparatus, and principal dimensions as defined in Table A, Items 7 to 20
(b) The weight or volume of the liquor before and after each effect, and for the apparatus as a whole
(c) The weight or volume of the steam to each effect and to the apparatus as a whole; also to any auxiliary apparatus
(d) The pressure, temperature and quality of the steam to each effect; also to any auxiliary apparatus
(e) The temperature, specific heat, and specific gravity of the liquor before and after each effect, and before and after the unit as a whole
(f) The weight or volume of water evaporated from the liquor
(g) The weight or volume of condensing water used.

Instruments and Apparatus

4 The apparatus and instruments required for testing evaporating apparatus will include:

(a) Tanks and platform scales for weighing liquor and water, or calibrated tanks, or meters
(b) Pressure and vacuum gages
(c) Thermometers
(d) Calorimeters for determining the quality of steam
(e) Hydrometers for determining the specific gravity of the liquors, and degree of concentration
(f) Apparatus for analyzing the liquors
(g) Barometer
(h) Electrical instruments, including voltmeter, ammeter, and wattmeter, if electrical measurements are necessary.

NOTE: For a full description of the use, calibration and accuracy of these instruments and pieces of apparatus, refer to the Code on Instruments and Apparatus.

Preparations

5 The General Instructions, Pars. 4 to 8, should be read, and preparations made accordingly, in so far as these instructions apply to the apparatus to be tested. Take the dimensions of the apparatus and the auxiliaries; note their physical condition; examine for leakages; select and install the testing appliances.

For the heating surface of the evaporating apparatus, measure the surface in contact with the steam, the liquor being in contact with the opposite side.

Where the apparatus is subject to vacuum, examine for leakage of air.

To test for air leaks close up and blank off the apparatus. Pump the air out of the apparatus, blank off vacuum pump, and see if air leaks are noted by decrease in vacuum. Small leaks difficult to find may usually be located by painting the joints and the surfaces, if porous, with a good quality of white lead.

Operating Conditions

6 Determine the operating conditions necessary to conform to the object of the test, and see that these conditions are maintained throughout the test.

Starting and Stopping

7 The pressures, temperatures, densities of liquors, and volumes of same within the evaporator should be the same at the beginning and at the end of the test. The test should be started at the beginning of a commercial cycle where such cycles exist in the operation of the evaporator, and after running the required number of hours it should be stopped at the beginning of the next succeeding cycle.

Duration

8 The duration of the test should depend upon the degree of accuracy demanded by the object for which the test is made. In no case should the duration be less than the regular commercial operating cycle. If the cycles are less than four hours in duration the test should cover at least three complete cycles, and the results of each cycle should substantially corroborate the other two. When the cycles are of four or more hours' duration the test should cover at least two complete cycles and these should be substantially corroborative. Should the operation be carried on in shifts the test should continue at least one calendar day of 24 hours. This length of time should be the duration when the supply of liquor or steam is irregular or intermittent, or when for any reason the regularity of the operation cannot be maintained.

Records

9 The data should be taken and recorded in the manner described in the General Instructions, Pars. 20 to 30. Half-hourly readings of the various instruments will be sufficient, except where there is considerable fluctuation in such readings, in which case more frequent readings must be taken in order to give good averages.

Uniformity of operation may be assisted by the plotting of a chart while the test is in progress, as pointed out in Par. 29 of General Instructions.

10 The data and results should be tabulated in accordance with the form shown in Table A, forming part of this Code, adding items not provided for and omitting items not needed to conform to the object in view. Unless otherwise indicated, the items refer to the numerical averages of the readings which are recorded in the log.

The methods of calculating the results as tabulated, so far as not self-evident, or not sufficiently indicated in the text for the items, are explained in the following section.

Calculation of Results

Liquor Levels (Table A, Item 28). The datum from which

degrees of the liquor in any effect is the difference between the boiling temperature of the liquor in that effect and the boiling temperature of water under the same pressure as that of the vapor in the effect.

11 *Steam to Condenser* (Table A, Item 52). This cannot be measured directly. If a surface condenser is used this item can be determined by measuring or weighing the condensed steam discharged from the condenser. If a jet condenser is used, Item 52 may be calculated from the weight of condensing water and the rise in temperature of the condensing water. The product of these two will give the heat transferred to the condensing water, and this heat divided by the heat in a pound of steam going to the condenser, reckoned from the temperature at which the condensing water leaves the condenser, will give the weight of steam going to condenser. The same item may be determined by taking the difference in weight between feed and discharge liquors in the last effect.

If any retained product is found in the steam to the condenser, this must be taken account of in calculating the weight of steam going to condenser.

12 *Evaporation from Liquor* (Table A, Item 53). This is the sum of the steam to the condenser (Item 52) and the condensed steam drained from the effects, except that from the first effect. [Total of Item 61, except (*a*)].

13 *Liquor Entering* (Table A, Item 56). The weight of liquor entering the first effect is the weight of the feed liquor.

In case it is possible to measure the liquor passing from one effect to the next by pitot tube, venturi tube, or other device, the weight of the liquor entering each effect may be calculated from such measurement, and the temperature and specific-gravity test of the measured liquor. If the condensate can be measured, the liquor entering any effect can be calculated by subtracting the weight of the condensate from the feed liquor, or the liquor entering the previous effect. If it is impossible to measure the liquor passing from one effect to the next, the sub-items of No. 56, except (*a*), had better be omitted, as the calculation of these items is very unsatisfactory.

14 *Evaporation from Liquor in Individual Effects* (Table A, Item 58). The satisfactory determination of the several sub-items of this number, except in the case of a vacuum pan, or single effect, depends upon the successful measurement, or calculation, of the liquor passing from one effect to the next. If the liquor can be measured the evaporation in each effect is determined by taking the difference in weight of the liquor entering and leaving that effect (Items 56 and 57), or by measuring the condensate directly.

15 *Evaporation from Liquor from and at 212 Deg. Fahr.* (Table A, Item 53). This is Item 68 ÷ 970.4.

16 *Self-Evaporation* (Table A, Item 59). Self-evaporation in any effect is determined as follows: Multiply the weight of the liquor entering that effect by the temperature drop between the boiling point in that effect and the boiling point in the preceding effect, and by the specific heat of the liquor. Divide this quantity by the latent heat of evaporation in the effect considered. The result is the weight of self-evaporation.

17 *Heat Contained in Entering Liquor* (Table A, Item 63). This is the pounds of feed liquor multiplied by the temperature above 32 deg. fahr. of the feed liquor, and this product multiplied by the specific heat of the feed liquor.

18 *Heat from Steam Supplied to Entire Apparatus* (Table A, Item 64). This is the sum of the products of the pounds of steam, from Items 42, 43 and 44, multiplied respectively by the total heat, above 32 deg. fahr., in a pound of steam of the pressures and qualities used.

19 *Heat to Pumps* (Table A, Item 65). This is the product of the pounds of steam to pumps, Item 44, by (the heat units in a pound of live steam to pumps minus the heat units in one pound of exhaust steam from pumps corrected for quality).

20 *Heat Contained in Discharge Liquor* (Table A, Item 66). This is the product of the pounds of discharge liquor (Item 51) by the temperature, above 32 deg. fahr., of the discharge liquor, and the weight of steam to condenser (Item 52) and the heat units in a pound of this steam; otherwise this item must be calculated from the heat absorbed by the condensing water; or, pounds of condensing water (Item 62) multiplied by rise in temperature of condensing water [Item 37 (*b*) — 37 (*a*)]. To this must be added the heat in the condensate above 32 deg. fahr.

22 *Heat Contained in the Evaporation from Liquor* (Table A, Item 68). This is the heat in the steam going to the condenser, plus the heat in the condensed steam drained from the effects (except that drained from the first effect: Item 67 + (Item 73 — Heat in condensed steam from first effect).

23 *Heat Contained in Entrained Product* (Table A, Item 69). From the analysis of the steam to the condenser (Item 92) the amount of entrained product is determined. The weight of this entrained product, multiplied by its temperature above 32 deg. fahr., and this product, multiplied by the specific heat of the entrained product, will give the heat in such product escaping with steam to condenser.

24 *Heat Supplied to Heaters* (Table A, Item 70). This is the product of the pounds of live steam to heaters (Item 42) by the total heat above 32 deg. fahr. in a pound of such live steam. To this must be added the heat supplied from exhaust steam, if any. This is the product of the pounds of exhaust steam to heaters (Item 47) by the total heat above 32 deg. fahr. in a pound of such exhaust steam. In determining the heat in the steam the quality of the steam must be taken into account.

25 *Heat in Water from Heaters* (Table A, Item 71). This is the product of the pounds of water discharged from heaters (Item 60) by the temperature of such water above 32 deg. fahr.

In case of more than one heater the heat will need to be calculated for each heater separately and the sum of the several quantities taken.

26 *Heat Supplied to the Effects* (Table A, Item 72). This is the product of the pounds of live steam to the effects (Item 43) by the total heat above 32 deg. fahr. in a pound of such live steam. If exhaust steam is supplied to the effects its heat must be added to the above. Pounds of exhaust steam (Item 48) multiplied by the total heat, above 32 deg. fahr., in a pound of exhaust steam.

27 *Heat in Condensed Steam Drained from Effects* (Table A, Item 73). This is condensate taken from the steam space of an effect. In case of more than one effect this should be passed along to the next effect if possible, where its heat may, in part at least, be transferred to the liquor. This heat is the product of pounds of condensed steam [Item 57(*b*)] multiplied by the temperature above 32 deg. fahr. of such condensate. In case the apparatus has more than one effect the heat must be calculated for each effect separately, and the sum of the several quantities taken.

In case the condensed steam flows from the steam space of one effect to that of the next effect its temperature should be measured at point of leaving the last effect of the series. This temperature, in degrees above 32 deg. fahr., multiplied by the pounds of condensed steam leaving the last effect will give the heat in the total condensed steam drained from the effects.

28 *Heat Discharged from the Effects* (Table A, Item 74). This is the sum of Items 66, 67, 68 and 73.

29 *Apparent Heat-Transmission Coefficients*. The apparent heat-transmission coefficient in any effect is obtained by dividing the total heat transmitted per hour in that effect by the heating surface in that effect, and by the apparent temperature drop. The apparent temperature drop is the difference between the temperature corresponding to the pressure of the heating steam and the temperature corresponding to the pressure in the vapor space of the effect.

The total heat *transmitted* in any effect is not the heat corresponding to the evaporation in that effect. It is less than this quantity by the heat in self-evaporation. The total heat *transmitted* is therefore determined by subtracting from the total evaporation (Item 58) the self-evaporation (Item 59), and multiplying this difference by the total heat (above the temperature of the vapor) in one pound of steam at the pressure and temperature of the vapor in the effect.

30 *Corrected Heat-Transmission Coefficients* (Table A, Item 82). Apparent heat-transmission coefficients, as outlined in Par. 29, may be corrected for

(*a*) Excess boiling degrees
(*b*) Hydrostatic head
(*c*) Both excess boiling degrees and hydrostatic head.

The report should clearly specify which of these corrections have been made.

If a coefficient is to be corrected for excess boiling degrees, the heat transmitted as explained in Par. 29, is to be divided by the heating surface and by the temperature drop between the temperature corresponding to the pressure in the heating space and the actual boiling point of the surface liquor in the effect in question.

If a coefficient is to be corrected for hydrostatic head the total heat transmitted, as explained in Par. 29, is to be divided by the heating surface and by the temperature difference between temperature corresponding to the pressure in the heating space and the boiling point of the liquor at the mid-point of the hydrostatic head. This last temperature is to correspond to a pressure equal to the pressure of the vapor space plus a pressure due to a column of liquor equal to one-half the hydrostatic head.

FINAL REPORT

Evaporative Ratio and Efficiency of Individual Effects

31 *Overall Thermal Efficiency of the Entire Equipment* (Table A, Item 75). This is the ratio of the heat contained in the total evaporation from liquor, to the heat from steam supplied to entire apparatus. Item 68 divided by Item 64, and the quotient multiplied by 100 to give percentage.

32 *Thermal Efficiency of the Effects* (Table A, Item 76). This is the ratio of the heat contained in the evaporation from liquor to the heat supplied to the effects. Item 68 divided by Item 72, and the quotient multiplied by 100 to give percentage.

If the evaporation from liquor in each effect [Item 58(*b*)] is calculated, then these figures, with those of Item 61(*b*), may be used to check the above quantity of heat in steam evaporated from liquor, or to figure the efficiency of each effect, and of all effects.

33 *Thermal Efficiency of Heaters* (Table A, Item 77). This is the ratio of the heat put into the liquor in its passage through the heaters to the heat supplied to the heaters.

Item 50 multiplied by [Item 33(*a*) — Item 32(*a*)] and by the specific heat of the feed liquor.

The above product divided by Item 70, and this quotient multiplied by 100, will give percentage.

Economy

34 *Evaporation Per Pound of Total Steam Used* (Table A, Item 83). This is Item 51 ÷ Item 45.

35 *Evaporation from and at 212 Deg. Fahr. Per Pound of Total Steam Used* (Table A, Item 85). This is Item 54 ÷ Item 45.

TABLE A—DATA AND RESULTS OF EVAPORATING APPARATUS TEST

(*A.S.M.E. Code of 1920*)

General Information

(1) Date of test ...
(2) Kind of apparatus under test (vacuum pan, multiple-effect evaporator, etc.) ...
(3) Location ...
(4) Owner ...
(5) Builder of apparatus ...
(6) Test conducted by ...

Description, Dimensions, Etc.

(7) Type of apparatus ...
(8) Dimensions of shells ...
(9) Material of tubes and tube sheets ...
(10) Number of tubes in each effect ... { Length ... / Diameter ...
(11) Heating surface in each effect ... sq. ft.
(12) Number and type of liquor heaters ...
(13) Number of tubes in each heater ... { Length ... / Diameter ...
(14) Heating surface in each heater ... sq. ft.
(15) Liquor heating surface in each heater ... sq. ft.
(16) Type and make of condenser equipment ...
(17) Condensing surface ... sq. ft.
(18) Type and dimensions of vacuum and circulating pumps ...
(19) Kind of liquor concentrated ...
(20) Characteristics of liquor concentrated ...

Test Results

(21) Duration of test ... hr.

Average Pressures and Temperatures

(22) Steam pressure by gage ... lb. per sq. in.
(23) Barometric pressure ... in. of mercury
(24) Absolute steam pressure ... lb. per. sq. in.
(25) Pressure in exhaust-steam line from pumps ... lb. per sq. in.
(26) Pressure or vacuum:
  (*a*) 1st effect ... lb. pressure ... in. vacuum
  (*b*) 2nd effect ... lb. pressure ... in. vacuum
  (*c*) 3rd effect ... lb. pressure ... in. vacuum
  (*d*) 4th effect ... lb. pressure ... in. vacuum
  (*e*) 5th effect ... lb. pressure ... in. vacuum
  (*f*) 6th effect ... lb. pressure ... in. vacuum
(27) Vacuum in the condenser ... in. of mercury
  (*a*) Corresponding absolute pressure ... lb. per sq. in.
(28) Liquor levels:
  (*a*) In 1st effect ... inches
  (*b*) In 2nd effect ... inches
  (*c*) In 3rd effect ... inches
  (*d*) In 4th effect ... inches
  (*e*) In 5th effect ... inches
  (*f*) In 6th effect ... inches
(29) Temperatures of saturated steam corresponding to the vapor pressure in:
  (*a*) 1st effect ... deg. fahr.
  (*b*) 2nd effect ... deg. fahr.
  (*c*) 3rd effect ... deg. fahr.
  (*d*) 4th effect ... deg. fahr.
  (*e*) 5th effect ... deg. fahr.
  (*f*) 6th effect ... deg. fahr.
(30) Steam temperatures:
  (*a*) Superheated steam ... deg. fahr.
  (*b*) Normal temperature of saturated steam ... deg. fahr.
  (*c*) Temperature of exhaust steam ... deg. fahr.
(31) Temperature of liquor:
  (*a*) Entering 1st heater ... deg. fahr.
  (*b*) Entering 2nd heater ... deg. fahr.
  (*c*) Entering 3rd heater ... deg. fahr.
  (*d*) Entering 4th heater ... deg. fahr.
  (*e*) Entering 5th heater ... deg. fahr.
  (*f*) Entering 6th heater ... deg. fahr.
(32) Temperature of liquor:
  (*a*) Entering 1st effect ... deg. fahr.
  (*b*) Entering 2nd effect ... deg. fahr.
  (*c*) Entering 3rd effect ... deg. fahr.
  (*d*) Entering 4th effect ... deg. fahr.
  (*e*) Entering 5th effect ... deg. fahr.
  (*f*) Entering 6th effect ... deg. fahr.
(33) Temperature of liquor:
  (*a*) Leaving 1st effect ... deg. fahr.
  (*b*) Leaving 2nd effect ... deg. fahr.
  (*c*) Leaving 3rd effect ... deg. fahr.
  (*d*) Leaving 4th effect ... deg. fahr.
  (*e*) Leaving 5th effect ... deg. fahr.
  (*f*) Leaving 6th effect ... deg. fahr.
(34) Excess boiling degrees of liquor:
  (*a*) In first effect ... deg. fahr.
  (*b*) In 2nd effect ... deg. fahr.
  (*c*) In 3rd effect ... deg. fahr.
  (*d*) In 4th effect ... deg. fahr.
  (*e*) In 5th effect ... deg. fahr.
  (*f*) In 6th effect ... deg. fahr.
(35) Temperatures of condensed steam discharged:
  (*a*) From 1st heater ... deg. fahr.
  (*b*) From 2nd heater ... deg. fahr.
  (*c*) From 3rd heater ... deg. fahr.
  (*d*) From 4th heater ... deg. fahr.
  (*e*) From 5th heater ... deg. fahr.
  (*f*) From 6th heater ... deg. fahr.
(36) Temperatures of condensed steam:
  (*a*) Drained from 1st effect ... deg. fahr.
  (*b*) Drained from 2nd effect ... deg. fahr.
  (*c*) Drained from 3rd effect ... deg. fahr.
  (*d*) Drained from 4th effect ... deg. fahr.
  (*e*) Drained from 5th effect ... deg. fahr.
  (*f*) Drained from 6th effect ... deg. fahr.
(37) Temperature of condensing water:
  (*a*) Entering condenser ... deg. fahr.
  (*b*) Leaving condenser ... deg. fahr.
(38) Temperature of air in evaporating room ... deg. fahr.
(39) State of weather:
  (*a*) Temperature of external air ... deg. fahr.
  (*b*) Relative humidity of external air ... per cent

James Watt International Memorial

The Society's check for 250 guineas, the total of the individual subscriptions received from members in response to the appeal issued by the James Watt International Memorial Committee, has been forwarded to Birmingham, England.

A few late subscriptions are still being received and these will be forwarded in a lump sum later. Any members of the Society who have not yet done so, may still send in their subscriptions to the Secretary and their names will be recorded on the list of individual subscribers and sent to Birmingham as soon as compiled.

Chicago Engineers, Attention!!

The following appears at the head of the editorial page of the Chicago *Tribune*. Evidently the editor of the *Tribune* sees clearly that the development of Chicago is an engineering job and that the solution of the engineering problems he enumerates will result in a bigger, cleaner, more moral city.

The Tribune's Platform for Chicago

1—Lessen the Smoke Horror.
2—Create Modern Traction System.
3—Modernize the Water Department.
4—Build Wide Roads Into the Country.
5—Develop All Railroad Terminals.
6—Push the Chicago Plan.

INDUSTRY'S SUPPLY OF ENERGY

(Continued from page 166)

great efficiency, but even in Europe and North America only about one-fifth of the potential power has yet been developed. To that extent only have we succeeded in "borrowing the might of the elements" "for the use and convenience of man," but we may expect our rivers to take on an even larger share of the base load in any power program that seeks to conserve the energy supplies in coal, oil, and men. Of course, even with wisest utilization, coal must again take up the burden as full development of water power is approached, for coal is the world's great source of heat and power, and the largest development of water powers is practicable only with coal power as the dependable "stand-by," ever ready to meet promptly any special demand.

Oil and natural gas are the popular fuels, regarded as highly efficient because they are preeminently labor-saving—easily produced, easily transported, and easily used. As source of power these fluid fuels present a marked contrast with water. Hydroelectric energy is even more easily distributed and used, but water-power development involves large capital outlay and in any national emergency no quick response in water power is possible; the water-power projects planned to meet the power needs discovered in the course of our wartime expansion of industry are even now hardly under way. But when the large necessary investment of labor and material is once made in water power the output of energy continues for generations. Oil and gas, on the contrary, are quickly developed and quickly exhausted. Already we realize that natural gas, the ideal fuel, is a resource so temporary that its use forms merely an incident in industrial progress; it has been a wasted as well as a wasting resource. The sorry lesson we have learned in natural gas may have its value if we apply the truth to our use of oil. Unless we check the increase in the consumption of oil it too will be but a flash in the pan.

If we leave the world point of view for a moment and look at the power problem in our own country we are able to see in more detail the relative position of water, coal, and oil as sources of energy. Millions of horsepower, thousands of billions of tons, and billions of barrels are the measures of our nation's wealth in these three resources, yet no comparison is possible except as we reduce these units to a common denominator—something more expressive of true value, which is their use by man. Indeed, such statistics of quantity are too large to be grasped unless we translate them into some kind of national units.

To compare these three resources, then, we may start with the country's present total power requirements: if we take 50 million horsepower as an average figure for the potential water power of the United States, without storage, we find that if fully developed and if used at the average load factor of today our rivers and streams would just about meet the country's present needs and would supply that amount of power for all time; moreover, with storage and an improved load factor they could provide a considerably increased output of energy to meet the growing demand.

Now if, leaving our water-power resources to one side—indeed we have already left them aside too long, we try putting the whole power burden on our coal mines we are able to make a direct comparison between our coal resources and our potential water powers. There is in the United States accessible and available for future use an aggregate of about 2500 billion tons of coal, not including lignite. Only about one-fifth of this is in the Eastern States, another fifth is in the coal fields of the Central States, and nearly three-fifths is in the Rocky Mountain and Western States. In converting these great reserves of coal into power I did not allow directly for the greater differences in the thermal value of the coals, but instead of figuring B.t.u. and thermal efficiency of prime movers, I reached somewhat the same result by using the best central-station practice of today on the Atlantic seaboard, here in the Central States, and in the Rocky Mountain region. Incidentally, I found myself using a new unit, the horsepower-century, for which the equivalent in eastern coal is 250 tons, in interior coal 300 tons, and in western coal, 350 tons. By applying these factors to our estimates of reserves we get 2240 million horsepower-centuries, 1750 million horsepower-centuries, and 4171 million horsepower-centuries, respectively, or a total of 8161 million horsepower-centuries. I should add that a million horsepower-centuries is seven times the present power output of the United States. So you will see that by adopting the best steam practice of today the present power requirements of this country could be met with coal for 57,000 years, although we know that long before the end of that period the greater depth of the coal mines and their increased distance from market would alone create power demands for mining and transportation that would considerably cut down the amount of power available for other uses.

We measure the petroleum wealth of the United States by billions of barrels—about 5 billion already produced in the last 60 years, and about 7 billion left for the future. Again adopting the best steam practice of today in public-utility stations of Texas and California—a little less than 32 barrels to the horsepower-year—and trying to carry the whole power load of the country with oil alone, we find that the oil reserves of the United States, although measured by billions of barrels, would last only 9 years and 3 months. Without allowing for the fact that steam raising for power is only one of the many uses of coal, these two figures, 57,000 and $9^1/_4$ years, are sufficiently impressive to make us fairly receptive to the general truth of Mr. Eckel's statement in his recent book, Coal, Iron and War: "We have just as much real chance of replacing coal by oil as we have of finding enough gold to use it in place of steel."

Costs of Energy

These are comparative estimates of the energy supplies which may be tapped for the use of our own citizens, and before discussing their distribution, we should give a thought to the relative cost in human energy in making these three kinds of energy available. I need not tell an audience of engineers the differences in labor outlay in constructing a hydroelectric plant, opening up a coal mine, and drilling an oil well. Each is an engineering project that requires careful planning and the expenditure of money, skill, and labor, but in widely different amounts. Moreover, the water-power plant ought to last for generations and the coal mine for several decades, but the life of an oil well is measured by a few years. In operation, however, the water-power plant is a labor saver, and the best illustration of this fact is that balance sheet put out by the Alabama Power Company, which compares a large steam plant with a hydroelectric plant operated under the same management and feeding into the same transmission lines. In terms of 1000 kw. capacity it takes $13^1/_2$ men to run the steam plant and the coal mine tributary to it. And how many does it take for the corresponding units in the hydroelectric plant? One-sixth of one man. The exact ratio is 84 to 1. Another comparison with coal is afforded by the statement that in Mexico one man can produce and transport to market the oil equivalent of the coal that it would take 10 men in the United States to mine. These approximate comparisons of the labor cost of our different energy slaves may well be kept in mind as we plan or the larger use of mechanical power.

As mechanical engineers you are best fitted to grasp the national aspects of this energy-supply problem: you can see in true relations both the layout of the supply and the distribution of the demand. Better production is the country's need just now and you men are production engineers in the broadest sense. But, as you well understand, it is not enough for you and me to see the problems of the day and to understand them—that is simply a matter of our mental capacity—but what about performance? It strikes me that this matter of full utilization goes further than material resources or energy supplies: do we not need to raise our intellectual load factor? Is not there too great a gap between our peak practice and our average load? In a word, the engineer needs to be more of a citizen, or, as Herbert Hoover put it the other day, "Organize the engineering mind for expression in public service."

As the result of experience gained on the Santa Fe system, it is stated that the life of a boiler fired with coal is about 10 per cent greater than that of one fired with oil, while the life of the tube is about 40 per cent higher in the coal burners.

Recent Trend in Locomotive Design in Europe

VARIOUS influences are at work in Europe in the matter of locomotive design. There is a general feeling that the efficiency of locomotive operation must be increased, and that what was "good enough" in prewar days when fuel was cheap and labor plentiful, may not be good enough at all today, with things as they are.

Of great importance also is the leaven brought in through a greater familiarity with American design. European railroad men have seen the big American engines hauling immense loads in France, and while they are still prepared to find fault with some of their features at least, as far as they apply to European conditions, they have been quick enough to notice many things that are good.

The two English locomotives described in the following abstracts clearly show the influence of American practice, in addition to which they are of interest also as showing some of the original tendencies of British locomotive engineering.

The German internal-combustion locomotives described in the third abstract do not represent anything strikingly novel, but were considered worthy of attention mainly because the entire art of gasoline-locomotive construction is still in such a state of development that every bit of information is of value.

GREAT NORTHERN THREE-CYLINDER FAST-FREIGHT LOCOMOTIVE

Great Northern Three-Cylinder Fast Freight Locomotive. Features of this locomotive are the novel valve gear with comparatively early cut-off, designed to give high economy through a wide range of power, the use of three steam cylinders, a single plate for the barrel of the boiler, etc. The boiler itself is far larger than has been the British practice hitherto. Ball and roller bearings are used for certain joints in the valve gear, heat-treated chrome steel for connecting and coupling rods, and the locomotive altogether is probably more unlike the standard British practice than any which has yet been placed in service.

So far only one engine, No. 1000, has been placed into service, but nine others are under construction. This engine is a general-purpose one and handles both heavy passenger and heavy freight trains. The barrel of the boiler is made of a single plate $^5/_8$ in. thick measuring nearly 19 ft. long by nearly 11 ft. 6 in. broad. It has a butt joint with quadruple riveting through two butt straps, the inner strap being much wider than the outer. As a consequence two rows of rivets pass through both the straps and the plate, while the two other rows pass only through the inner strap and the plate. In tests it was found that the ratio of yield point of joint to yield point of material was no less than 93.7 per cent.

In the superheater, which is of the Robinson type, an anti-vacuum or snifting valve is placed just before the chimney and opens downward on the admission side of the header. Steam pressure raises and closes it, but when steam is shut off and the engine is drifting the valve drops and air is sucked through the superheater by the cylinders and discharged up the blast pipe which keeps the elements cool and the cylinders warm.

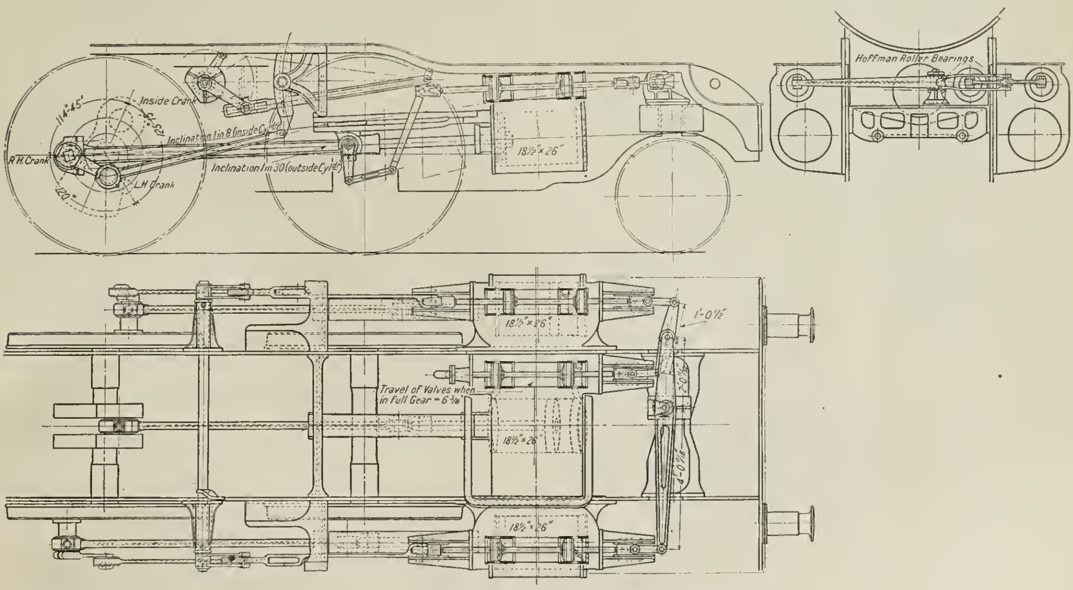

Fig. 1 Diagram of Gresley Valve Gear for Great Northern Railroad Engine No. 1000

The cylinder arrangement is shown in Fig. 4. The cylinders are almost horizontal (1 in 30), the inside cylinder alone being inclined at 1 in 8 to clear the leading axle. By placing the three valve chests in one straight line it was possible to use a very simple form of Gresley's valve gear.

The valve motion is shown by diagram, Fig. 1. The two outside cylinders are fitted with Walschaerts' gear. The tail rod of the right-hand valve is linked to a long lever which is fulcrumed on the front transom. This is a lever of unequal arms — 2 to 1. On its left-hand end is carried a floating lever of equal arms, one end of which is linked to the left-hand valve and the other to the inside

valve. The most striking feature about it is the great horizontal lever, over 6 ft. long between centers. It is made of steel and has been carved away to make it as light as possible. At the fulcrum it is fitted with a Hoffman ball and roller bearing, and a bearing of the same kind carries the floating lever. This lever, the only possible feature in the motion that could give rise to any anxiety, has proved perfectly satisfactory. An interesting little question in a gear of this kind is the effect of expansion of the valve rods by heating. Since the position of the two outside rods is fixed by the valve gear, they would transfer the effect of their elongation to the inside valve.

It is claimed that the expansion is so small that only $^1/_8$ in. has to be allowed for on the central valve and $^1/_{32}$ in. on the outside valves, all measured cold. The effect is less than might be expected, because the frames expand as well as the valve rods and carry the fulcrum of the big lever with them. The valve settings are given in Table 1. From this it would appear that a very early cut-off had been adopted for full-gear working, which is intended to permit to secure the full benefit from the use of the three-cylinder arrangement.

In this connection, attention may be called to the Pennsylvania Decapod locomotive described in The Journal of the American Society of Mechanical Engineers, August, 1917, p. 738. There a 50 per cent cut-off was employed, the purpose being to eliminate the range of cut-offs within which the water rate of the cylinder is excessive, and to make possible an increase in the ratio of cylinder power to boiler capacity. The Great Northern engine has its valves set to give a maximum cut-off of 65 per cent.

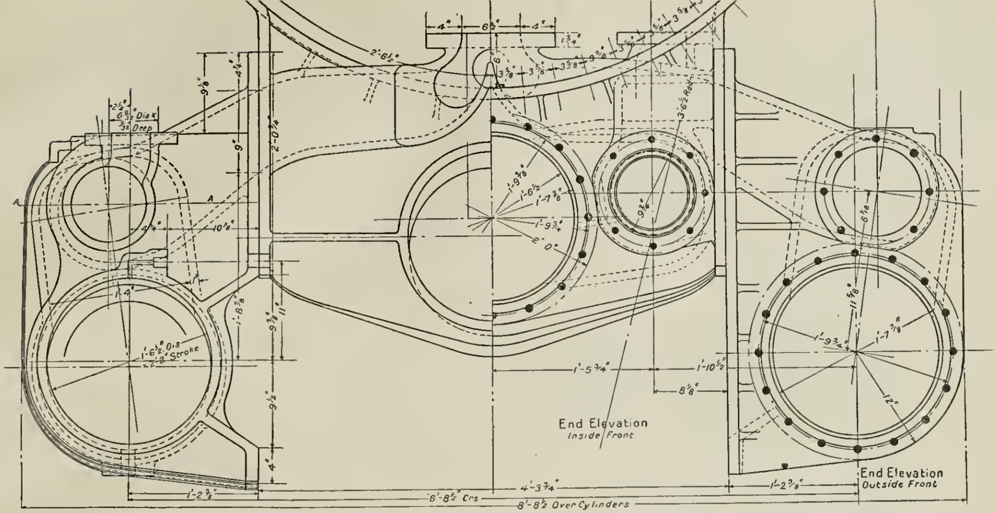

Fig. 4 Great Northern Locomotive Cylinder Arrangement

As it has three cylinders, no very large cylinder diameters need to be used in order to produce sufficient tractive force to absorb a proper percentage of the adhesive weight.

Fig. 3 shows the details of an outside connecting rod made of heat-treated chrome-nickel steel. The weights for the rods are as follows: Outside connecting rod, 295 lb.; inside connecting rod, 347 lb.; coupling rods, 471 lb. The following observation may be of interest: When chrome-nickel rods came back to the shop after heat treatment, it was noticed that they were strongly magnetic in the middle, but not at all at the ends. Furthermore, when the magnetism was examined, it was found that it was positive in the center and negative at the ends. A further investigation has shown, however, that this peculiarity was due to the fact that the rods had been handled by a lifting magnet of the familiar annular form.

In further reference to the boiler, it may be mentioned that the cross-stays above the firebox are carried by brackets riveted to the wrapping plate, and that thirty-two superheater tubes are used.

Particulars given by E. C. Poultney regarding the experience with this engine would indicate that the engine has given great satisfaction in most respects. This part of the article, however, is not suitable for abstracting. (*The Engineer*, vol. 130, no. 3392, Dec. 31, 1920, pp. 634–635, and one 2-page plate. Compare also May 7, 1920, pp. 466–472, illustrated, *dA*)

MIDLAND DECAPOD LOCOMOTIVE

Midland Decapod Locomotive. Fig. 5 shows a 10-wheel coupled banking engine placed by the Midland Railway, England, for service on the Lickey Incline.

Particular attention is called to the inclination of the cylinders, which apparently is coming into favor in England. Tests made in that country have shown that moderate inclination of the cylinders is disturbing only at very low speed.

In the Midland Decapod the evaporative surface in tubes is 1560 sq. ft. and in the firebox 158.25 sq. ft. The superheater area is 445 sq. ft. and the grate area 31.5 sq. ft. The tractive effort at 85 per cent boiler pressure is 43,312 lb.

In connection with British locomotive development generally might be mentioned the heavy tank engines recently placed in service by the Metropolitan Railway. The wheel arrangement, which is 4-4-4, gives a fixed wheelbase of 7 ft. 9 in., and enables the engine to take yard curves of only 4.5 chains radius. The total weight on the coupled wheels is 39 tons, and on each truck 19 tons, making 77 tons in all in working condition. The cylinders are 19 in. by 26 in., the wheels 5 ft. 9 in. in diameter, and the working steam pressure 160 lb. The engines are required to accelerate rapidly and haul trains of 250 tons, which their tractive effort of 17,400 lb. enables them to do. (*The Engineer*, vol. 131, no. 3393, Jan. 7, 1921, pp. 10-11, 2 figs., *dA*)

GERMAN INTERNAL-COMBUSTION LOCOMOTIVES

Internal-Combustion Locomotives and Their Industrial Applications. The need for satisfactory means of transportation of light loads at moderate speeds has already been felt for a long time in the mining industry where the available new types, such as fireless, compressed-air, and electric locomotives, have not been found entirely satisfactory. In such work the internal-combustion locomotive has proved superior to the types mentioned in many respects, and in Germany the Deutz Gas Engine Company has led in their development.

Fig. 6 shows side and end elevations of a Detuz internal-combustion mine locomotive equipped with chain drive. The engine is of the single- or multiple-cylinder 4-stroke-cycle type. Cooling is effected by evaporation, some of the water being led to the muffler for the condensation of the exhaust gases, the purpose of this being to render them odorless. This is particularly important in mine locomotives in order to prevent contamination of the air. In particular, in connection with the use of internal-combustion locomotives in mines, it is claimed that the contamination of air resulting therefrom is less objectionable than that consequent on the employment of animals for haulage purposes.

The transmission of power from the engine to the driving axle is carried out either by the chain and gear drive or by gear drive exclusively. If chain drive is employed (Fig. 7), then the power is transmitted from the engine A through the gear wheel R_1 secured firmly on the crankshaft, through the loose intermediate gear R_2 and thence to the gears R_3 and R_4. These latter are loose on the shafts B_1 and B_2 and run in opposite directions and at different speeds. On the other side the shafts B_1 and B_2 are interconnected by gear wheels R_5 and R_6 which are of equal diameters and held fast on their respective shafts. The arrangement is such that if either of the shafts is set into motion by the interconnected friction couplings C' or C'', both shafts must run in opposite directions and at speeds corresponding to the number of teeth in the gear wheels R_3 or R_4. Further on the shafts B_1 and B_2 are set the loose sprocket wheels D_1 and D_2 which may be connected rigidly with their respective shafts by means of appropriate claw clutches F_1 and F_2.

The driving axle is driven from the sprockets D_1 and D_2 by the chains G_1 and G_2. To change the running speed all that is necessary, therefore, is to change the engagement of the friction couplings, while to change the direction of running, the clutches F_1 and F_2 may be used.

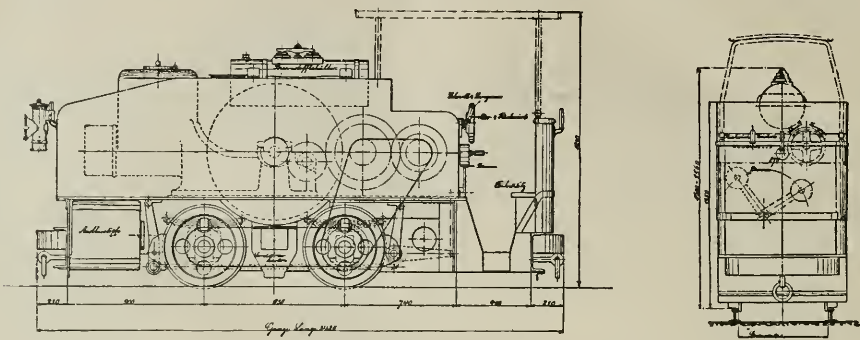

Fig. 6 Deutz Internal-Combustion Mine Locomotive

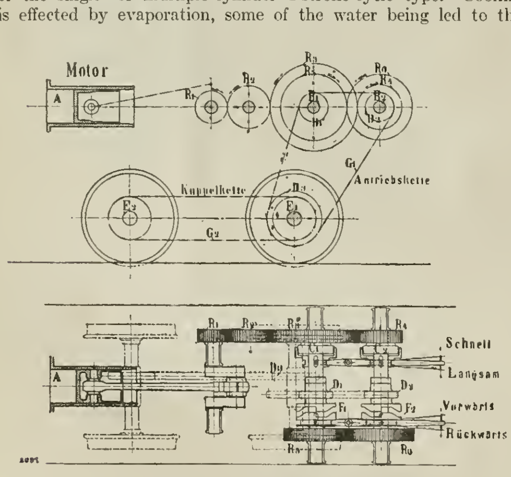

Fig. 7 Chain Drive of the Deutz Internal-Combustion Mine Locomotive (2-Speed Transmission)

(*Antriebskette* = driving chain; *kuppelkette* = transmission chain; *schnell* = high speed; *langsam* = low speed; *vorwarts* = forward; *ruckwarts* = reverse.)

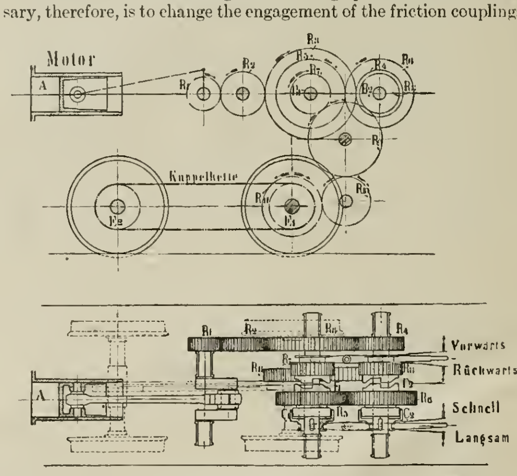

Fig. 8 Gear Drive of the Deutz Internal-Combustion Mine Locomotive (2-Speed Transmission)

(*Kuppelkette* = transmission chain; *schnell* = high speed; *langsam* = low speed, *vorwarts* = forward; *ruckwarts* = reverse.)

In the arrangement shown in Fig. 8 the same general construction is used as in the previous case but the drive is transmitted through the gears R_7 to R_{11} instead of through sprockets and chains.

Mine locomotives in Germany are built in sizes of from 4 to 5 hp. to as high as 60 to 70 hp. (First of a series of articles in *Oel-u. Gasmaschine*, vol. 17, no. 12, December 1920, pp. 177–180, 7 figs., *d*)

A Comparison of the Theories of Elongation and of Shear Stress, Prof. H. Bonte. When a machine part is stressed simultaneously in tension and torsion or bending and torsion there arise in it stresses as to the magnitude of which there is as yet no agreement.

In continental Europe these stresses are evaluated on the basis of the maximum elongations caused by them, which is in accordance with views dating back to St. Venant (theory of elongation). Since, however, the engineer has no direct way of determining the specific elongations, the actual elongation is simply multiplied by the modulus of elasticity E. In this way a value is obtained which may indicate the magnitude of the stresses present when the load on the body is applied along a single axis. The formula by which this stress is computed reads as follows:

$$k_z \geqq \sigma_i = 0.35\sigma + 0.65\sqrt{\sigma^2 + 4\tau^2} \qquad [1]$$

It is made to agree more closely with practical values by the application of the Bach method, in accordance with which the so-called "coefficient of effort" $\alpha_0 = k_z/1.3k_d$ is added to the shear stress τ, in which event the formula is written as follows:

$$k_z \geqq \sigma_i = 0.35\sigma + 0.65\sqrt{\sigma^2 + 4(\sigma\tau_0)^2} \qquad [2]$$

In this equation k_z(or k_d) is the permissible stress in tension (or torsion) for the given material under the given conditions, σ_i the ideal stress in tension as described above (elongation × modulus of elasticity), σ the maximum normal stress produced by the tension or bending, and τ the maximum shear stress produced by the torsion.

In England and America principal stresses computed in accordance with the Rankine equation $\sigma_{max} = {}^1/_2\sigma + {}^1/_2\sqrt{\sigma^2 + 4\tau^2}$ are used, but this formula is losing ground in those countries and has been entirely abandoned in continental Europe.

On the other hand, the theory of shear stress developed on the basis of experiments carried out during the last 20 years starts from the viewpoint that it is the shear stresses in a body that cause various disturbances. The maximum possible shear stress is computed by the equation

$$\tau_{max} = {}^1/_2\sqrt{\sigma^2 + 4\tau^2} \qquad [3]$$

and τ_{max} with single axial loads is only half as great as the stress in tension. Numerous investigators, however, have vigorously questioned the correctness of this theory also, and in its stead several others have been proposed, of which the most important is the one suggested by Mohr in 1900.

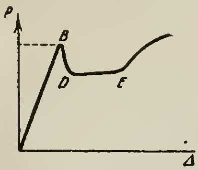

Fig. 1 Stress-Elongation Curve

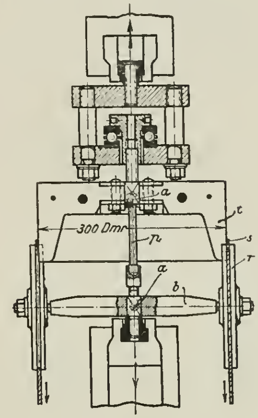
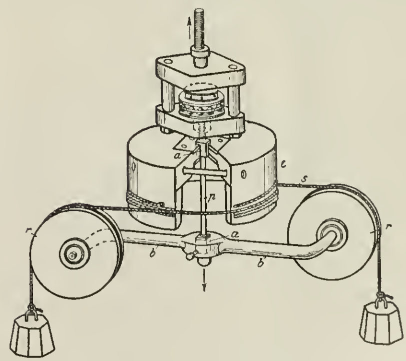
There are insuperable difficulties in the way of experimentally testing the correctness of any of the formulas proposed, as it is impossible at present to determine the stresses existing in the interior of a body. The only thing we can do is to measure the elongations and then compute the stresses that produce them on the assumption of proportionality in accordance with Hooke's law. This procedure, however, cannot be applied when we are dealing with combined stresses, because then single elongations cannot be measured any more, and, furthermore, Hooke's law does not apply for phenomena occurring beyond the elastic limit.

The following method may be applied in order to test the correctness of the various equations proposed for the determination of stresses.

The tension-elongation curve (Fig. 1) for soft iron, which is of importance in machine construction, runs as follows: After passing the limit of proportionality at the point B (upper yield point) where it reaches a maximum, it falls off down to the point D and then continues in a practically horizontal line. At E, however, the stress begins to rise again.

While, in general, the material does not indicate the stresses occurring therein, an exception to this rule occurs after the upper yield point B is passed, in that the scale beam of the testing machine suddenly drops, owing to the decreased resistance in the bar. If we start out with the assumption that a similar material independently of the method in which the stress is produced will suddenly give way at a predetermined stress, we can consider the dropping of the scale beam as an indication that through the coöperation of such tensional and torsional stresses as may be present the yield limit has been reached. If then we should compute the individual values of the tensional and torsional stresses according to the various formulas under consideration, that equation will prove to be entitled to greater consideration which under the various conditions of testing will give the same stress for the yield point at which the dropping of the beam takes





Figs. 2 and 3 Apparatus for Determining the Limit of Elongation in Test Bars

place. With this in view, the tests have been carried out on a testing machine with the auxiliary device illustrated in Figs. 2 and 3.

The test piece p is held at both ends in rectangular holders a. To the upper holder is attached a split wooden drum t, while the lower holder carries an S-shaped arm b with two rollers r (on ball bearings). The cord s transmits the torsional moment from the weights to the test piece p.

In the first instance Equations [1] and [3] of the theory of elongation and theory of shear, respectively, were tested and the data of these tests are presented in Figs. 4 to 7 where the moments of torsion are plotted as abscissae. These moments of torsion were obtained through a drum 30 cm. (1.18 in.) in diameter. The maximum torsional stress produced in the test piece and computed in accordance with the formula $\tau = 16M_d/\pi d^3$ is represented by an inclined straight line passing through the origin of coördinates. The tension stresses σ at which the scale beam drops down are plotted as ordinates. As was to be expected,

these stresses decreased with the increase in the moment of torsion.

The proper values of σ and τ were then computed and plotted first in accordance with Equation [1] (σ_i curves in Figs. 4 to 7) and then in accordance with Equation 3. The values τ_{max} were also plotted, since at $M_d = 0$, $\sigma = \sigma_i = 2\tau_{max}$.

Fig. 4 shows at a glance the superiority of Equation [1] as the values of σ_i remain approximately equal for all moments of torsion in clear distinction from the sharply rising curve of $2\tau_{max}$.

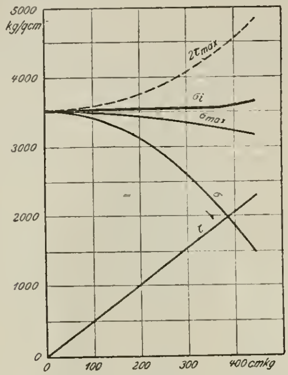


Fig. 4 Upper Yield Point in Solid Test Bars

In addition to tests for the upper yield point, tests were also carried out to the fracture point. Here the values of σ_i increase with increasing moments of torsion, though not in the same proportion as the values of $2\tau_{max}$. These tests, however, do not prove much, as the bar contracts laterally and the proportionality

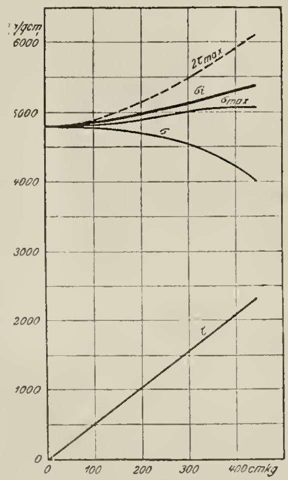

Fig. 5 Fracture Point in Solid Test Bars

between twist and torsional stress ceases to obtain. Because of this lateral contraction the diameter decreases, which affects the area carrying the stress in a square ratio, but the moment of resistance in a cubic ratio.

After the completion of the first series of tests with bars of commercial wrought iron 20 mm. in diameter and 100 mm. long, the question arose as to whether it is correct to compute the torsional stress even at the upper yield point under the assumption of the applicability of the law of proportionality, that is, whether it is correct to apply to the moment of resistance the formula $16M_d/\pi d^3$.

If it be assumed that the limit of proportionality is exceeded even before the occurrence of the dropping of the beam, it is necessary to admit that in the full cross-section of the test piece the torsional stresses do not occur in accordance with a straight-line law, increasing from the center of the piece outward, and therefore the moment of resistance cannot be computed. If, however, it be assumed that proportionality obtains down to the very instant of the dropping of the beam, the moment of resistance can be computed. In order to secure clearer information on this point, tests were carried out with hollow rods 12 mm. (0.47 in.) outside diameter and 8.17 mm. (0.32 in.) bore, the material for the test piece being taken from the same bar as the first test pieces. The tests carried out with the solid test pieces were repeated with the hollow test pieces (Figs. 6 and 7).

In this series of tests it was found that the dropping of the beam does not occur with the same clearness as in the case of solid bars, a fact which agrees with the behavior of machined material found by Bach.

In tensile tests on hollow test pieces all hesitation regarding the permissibility of making use of the moment of resistance is eliminated for the reason that in that case the entire material is located at approximately the same distance from the axis of torsion. This may explain why the σ_i values in the case of hollow test pieces barely vary with increasing moment of torsion, even in tests carried to the rupture point.

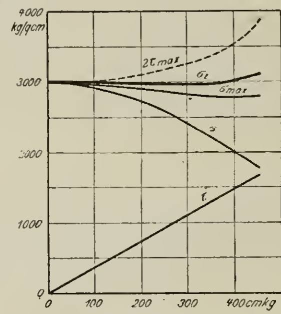

Fig. 6 Upper Yield Point in Hollow Test Bars

In this connection the author mentions the experiments of Guest, published in England in 1900, with the significant comment

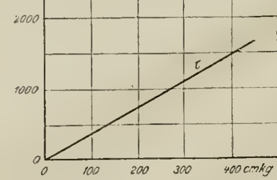

Fig. 7 Fracture Limit in Hollow Test Bars

that as Guest's values are expressed in English units, comparatively few German engineers would be inclined to devote time and attention to their study. Guest does not believe in the so-called theory of elongation. (*Zeitschrift des Vereines deutscher Ingenieure*, vol. 64, no. 51, Dec. 18, 1920, pp. 1071–1073, 7 figs., *pe*)

AERONAUTICS

Aeronautics in 1920 in Great Britain. A general review of events of the past year, of which the part referring to commercial aeronautics is of particular interest.

From an examination of results obtained on the mail service from London to Paris, it would appear that out of 391 flights 298 (76 per cent) were completed without a delay of more than three hours. In 16 cases the flights were completed during the day on which they were started, but without a delay of more than three hours. In 77 cases the flights were either completed on the following day, not completed at all, or not started.

Railway passengers would probably have just cause to complain if one train in every four on a certain line between two cities failed to make the trip with a delay less than three hours.

It has also been found that aerial transportation both of passengers and freight is still very costly as compared with other methods. The main reason, however, why the public distrusts aerial transportation is on account of the impression of danger.

Turning to the records of the past year in England it is found that during the seventeen months from May 1919 to September 1920, according to Air Ministry statistics, 100,285 passengers were carried in England in machines licensed for civilian flying. In this period seven pilots and eight passengers were killed in air accidents, and 13 pilots and 15 passengers were injured. The casualty rates per thousand passengers carried were thus 0.07 pilot and 0.08 passenger killed, and 0.13 pilot and 0.15 passenger injured. If the same rate of accidents prevailed on British railroads 140,000 passengers would be killed each year and over 260,000 injured, while in something like three months all the engine drivers in England would have lost their lives. Admitting that such a comparison may involve gross errors, the margin against the safety of flying is still quite great.

As regards the status of production, the Sopwith Company went into liquidation, the Aircraft Manufacturing Company was absorbed by another concern, while the British Nieuport, the General Aircraft Company, the Grahame-White and the British Aerial Transport Company have practically closed the doors. The Vickers, Ltd., has been doing some work on training machines and on an order from the Chinese Government. Several companies, however, are fairly active in developing new types. (*The Engineer*, vol. 131, no. 3393, Jan. 7, 1921, pp. 5–7, 3 figs., *g*)

AIR MACHINERY (See also Machine Shop; Wind Motors)

Scholl Automatic Hydraulically Operated Air Pump. The purpose of the air pump described in this article is to create automatically a vacuum in centrifugal pumps, suction lines and vacuum apparatus generally, and also to create a pressure in air chambers on pumps, air lifts, etc. Fig. 1 shows the principle on which the Scholl pump is designed. Assume that the container *a*, the riser pipe *g* and the ground pipe *r* are filled with liquid and that further the float and water valves are in positions shown in the drawing, so that gas at atmospheric pressure can be drawn in by suction. Since the outlet of pipe *r* is below the level of *a*, the liquid in *b* will flow out through *r* and force the gas through *k* by suction into the container, while the level of the liquid in the float goes down and the float itself rises. Sooner or later the upward movement of the float overcomes the pressure in the water inlet valve *i*, the valve rises and takes the open position while the exhaust valve *f* closes. The liquid flowing in through *i* passes through the channel *w* into the ring-shaped space between *a* and *b*, where because of the rise of the float the lever of the liquid has gone down thus it passes into the interior of the float. Simultaneously with this, however, the gas content in *a* is compressed and when it reaches the necessary gage pressure is delivered through *l* into the pressure line connected thereto. Shortly before the float is entirely filled with liquid the weight of the float overcomes the pressure difference between *a* runs out through *f* and *g* and the gas taken in by suction is again in position to flow into *a* through *k*, which starts the new cycle of operation similar to the one described above.

With the arrangement shown in Fig. 1 the gas is delivered to the pump through a suction line attached at *k* and passed along through *l*. The pressure liquid from the air pump is discharged at *r* of which the lower end should be bent upward to prevent the entrance of air. If the pressure of the gas taken in by suction is equal to or lower than atmospheric pressure, the lower end of *r* must be located lower than the pump, its position being determined by the specific weight of the liquid and the vacuum obtained.

With a pump of ordinary design in operating single-stage a vacuum in the ratio of ten to one or 0.1 atmosphere absolute can be obtained; in compression the gage pressure of 10 atmos. can be obtained. Where pressures higher than 10 atmos. are desired, a special high-pressure model must be employed.

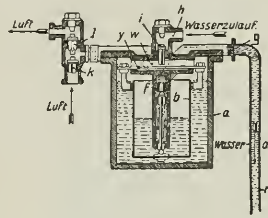

Fig. 1 Scholl Automatic Hydraulically Operated Air Pump
(*Luft* = air; *wasserzulauf* = water admission; *wasserablauf* = water outlet.)

Several other designs of the same pump applicable to various purposes are described and illustrated. (*Der Praktische Maschinen-Konstrukteur*, vol. 53, no. 43, Oct. 28, 1920, pp. 380–382, 6 figs., *d*)

BUREAU OF STANDARDS

Gypsum—Properties, Definitions and Uses. Owing to the rapid growth of the gypsum industry, the nomenclature has not been standardized. A brief description of the various gypsum products will tend to fix their names.

Gypsum is a soft, white rock, usually occurring in beds. Other varieties of the same material are known as gypsite and alabaster. It is of common occurrence throughout the United States. Chemically it is a calcium sulphate combined with water. Anhydrite is a variety which contains no water.

Raw gypsum is used for the manufacture of portland cement and as a fertilizer. Calcined gypsum is made by heating raw gypsum in a kettle until the first evolution of water has ceased. It contains one-fourth as much water as the raw material. This product is frequently known as plaster of paris and is used either as such or as the basic ingredient for the manufacture of wall plaster, potter's plaster, dental plaster, etc. Large quantities of it are used in the manufacture of portland cement, plate glass, and cold-water paints.

When calcined gypsum is mixed with water it sets to form a hard mass. The time required for this reaction can be varied at will by the addition of suitable retarders or accelerators.

Neat gypsum plaster is calcined gypsum to which has been added some material (such as hydrated lime) to improve its working quality, and the proper amount of retarder. Gypsum sanded plasters are mixed with sand ready for use. Any of these plasters may or may not be "fibered" with either hair or wool fiber. And a special wood-fibered gypsum plaster is made to be used without sand.

Gypsum plasters have excellent fire-resistive ability.

The raw gypsum can be heated until all of the water is given off. The product so formed sets more quickly than calcined gypsum. It is not marketed, but is used at the factory to make such

products as gypsum tile, gypsum plaster board, gypsum wall board, etc. Further heating of the raw gypsum forms a material which sets very slowly. An accelerated variety of this is marketed as Keene's cement.

Gypsum tiles are factory-made building blocks. They come in a great variety of sizes, either plain or reinforced. They are used for building walls and roofs.

Gypsum plaster board consists usually of a sheet of set gypsum plaster between two sheets of unsized paper. It comes in many sizes, usually about 3 ft. sq. by $^3/_8$ in. thick. It is used instead of lath as a backing for plaster.

ENGINEERING MATERIALS (See Bureau of Standards)

FUELS AND FIRING

Modern Gasoline and Its Vaporization—Heated Manifolds and the "Hot Spot"

The Volatility of Internal-Combustion Engine Gasoline, Frank A. Howard. Discussion of the character of gasoline, its vaporization, and available means for improving combustion. The author sees the best solution of the present problem in a wider adoption and improvement of heated manifolds, in particular of the hot spot. Particular attention is called to data presented on the vapor pressure and inherent volatility of the gasoline of today.

Gasoline is a complex mixture of hydrocarbons, varying from pentane, the lightest, to undecane, the heaviest present. From the chemical equations of volumetric proportions of a combustible mixture it is found that a perfect combustible mixture of pentane vapor and air must consist of 40 parts by volume of air and 1 part by volume of pentane. Also a perfect combustible mixture of undecane vapor and air must consist of 1 part of the fuel to 85 parts of air, by volume. Since gasoline contains more of the lighter than of the heavier hydrocarbons, the volumetric proportion of gasoline vapor in a perfect mixture will be somewhere in the neighborhood of 1 part in 60, or 1.67 per cent.

Such a small proportion of gasoline vapor in the mixture can be brought about by evaporating the gasoline under favorable conditions and without boiling it. Dalton's laws of the vaporization of liquids state that evaporation from an exposed liquid continues until there is established a definite pressure of the vapors of the liquid, that this pressure increases with the temperature, and that when other vapors are present the total pressure of the mixture multiplied by the volumetric percentage of any constituent gives what is called the partial pressure of that constituent; so long as the partial pressure of the vapor in question is below the vapor pressure of the liquid, condensation cannot occur.

Measurements of the vapor pressure of 58 deg. Baumé gasoline in air were made with an instrument designed by C. I. Robinson, chief chemist of the Standard Oil Co. of New Jersey. First the vapor tension of the original gasoline was determined at several temperatures. Then the sample was reduced by distillation in the ordinary way, taking off successive 10 per cent fractions. After each reduction operation the vapor tension of the residual portion of the gasoline was determined at temperatures of 50, 75, 100 and 125 deg. The vapor tension in millimeters of mercury was 44.75 at 50 deg. fahr. with 90 per cent residuum, 9.66 with 60 per cent, and 4.84 with 40 per cent. At 125 deg. fahr. with 50 per cent residuum the tension was 29.50; with 30 per cent, 12.55; with 20 per cent, 8.05; and with 10 per cent, 5.07. Of the last residuum, according to the combustion equation, a perfect combustible mixture would contain 1.2 per cent. The average pressure in an engine manifold is around 0.5 atmosphere. Calling it 400 mm. of mercury, $0.012 \times 400 = 4.8$ mm. is by Dalton's law the partial pressure of the fuel vapor, assuming that the fuel is made up entirely of the least volatile fraction of the present gasoline. But, as the figures quoted indicate, at any temperature above 125 deg. fahr. the least volatile portion of the gasoline had a vapor pressure well above 4.8 mm. It follows, therefore, that even if the gasoline consisted entirely of what is at present its heaviest constituent, it would still possess sufficient inherent volatility to make it a possible fuel for an automotive engine. It is a fuel and can become and must remain a gas at an intake temperature not substantially higher than present practice. Stating it generally, complete vaporization of fuels heavier than those now sold is possible without increase of mixture temperatures; but condensation of these fuels is impossible. Manifold condensation is impossible above the temperature indicated, because it is physically impossible for any vapor to condense when its partial pressure is lower than the determined vapor pressure of the liquid itself at that temperature, and this is apparently the average condition in an engine manifold.

Utilization of the full inherent volatility of a fuel is dependent upon three factors: time, surface and heat. If heat is applied rapidly enough and at a high enough temperature, surface and time become unimportant.

Air heating and manifold heating are helpful, but apparently the means which best meets the physical requirements of volatilization is the so-called "hot spot." The definite problem is to supply heat to the fuel; not to supply heat to the air or to the mixture, but to the fuel itself. This heat should be supplied to the fuel in the presence of the air to have its maximum effect. Preheating the fuel would cause the distillation of the lighter hydrocarbons and their consequent wasteful loss. The latent heat of vaporization of the fuel must be applied to it as (or after) the mixture is made. One obvious way is to preheat the air; another, to directly heat the charge. However, the heat conductivity of air is so low that, unless this is carried to an extreme which results in substantial loss of power, there is not sufficient time for the necessary exchange of heat between the evaporating fuel drop or film and the enveloping air current.

The solution of the problem, therefore, seems to lie in the further development of the hot spot. Tests have been reported in the technical press which showed that within 35 sec. after the exhaust gases were admitted to the jacket of the hot spot the mixture passing was perfectly dry as shown by a glass manifold. The writer found in experiments with a hot spot of that design that complete vaporization of the fuel was secured with a manifold temperature beyond the hot spot of 125 deg. fahr. The surface of the hot spot itself showed a temperature of 350 deg. fahr., as accurately as could be measured. It is apparent that advanced hot-spot design has already reached a point at which automotive engineers can come very close to utilizing the full inherent volatility of the fuel by the simple and logical expedient of directly heating the unvaporized fuel in contact with the air, rather than by trying to preheat the fuel or to heat the fuel by contact with heated air. (Paper read at the Annual Meeting of the Society of Automotive Engineers, New York City, January 12 and 13, 1921, 4 pp., 1 fig., *tep*)

Importance of Hardness of Blast-Furnace Coke, Owen R. Rice. Coke to be used in blast furnaces has to be of a certain hardness because soft coke does not permit proper furnace operation. The methods thus far employed to determine the physical nature of coke have not, however, given full satisfaction.

Thus the shatter test does not fully indicate the character of coke and the author recommends instead an apparatus which has a combination of a tumbler and ball mill.

On the other hand, however, it should not be thought that the hardness of coke is the deciding element in furnace operation, though it has been found that coke of the hardness below number 81 causes trouble, while the hardness above 85 does not appear to bring any particular advantage.

There does not appear to be any clearly established rule determining the quality of coke resulting from different coals. Ash in coke has a detrimental effect on hardness. Another factor which affects the coal materially is the hydrogen-oxygen ratio. The stocking of coal affects this ratio in a very material manner. A 9-mo. stock of Davis coal showed a ratio of 102 per cent, while Davis coal direct from the mine showed a ratio of 125.8 per cent. Some 9-mo. stock of Fulton coal showed a ratio of 55.1 per cent, while Fulton coal direct from the mine showed a ratio of 57.5 per cent. (Paper presented at the Annual Meeting of the American Inst. of Mining and Metallurgical Engrs., New York, Feb. 1921, abstracted through the *Iron Age*, vol. 107, No. 6, Feb. 10, 1921, pp. 380–381, 1 fig. *ep*)

of Highly Volatile Fuel Without Intervening Cleaning, A. B. Reck. Results of two tests with bituminous coal—one made before and another after 14 days of continuous firing with the same fuel without intervening cleaning. The test results are given in the form of a table and curve, the former showing that the overall efficiency obtained in the test with clean boilers was 77.9 per cent and was lowered to 74.9 per cent, or only 3 per cent after 14 days of continuous running.

This relation between efficiency, capacity and chimney draft is shown graphically in the diagram in Fig. 2, together with similar results obtained in a great many other tests made with the same kind of fuel, viz., bituminous coal, and in the same clean boiler. The curve shows a maximum efficiency around the capacity, at which the test A was conducted. As neither the capacity nor the efficiency is seriously reduced after 14 days of continuous firing at approximately the same draft (see test B), the conclusion may be drawn that with sufficient data at hand of tests made with the same fuel and the same boiler after 14 days of continuous firing it should be possible to draw a new efficiency curve, in which the efficiency found in test B likewise will prove to be a maximum.

In order to verify the correctness of efficiency values with clean boiler and bituminous coal, tests were made in the same type of boiler with anthracite of stove size. The efficiency obtained with

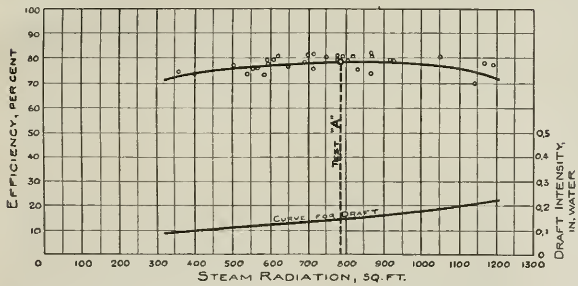

Fig. 2 Efficiency Curve for Steam Boiler with Bituminous Coal (Clean Boiler)

that fuel was 83.1 per cent, or 5.2 per cent higher than with bituminous coal.

The author ascribes these high efficiencies to the method employed in introducing the supplementary secondary air. Each section of the boiler is provided with an air channel located on the edge toward the combustion chamber as shown in Fig. 3. The air leaves the canals through the opposite rows of close-sitting openings in the form of jets, striking the combustible gases liberated from the surface of the fuel bed just as they are to enter the smoke flues, which are located between the boiler sections. It is claimed that this intermixing shower of fresh air evenly distributed over the whole surface of the fuel bed is sufficiently far from the surface itself to avoid acting as primary air. It is also claimed that the use of these air channels prevents the overheating of the exposed water ways, acting for them as a protection against the radiant heat. HEATING (See Fuels and Firing)

HYDRAULIC MACHINERY (See Air Machinery)

INTERNAL-COMBUSTION ENGINEERING (See also Fuels and Firing; and the Abstract on page 192)

Air-Temperature Regulation Effects on Fuel Economy, Reuben E. Fielder. Test conducted by Fifth Avenue Coach Co., of New York City, to study the effect on fuel economy of regulating the temperature of the air entering into the engine cylinders. Comparative tests were made with and without this thermostatic-control device, using the same engine, carburetor and similar equipment, under the same atmospheric temperature conditions. The average saving in fuel consumption was 7.85 per cent and a 5 per cent increase in horsepower was obtained when using the thermostatic control.

The temperature in the manifold when using the thermostatic control was constant, whereas without this device it varied from 130 deg. fahr., as a minimum, to 160 deg. fahr., which showed a loss of power and increased consumption of fuel at all speeds, indicating a loss in volumetric efficiency due to excessive heat. This test was made at a time when the atmospheric temperature was 68 deg. fahr. What happens when the atmospheric temperature is around 90 deg. fahr. as in the summer, or 0 deg. fahr. as in winter, can well be imagined.

The best manifold temperature for the gasoline used was found to be 102 deg. fahr. This temperature was determined upon after tests in which the engine speed was held constant while varying the temperature in the manifold, the power developed

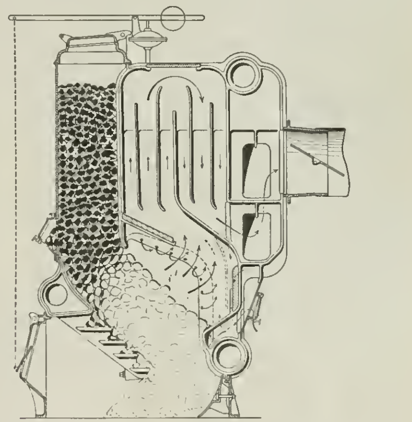

Fig. 3 Vertical Section through Reck Boiler

and the fuel consumption being recorded. The speeds selected were 700 and 1200 r.p.m., thus representing the high and low limits of speed. With the thermostat set to maintain a manifold temperature of 102 deg. fahr the saving in fuel was 8 per cent or more.

Other tests were performed to observe the effect of variation of manifold temperature on economy and torque, with different jets, and also the effect of thermostatic control on the volumetric efficiency of the engine. (Paper read at the Annual Meeting of the Society of Automotive Engineers, New York City, January 11–13, 1921, 4 pp., 7 figs., *c*)

Problems Awaiting Solution in Diesel-Engine Design

Problems and Probable Field of the Oil Engine, Paul Rieppel. The author starts with the discussion of the economical and political problems connected with the control of the world's supplies of oil and of the application of the oil engine—by which he means the various types of internal-combustion engines, the Diesel and its modifications being first considered. In the course of the article the author makes many interesting observations and raises several questions well worth attention.

Combustion Processes. As regards the nature of combustion processes in the Diesel engine, our knowledge has reached the point where we can clearly distinguish the processes of injection, vaporization, gas formation and combustion. The author believes, however, that a very wide field in this domain remains as yet unexplored and that more work should be done in the laboratory by the physicist, such work being preferable in many cases to extensive experimentation on actual engines.

The most rapid and complete combustion is a function of the fineness of atomization, intermixture with air, and, to an extent which has not yet been fully appreciated, of turbulence. No thorough tests have been made to determine what is the best method to obtain the most complete atomization and what fineness of atomization is needed under each set of conditions.

As to the influence of catalysis in the cylinder, whether that due to presence of water or of some other catalytically acting material, the tests of Stein contain valuable material, but the influence of very small, in fact extremely small, amounts of water on fuel combustion remains as yet to be investigated. As a matter of fact we know that under certain conditions very poor oils burn better in the presence of water, and the use of other catalytic agents, such as silicon and various metals, may bring startling developments in engine design and offer a means of increasing our ability to control combustion.

How to obtain the best possible conditions of turbulence and how to evaluate the influence of turbulence are questions which may be answered by tests on self-ignition of oils and the velocity of flame propagation therein. In a bomb, oil vapor at rest does not ignite at all at temperatures corresponding to the temperature of compression in a Diesel engine, but when a slight turbulence is produced, as, for example, by injecting a small amount of air, self-ignition takes place. Comparatively little has been done in this direction. This and other questions must be considered by everyone interested in the subject of combustion processes, and they are not mere academic problems but important stones in the foundation upon which the structure of economic design of an engine has to be raised. Had we had this information a highly economic Diesel engine could have been designed long ago and have done away with the compressor. From this the author proceeds to the discussion of various attempts to build a Diesel engine without a compressor, such as have been proposed by Vickers, Price and Steinbecker.

Economy of Operation. In the determination of the economy of operation, questions as to the use of a 4-stroke or 2-stroke cycle, high or medium pressures, are ones which lie at the foundation of the problem. After discussing briefly the relative position of the 4- and 2-stroke cycles and the question of scavenging, the author proceeds to the question of compression and asks whether we shall continue to operate Diesel engines with a compression of 35 atmos. and the heavy weight of the engine and mechanical difficulties which it involves.

The higher thermal efficiency secured with this compression does not have decisive value in the author's eyes, as motors employing lower compression pressures would have a lower first cost, be more reliable and show a better mechanical efficiency. As regards the advantage secured through self-ignition of the mixture, it is pointed out that the point of self-ignition is lowered very materially when the cooling produced by the expanding stream of the injection air is eliminated. With solid injection every condition of engine operation can be met without external means of ignition at a pressure of 25 atmos. But even assuming that self-ignition would have to be dispensed with, why not? The high value placed on the ability of the engine to operate on a basis of self-ignition is a survival of a time when electrical ignition was still complicated and unreliable. Today it is quite easy to provide reliable means of producing a good electric spark having a good control of timing, or, where necessary, to produce a wire spirally wound and maintained constantly at a glowing heat by a flow of electric current. There is no reason why one should not employ outside methods of ignition in engines in which the most economical operation may be secured at compressions at which self-ignition can no longer be relied upon.

In connection with the problem of securing the most economical operation of oil engines, the author takes up the question of utilization of waste heat. It is true that as high as 40 per cent of the heat in the fuel may be usefully employed in the oil engine, but this is no reason why one should waste the other 60 per cent without any effort at recovery. The comparison with the 12 per cent heat efficiency of the steam engine is often misleading because in a steam engine a good deal of the heat in the exhaust steam may be still utilized for purposes of heating and drying. In properly conducted factory processes employing steam, the power generated by the steam engine should be considered as a mere by-product, while in the case of oil-engine drive it is the main if not the only product of fuel combustion.

The problem of utilizing the waste heat of oil engines is one of the most important from an economical point of view. The usual way is to pass the exhaust gases on to steam boilers, a method well known in large gas-engine operation. This cannot be done as conveniently with oil engines, because the temperature of the exhaust gases is considerably lower. Furthermore, any attempt at a thorough utilization of exhaust heat from oil engines would involve a considerable increase in the first cost of the installation and also possibly corrosion troubles due to the presence of sulphurous acid in the exhaust gases. In particular, in the case of auxiliary boilers on shipboard, it has been found advisable to equip them with direct oil heating in addition to heating by exhaust gases. An important physical problem is the determination of the coefficient of heat transfer from exhaust gases to the boiler wall. This is a question proposed by Nusselt, but, in general, the coefficients now employed are more or less of a rough nature and do not take into consideration many important factors.

In this connection may be mentioned attempts to mix the exhaust gases with steam and to add to them compressed air and utilize the mixture either in turbines or in reciprocating engines. It does not appear than any such efforts may lead to useful conclusions.

In another part of the same article, which will be abstracted at an early date, the author discusses the application of oil engines, in particular those operating on heavy oils as opposed to gasoline and kerosene engines, to various specific purposes, such as the driving of locomotives, road vehicles, tractors and aircraft. (*Zeitschrift des Vereines deutscher Ingenieure*, vol. 64, nos. 49 and 50, Dec. 4 and 11, 1920, pp. 1021–1027 and 1051–1055, 10 figs., *gA*)

MACHINE SHOP

Sand Blasting, C. W. Starker. A practical article describing the types of apparatus, abrasives, nozzles, air pressures, dust exhausting and general methods of operating.

There are several systems of sand blasting differing in the manner of applying the stream of abrasive to the surface to be treated. Air compressed to varying pressures is commonly employed in all sand-blasting equipment, but the pressure is applied in different ways.

In the direct-pressure system the air and the abrasive are combined in and discharged from a closed tank through a nozzle. In the suction system the abrasive is carried to the nozzle by the suction created by a jet of compressed air, which, in passing through the nozzle, carries the abrasive with it. This system is also known as the siphon system. For this system an apparatus known as the sand-blast gun is employed. In the third system, known as the gravity system, the abrasive is carried by mechanical means to a place above the nozzle and is fed down by gravity.

In general it may be said, other things being equal, that the higher the air pressure used the stronger the force of the jet discharged against the surface to be treated, and therefore the greater the amount of work done. It may be roughly stated that according to actual practice 50 lb. air pressure will perform twice as much work as 20 lb., or 65 lb. will accomplish twice as much as 30 lb., and 72 lb. twice as much as 40 lb. The air pressures used for different materials are as follows (fair average practice): Steel castings or forgings, 80 to 100 lb.; malleable iron, 70 to 85 lb.; cast iron, 60 to 70 lb.; and brass and aluminum, 35 to 50 lb.

The volume of air flowing to a nozzle opening at a given pressure is governed by the size of the nozzle. (Table 1). As the nozzle is apt to wear, however, it is important to design it so as to reduce this wear as much as possible. Moisture in compressed air prevents an even flow of abrasive and causes the sand to form lumps. It is also detrimental to pneumatic tools which are operated from the compressed-air system.

As regards the abrasive materials, sand is the most commonly used on account of its relatively low price. Ordinary lake or river sand is inferior to sea sand and silica sand. Abrasives, such as steel grit and shot are used to a certain extent, but are not suitable

All abrasives should be screened each time before using to remove particles large enough to plug the nozzle and also to eliminate fine particles which only produce dust and have no abrasive quality.

TABLE 1 FLOW OF FREE AIR FOR DIFFERENT SIZES OF NOZZLES

Diameter of nozzle, in.	Pressure (Cu. Ft. per Min.) and Corresponding Horsepower Required							
	20 Lb.	Hp.	30 Lb.	Hp.	40 Lb.	Hp.	50 Lb.	Hp.
1/8	7.70	0.63	10.00	1.03	12.30	1.50	14.50	1.99
3/16	17.10	1.40	22.50	2.32	27.50	3.26	32.80	4.49
1/4	30.80	2.53	40.00	4.12	49.10	5.99	58.20	7.97
5/16	48.17	3.95	62.89	6.48	76.60	9.36	90.70	12.43
3/8	69.00	5.66	90.00	9.27	110.00	13.42	130.00	17.81
	60 Lb.	Hp.	70 Lb.	Hp.	80 Lb.	Hp.	100 Lb.	Hp.
1/8	16.80	2.57	19.00	3.19	21.20	3.86	25.73	5.33
3/16	37.50	5.74	43.00	7.22	47.50	8.65	57.88	11.98
1/4	67.00	10.25	76.00	12.77	85.00	15.47	103.00	21.32
5/16	105.00	16.07	119.00	20.00	133.00	24.10	161.00	33.82
3/8	151.00	23.10	171.00	28.73	191.00	34.76	232.00	47.90

It is important to have the sand-blast rooms well ventilated. In the majority of cases it is also necessary to provide methods for gathering and settling the dust rather than discharging it into the atmosphere. (*Machinery*, vol. 27, no. 5, Jan. 1921, pp. 458–462, 11 figs., *p*)

Work Speeds in Cylindrical Grinding, Robert J. Spence. The author claims that the importance of the function of the speed-changing device in grinding machines does not seem to be understood in general by the operators, of whom a very large number believe that the faster the work revolves the greater the amount of work produced. The author believes this is erroneous and that to operate a grinding machine continually on the fastest work speed is just as wrong and just as wasteful as it would be for a lathe operator to run his machine continuously at a filing speed when turning work.

To prove this, the author analyzes a case where a man is grinding a bar of steel and using the fastest work speed and fastest table traverse with which the machine is equipped. He shows that when an excessively high speed is used only part of the wheel face is presented to the work, and when such a thing happens the remaining part simply laps over on the surface ground during the preceding revolution of the work and there is a non-uniform wearing action. The portion of the wheel face which is not cutting but simply dragging on the work becomes glazed and adds useless friction to the operation, thus increasing the power consumption of the machine.

The importance of using the greatest possible radial depth of cut is next discussed. Even a small increase in the radial depth of cut permits for the same amount of work to reduce the number of table traverses, which, for the same rate of traverse, means a material reduction in the time consumed in grinding a piece.

The question of the effect on the amount of stock removed in its relation to wheel wear when the speed of grinding is reduced, is also discussed in some detail on the basis of the graphic analysis of the action of a grinding wheel proposed by Prof. George I. Alden. A discussion of the numerical case indicates that in that instance a change of work speed from an excessive rate of 190 r.p.m. to a more rational speed of 75 r.p.m. increases the amount of stock removed per unit of wheel wear 150 per cent. (*Machinery*, vol. 27, no. 5, Jan. 1921, pp. 438–440, *p*)

MEASURING INSTRUMENTS

Use of the MacMichael Viscosimeter in Testing Petroleum Products, W. H. Herschel and E. W. Dean. The MacMichael viscosimeter is of the torsion type. Its essential parts are a rotatable motor-driven oil cup and a torsional pendulum suspended above the center of the cup by a piano wire. The cup has an inside diameter of about 70 mm. (2–13/16 in.), is equipped with an external heating coil of resistance wire (which can be used only when the cup is at rest), and is set in an oil jacket which also revolves. The cup is driven with a set of speed-reducing gears by means of a small electric motor. The latter is equipped with a speed-control device of the phonograph type and it is possible

The pendulum consists of a tube inclosing the suspension wire and carrying a disk at its lower end, an oil-filled dashpot slightly below the middle of the tube, and a graduated dial near the point of support. The disk is about 60 mm. (3–5/16 in.) in diameter and 5 mm. (3/16 in.) thick. The dashpot, attached to a support cast on the frame of the instrument, serves to minimize oscillation of the pendulum and also is a convenient device to indicate when the whole instrument is properly leveled.

The dial is fastened to the tube by a tapered fit and is graduated from 0 to 300 for reading the angular deflection of the pendulum. The zero setting is made roughly by turning the dial on the tube, and more accurately by movement of the pointer attached to the support of the pendulum.

The instrument may have wires of different sizes.

Some of the limitations of the instrument are indicated by this description. It is obvious that one of the most vital parts is the suspension wire and that this can easily be injured either through careless handling or by using a wire with so viscous an oil that the deflection is sufficient to strain the wire. One of the vital dimensions controlling the readings obtained is the clearance between the bottom of the disk and the oil cup. The method of attaching the wire in the disk is such that it is practically impossible to control this clearance, which is a disadvantage in that it renders a new calibration necessary every time a wire is removed and replaced. Changing of wires is frequently necessary, as one of the principal disadvantages of the instrument is the range of viscosity that can be covered by the use of properly selected wires of different diameters.

The advantages of the MacMichael viscosimeter as compared with the usual efflux types are (1) that the time consumed in making a determination with it is relatively small, and (2) that it gives moderately accurate results with oils that are not perfectly homogeneous. This latter is important in measuring the apparent viscosities of such substances as emulsified products or used automobile crankcase oils containing both water and finely divided sediment. Efflux type viscosimeters (such as Saybolt) are extremely unreliable for testing products of this sort, while with the MacMichael instrument reasonably accurate measurements can be made. It is also of value in distinguishing true liquids from plastic solids.

The limitation, in addition to what is stated above, lies in the fact that its construction is such that calibration of the instrument in terms of its dimensions is impracticable.

It is important to bear in mind that the readings of the MacMichael viscosimeter are related to absolute viscosity instead of kinematic viscosity, and it is therefore necessary to know the specific gravity of the oil tested before MacMichael readings can be translated into terms of Saybolt seconds. This, however, introduces no difficulty as it is the practice in the petroleum industry to measure the gravity of all samples anyway.

The paper gives careful directions for the calibration of the apparatus and for the methods of its use. Among other things, an interesting method is suggested for measuring absolute viscosities with the Saybolt viscosimeter. (Reports of Investigations of the U. S. Bureau of Mines, Serial No. 2201, Jan. 1921, abstracted from mimeographed copy, *tp*).

MECHANICS

Torsional Strength of Multiple-Splined Shafts, C. W. Spicer. Comparative torsional tests of splined shafts and full-round shafts.

Fifteen shafts were tested. Five were splined with small diameter of 1.315 in. and outside diameter of 1.5874 in. The other ten were full-round shafts, five 1.2806 in. in diameter and five 1.5 in. in diameter. This last diameter was computed as the theoretical equivalent of the splined shafts. The 1.2806-in. shafts were intended to have the same diameter as the small diameter of the splined shafts, but they were reduced to the size that would clean up by grinding the most badly warped shaft in the

heat-treating operation. All of the full-round shafts had at the ends practically the same diameter as the large diameter of the splined shafts.

Curves were plotted showing twist against torsional stresses. An Olsen torsion-testing machine was employed and readings were taken by means of the Olsen troptometer attachment. The average readings obtained with the five shafts of each series were used.

It was found that a twist of 0.2 in. measured on a 12-in. radius between 9-in. centers was produced in the full-round shafts with the small diameter by a load of 6000 lb. per sq. in., while 8350 lb. per sq. in. was required to produce the same twist in the splined shafts and 11,500 lb. per sq. in. in the theoretically equivalent full-round shafts. For a twist of 0.3 in. the figures were 9000, 12,250 and 17,000 lb. per sq. in., respectively, for each of the three classes of shafts. Similarly for 0.4 in. twist, 12,000, 16,500 and 22,500 lb. per sq. in.; and for 0.5 in. twist, 15,000, 20,000 and 27,800 lb. per sq. in. At this point the Johnson elastic limit was located for the splined shafts, that is, the unit increment of deflection per unit load increase was 50 per cent greater than at the beginning. The Johnson limit occurred in the small round shafts at a load of 22,000 lb. per sq. in. with a twist of 0 78 in., and at 32,000 lb. per sq. in. with 0.58 in. twist in the theoretically equivalent round shafts. (Paper read at the Annual Meeting of the Society of Automotive Engineers, New York City, January 12 and 13, 1921, 2 pp., 4 figs., *e*)

Three-Point Suspension for Automobile Engines, One Point Being Rigidly Fixed

A New Principle of Engine Suspension, S. E. Slocum. Discussion of application of three-point system of support to automotive engines as a means for eliminating the vibration due to synchronism.

In designing a system of engine suspension which will eliminate vibrations, it is well to remember that there are two main types of vibration, one due to unbalance and the other to synchronism.

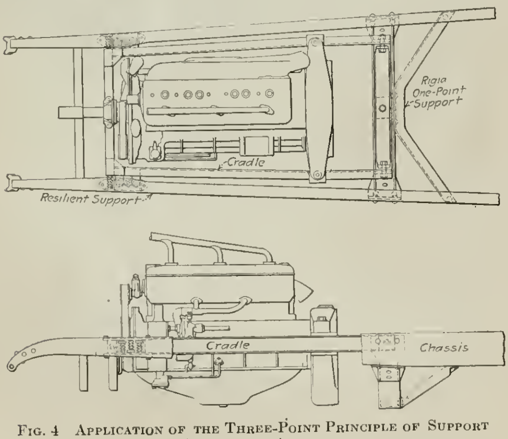

Fig. 4 Application of the Three-Point Principle of Support to Automotive Apparatus

The first can be eliminated by well-known methods of balancing, leaving only the vibration due to torque recoil and inertia forces. The second can be eliminated by preventing synchronism, and this can be accomplished by isolating a machine from its support so far as the transmission of vibrations is concerned. To explain what this implies, it is pointed out first that any body may have at most six degrees of freedom; that is, it may be free to move along any three mutually perpendicular axes, giving three degrees of freedom, and it may also be free to rotate about these three axes, giving the remaining three degrees of freedom. If one point of the body is fixed, this destroys the first three degrees of freedom since the body can no longer move as a whole in any direction; but it is still free to rotate about any axis through the fixed point, so that it still possesses three degrees of freedom as regards rotation.

To apply this to the automotive engine, suppose that one point of the engine is fixed, so that it can pivot about this point. Suppose that, in addition to this one fixed point, two other points of the machine are mounted on resilient supports. It is then evident not only that the machine will have three-point support, but also that within certain limits it will have freedom of motion about the fixed point, due to the resiliency of the other two supports. This type of three-point support, one point being rigidly fixed and the other two supports being elastic or resilient, leaves the body three degrees of freedom, and yet makes it possible to control absolutely the period of the vibration. In other words, by properly designing or adjusting these resilient supports it is possible to change the period of vibration so as to prevent any possibility of its synchronizing with the natural period of the engine bed or foundation.

Fig. 4 illustrates a three-point-support system as applied to automotive engines. The method consists in mounting the engine in a cradle, and supporting this cradle on the chassis at three points. The rear support is here the rigid point of the three, and in this case is placed directly underneath the transmission. The two forward supports are the resilient ones and are formed by interposing coiled springs between the cradle and the chassis. A special form of double telescoping spring is used, which permits vibrations of very small amplitude, but is very rigid as regards road shocks. In fact, the action of the resilient supports is exactly the opposite of the ordinary shock absorber. The supports absorb vibration but do not respond to road shocks.

It should be noted that this method of suspension supplements, but does not replace, careful balancing of all rotating parts; furthermore, that its use will improve the performance of any type of engine, although most needed by the four- and eight-cylinder types. (*The Journal of the Society of Automotive Engineers*, vol. 8, no. 1, Jan., 1921, pp. 54–56, 1 fig., *tp*)

MOTOR-CAR ENGINEERING (See also Mechanics)

POWER GENERATION (See also Wind Motors)

Power Generation from Natural Hot Waters

Power Generation from Natural Hot Waters, P. Caufourier. In a number of places in France, northern Africa, Syria, Martinique, New Caledonia, etc., there are natural sources of hot water, and attention has been drawn to them as a possible source of power generation through the rise of cost of fuel in the last few years.

The idea itself is not new, and several attempts have been made to employ such water for useful purposes. In 1917 Gabrié presented to the Academy of Sciences in Paris a proposal to vaporize water by means of heat in the interior of the globe, believing that the depth to which the water would have to be delivered would not be prohibitive.

In the present instance, however, the discussion is confined to the use for purposes of power generation of hot water as it comes out of the ground without adding any heat through external combustion. This is intended to be done by means of "self-evaporation" of natural hot water. The theory of this is as follows: Let there be a weight P of water at the temperature t_0 enclosed in an adiabatic chamber under an absolute pressure below the saturation pressure of steam at t_0. The liquid will then evaporate partially up to the point of saturation of the free space, and in doing so will borrow the latent heat of evaporation from the non-evaporated part of the liquid. Let t_1 be the final temperature and p the weight of the vaporized liquid. We then have the equation

$$P(t_0 - t_1) = p(606.5 - 0.695t_1)$$

A drop in temperature of 6 deg. cent. will vaporize about 1 per cent of water (by weight). If now the vaporizer be placed in communication through a turbine with a condenser of temperature t_2, saturation will no longer occur and steam generation will be continuous. The output of steam will be a constant one on condition

densing, the steam will give up a quantity of heat equal to

$$p(606.5 + 0.305\, t_1 - t_2)$$

and the work which can be theoretically usefully employed is represented by the product obtained by multiplying this quantity by the mechanical equivalent of heat (425) and by the Carnot efficiency coefficient $(t_1 - t_2)/(273 + t_1)$, all values being in c.g.s. units.

The application of this method of computation to various values of t_1 and of $t_0 - t_1$ when t_2 = 27 deg. cent. gives the results shown in Table 2, where for each of the three temperature differences the first line represents the water vaporized by the cooling of a cubic meter of water from t_0 to t_1, and the second line represents the corresponding output of power (theoretical) in metric horse-

TABLE 2 WATER VAPORIZED AND POWER GENERATED IN A LOW-TEMPERATURE SELF-VAPORIZING BOILER

	Values of t_1					
	45 deg.	54 deg.	63 deg.	72 deg.	81 deg.	90 deg.

power-hours. For practical purposes the values in the table for the theoretical horsepower per cubic meter of water developed by self-evaporation must be multiplied by a factor representing the efficiency of the turbine and piping, which is somewhere between 0.65 and 0.75.

Applying these figures to some of the sources of hot water avail-

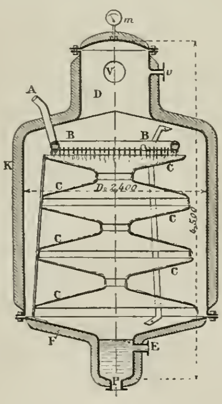

FIG. 5 CAUFOURIER SELF-VAPORIZER FOR GENERATION OF STEAM FROM WATER AT TEMPERATURES OF 50 TO 75 DEG. CENT.

able in France and Africa, the author finds that they are capable of giving outputs of from 100 hp. to as high as 12,200 hp., which, if true, would mean that natural sources of hot water represent a source of power generation which deserves serious attention under certain conditions.

So much for the theory. As far as practical realization of the problem is concerned, the first thing needed is the construction of a self-vaporizer such that heat losses shall be reduced to a minimum, and also of a turbine working at pressures below atmospheric. For this purpose, however, the present exhaust turbine may be conveniently used. As regards the boiler or self-vaporizer, a good deal has been done in the way of producing such apparatus on a small scale in various medical establishments stationed at the natural sources of hot water with a view to increasing the volume of steam for purposes of inhalation. Such is, for example, the "vaporigene" of Doctor Lajaunie, as used at Ax-les-Thermes, built somewhat like an alcohol still. In this the mixture of gas and vapor generated in the upper part is taken up by a suction pump and sent through tubes surrounded by hot water coming

For large outputs the author suggests a generator built roughly as shown in Fig. 5. The outer casing may be made either of steel or of copper according to the character of the salts and gases present in the water. In fact, as the pressure is low and the temperature not in excess of 212 deg. fahr., in some cases the casing might be made of concrete provided the water is of such a character that it does not affect the latter materially. This casing is vertical, cylindrical, and surmounted by a dome D, wherein are located the steam outlet V and the vacuum-pump outlet v. The entire structure should be protected by a good heat insulator K. The water admitted through A flows over a perforated sheet B on to a series of dished annular plates C, alternately inclined first toward the center and then toward the periphery, and provided with flanges partly to make the structure more rigid and partly to guide the flow of water. The entire assembly of plates C is rigidly attached to the bottom F, which is made demountable for purposes of periodic cleaning of the surfaces and its bottom. The solid deposits are cleaned by removing the plates C, while the mud is accumulated in the lower part of the apparatus and may be blown

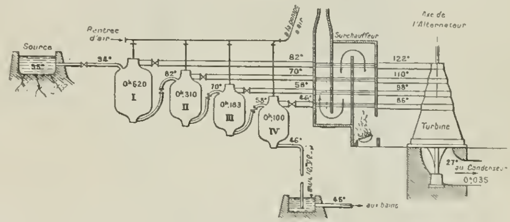

FIG. 6 PROPOSED SCHEME OF INSTALLATION FOR POWER GENERATION FROM NATURAL SOURCES OF HOT WATER

out at P. The cold water is removed through E and may either let out entirely or passed on to the next boiler having a lower pressure of evaporation.

To start the boiler the desired vacuum is created by means of a pump attached to the vacuum outlet v and then hot water is admitted, slowly at first to heat the boiler, and then at the normal rate. Steam if formed on the sheets of water flowing over the plates C and is given off either at the center or along the periphery. In order to make the flow of steam easier the plates C are smaller at the top and larger at the bottom of the generator.

From the generator (Fig. 6) the steam flows to a superheater (surchauffeur) the purpose of which is to dry the steam and raise its temperature from 35 to 40 deg. cent. (95 to 104 deg. fahr.). From the superheater the steam may go either to a series of turbines, or preferably to one low-pressure turbine. The condensers and pumps used would be of the standard types.

It does not appear from data presented in the article that any such machine has ever been built, but the subject is of considerable interest. (*Le Génie Civil*, vol. 78, no. 2, Jan. 8, 1921, pp. 37–39, 2 figs., *d*)

SHIPBUILDING

NEW DESIGN OF 10,000-TON TANKER. Description of a tanker built by Sir W. G. Armstrong, Whitworth & Co., at Newcastle-on-Tyne, England.

The most interesting feature of this vessel is the structural framing which is carried out on the Foster-King transverse system, in which the total weight does not exceed that of the longitudinally framed vessel such as is embodied in the Isherwood system.

In the King system a number of deep longitudinal girders are fitted to the bottom and sides of the vessel and also to the center bulkhead. At the transverse bulkheads these girders are carried athwartships, while one or more deep floors are arranged in each oil compartment according to its length. The deep girders on the transverse and fore and aft bulkheads are so arranged that alternate tanks are left clear for calking. (*Marine Engineering*, vol. 26, no. 1, Jan. 1921, pp. 12–15 and 2 plates, *d*)

STEAM ENGINEERING

Vertical Boiler with Water Purifier

Water Purifier in Vertical Boiler. In locomotive cranes the item of washing and maintenance work on the boiler is of great importance, especially on contract work where such water has to be used as is available.

A locomotive-crane boiler has been placed on the market equipped with an annular scale chamber located between the tubes and the shell plate as shown in Fig. 7.

The feedwater is passed through this scale chamber at about 1/200 of the speed through the intake pipe and attains a temperature at which the scale-forming impurities are liberated from solution without the use of any chemicals. The impurities are then carried in suspension, and as the movement of the water is

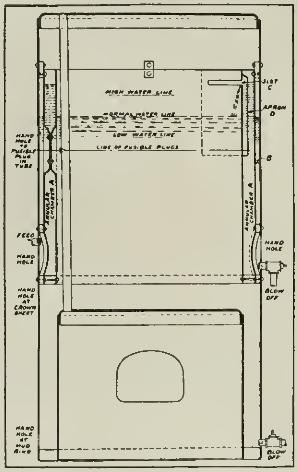

Fig. 7 Parker Locomotive-Crane Vertical Boiler with Water Purifier

very slow these suspended precipitates settle down readily to the bottom of the chamber. This settling is accelerated by the decrease in density of the water as it is heated and by the decrease in its fluid friction.

The purifier consists of the annular scale chamber *A* extending completely around the tubes with a 1-in. water space *B* between this chamber and the boiler shell. The outlet into the main portion of the boiler is the slot *C* guarded by the apron *D*. The feedwater is admitted directly to the scale chamber *A* at a point farthest from the outlet slot. It travels slowly around this chamber to the outlet and reaches, approximately, the boiler temperature before overflowing. The apron shown at *D* keeps any floating impurities, such as grease, oil, etc., from being discharged into the main boiler.

As regards the efficiency of this purifying device, it is stated that in one test of a 42-in. diameter boiler of this type at Paterson, N. J., a feedwater naturally carrying 5 grains per gal. was loaded with 70 grains of calcium and 70 grains of earth, a total of 145 grains per gal. The feed was taken from a barrel agitated with carbonic acid gas to form calcium carbonate. After about 1200 gal. of this kind of water has been passed through the boiler it was allowed to cool, when the heating surface and lower mud ring were found to be perfectly clean and the mud about 6 in. deep in the scale chamber. The blow-offs were both plugged so that all impurities remained in the boiler.

No data as to the relative sizes of the parts or as to cost of construction of the boiler are given by the author in the original article. It is stated that this boiler was designed in 1919 by Thomas T. Parker, formerly chief boiler inspector of the Fidelity and Casuality Company. (*The Iron Trade Review*, vol. 68, no. 4, Jan. 27, 1921, p. 293, 1 fig., *d*)

TESTING (See Abstract on page 193)

WELDING

Properties of Metal in Arc-Fusion Welds

Properties of Arc-Fused Metal, Henry S. Rawdon, Edward C. Groesbeck and Louis Jordan. An extensive paper, of which only the summary can be presented here. A fusion weld is fundamentally different from all other types in that the metal of the weld is essentially a casting. The arc-fusion weld has characteristics quite different from other fusion welds. A preliminary study of a considerable number of specimens welded under different conditions confirmed this general opinion concerning arc welds. A knowledge of the properties of the arc-fused metal is fundamental in any study of electric-arc welding.

Blocks of arc-fused metal of size large enough to permit a tension specimen (0.505 in. diameter, 2 in. gage length) to be taken from each were made under different conditions of fusion. Two types of electrodes, a "pure" iron and a mild steel, were used in the bare condition and also after receiving a slight coating. With these were included a set of similar specimens prepared outside of the Bureau of Standards by expert welding operators.

During the fusion the composition of the metal of both types of electrodes is changed considerably by the burning-out of the carbon and other elements, and the two become very much alike in composition. A very considerable increase in the nitrogen content occurs at the same time.

The mechanical properties of the arc-fused metal as measured by the tension test are essentially those of an inferior casting. The most striking feature is the low ductility of the metal.

All of the specimens showed evidence of unsoundness in their structure, tiny inclosed cavities, oxide inclusions, lack of intimate union, etc. These features of unsoundness are, seemingly, a necessary consequence of the method of fusion as now practiced. They determine almost entirely the mechanical properties of the arc-fused metal. The observed elongation of the specimen under tension is due to the combined action of the numerous unsound spots rather than to the ductility of the metal. That the metal is inherently ductile, however, is shown by the changes in the microstructure produced by cold bending. By taking extreme precautions during the fusion, a great deal of the unsoundness may be avoided and the mechanical properties of the metal may be considerably improved. However, the specimens as described are more representative of actual present practice in welding.

A very characteristic feature of the microstructure of the arc-fused metal is the presence of numerous plates within the ferrite crystals, arranged usually along crystallographic planes. These persist in the metal after prolonged heating; for example, 10 hr. at 1000 deg. cent. in vacuo does not remove them. The various lines of evidence available indicate that they are related to the nitrogen content of the metal, which is increased during the fusion.

Upon heating the metal above the temperature of the Ac_3 transformation, the nitride enters into solid solution in the ferrite and is retained so by quenching. Upon heating this quenched metal the plates reappear and begin to show at a temperature of approximately 700 deg. cent. The effect of nitrogen upon the Ar_3 transformation is very similar to that of an equal amount of carbon. However, there is no evidence of a transformation corresponding to the A_1 or the pearlite change due to the nitrogen in the steel.

Microscopic examination indicates that there is but little, if any, relation between these nitride plates and the path or rupture produced by tension. The effect of grosser imperfections of the metal is so much greater than any possible effect of the nitride plates in determining the mechanical properties that the conclusion appears to be warranted that this feature of the structure is a matter of relatively minor importance in ordinary arc welds.

Judged from the results obtained, neither type of electrode appears to have a marked advantage over the other. The use of a slight protective coating on the electrodes does not appear to affect materially in any way the mechanical properties of the arc-fused metal.

An extensive bibliography of physical characteristics of the metal of the weld and on nitrogen in iron and steel is appended. (*U. S. Bureau of Standards Bulletin No. 179*, 1920, 63 pp., 28 figs., *gA*)

THE MAXIMUM THEORETICALLY POSSIBLE UTILIZATION OF WIND IN WIND MOTORS, Dr. A. Betz. The rising costs of fuel have once more directed the attention of engineers, especially in Germany and the Scandinavian countries, to the use of wind as a source of power generation, and when engineers and not millwrights have tried to design wind-motor wheels, it has been discovered that there is an almost complete lack of knowledge as to the basic elements of the theory underlying the operation of this type of motor. The present article deals with the subject of efficiency of wind motors.

The question of efficiency in the case of wind motors is more complicated than with other prime movers, because it is difficult to determine what should be considered as the amount of power supplied to the motor by the wind. The author of the present article thinks that the power supplied to the motor by the wind should be so determined as to make it proportional to the size of the motor, in particular to the area of the wind wheel.

For example, the windmill can be considered as an inversion of an air propeller, which can be done by imagining that the wheel is moving forward in still air in an axial direction with the velocity of wind v, which substantially is equivalent to having the air move with that velocity against the wheel. If the operation of the windmill be conceived in this manner, it becomes obvious that the energy supplied to the wheel is the energy necessary in order to produce the axial translation of the wheel. If the wind exerts on the wheel a pressure in the axial direction P, then the input of energy per second is equal to P_v, and if the useful work delivered by the wheel at the shaft is L, the efficiency is

$$\eta = \frac{L}{P \times v} \quad [1]$$

This definition of efficiency satisfies the theoretical requirements as it makes it possible to see clearly what the energy supplied to the wheel is and what it amounts to. For practical purposes, however, Equation [1] is unsuitable, as the axial pressure P is a magnitude of only secondary importance for commercial purposes as bearing on the properties of a wind motor. Furthermore the work Pv is not produced at any cost to the owner of the mill.

Of greater importance in practice is the question of how much energy can be produced by a wheel of a given diameter with a given wind velocity. In order to compute the performance of a windmill in this respect, its useful output can be compared only with the kinetic energy which flows per second through a plane equal in magnitude to that of the windmill and assumed to be placed normally to the direction of the wind. If the diameter of the wheel be D, this area is $F = \pi D^2/4$; and if the wind velocity be v, then the energy flowing through that plane per second is

$$E = \frac{\rho}{2} F v^3 \quad [2]$$

where ρ denotes density of the air.

The ratio of the useful output of the windmill at the shaft to the output expressed by Equation [2], or

$$\eta_f = \frac{2L}{Fv^3} \quad [3]$$

may be called the area efficiency.

From this the author proceeds to the determination of the conditions under which for a given wheel area F the largest amount of the energy E in the wind may be converted into useful output, and what is, under these conditions, the area efficiency of the wheel. To do this the problem is conceived in an ideal manner, namely, the windmill wheel is replaced by a surface which opposes a certain resistance to the wind and thereby reduces its velocity and kinetic energy, transforming this kinetic energy into useful work with no losses. Actual windmill wheels differ from this idealized conception mainly by the fact that in their case losses occur in the process of conversion of energy which still further reduce the area efficiency. By employing the idealized conception of the wheel the numerical values of efficiencies are made larger than they can be actually, and represent really the upper limits of efficiency which are never exceeded in actual practice.

why the entire kinetic energy flowing per second through a plane of area F is not converted into useful work by the wheel which also has an area F. The reason is that because of the falling off of the kinetic energy of the air in the windmill wheel, the velocity at which the air flows through the wheel falls off also. The more the energy contained in, say, 1 cu. meter of air is utilized in the windmill, the less the velocity of the air and the less the air that flows through the wheel. There is therefore a certain optimum value of the decrease of velocity of the air at which the product of the volume of air flowing through the wheel per second by the amount of energy abstracted by the wheel per unit of air, is a maximum.

In order to carry out the computations numerically it is necessary to consider with what velocity w the air flows through the surface of the wheel. The velocity of the wind ahead of the wheel is v. Because of the loss of energy at the wheel, its velocity at the rear is v_1. If we denote the mass of air flowing through a section of the wheel surface ΔF as m, then this mass exerts on the wheel a force in the axial direction equal to

$$\Delta P = m(v - v_1) \quad [4]$$

If now the velocity at which the air flows through the wheel is w, the wind does per second the work

$$\Delta L = \Delta P \times w = m(v - v_1)w \quad [5]$$

This work results in a decrease of the kinetic energy in the wind from $^1/_2\, mv^2$ to $^1/_2\, mv_1^2$. If now the work done by the wind is equated with the kinetic energy it contains, then

$$m(v - v_1)w = {}^1/_2 m(v^2 - v_1^2) \quad [6]$$

whence

$$w = {}^1/_2(v + v_1) \quad [7]$$

The velocity with which the air flows through the wheel is therefore the arithmetic mean between the velocities ahead and behind the wheel. Knowing this velocity, we can also easily determine the amount of air which flows through the section ΔF of the wheel per second. Its mass is

$$m = \rho \times \Delta F \times w = \rho \times \Delta F \times \frac{v + v_1}{2} \quad [8]$$

where ρ is the density of the air. If we now substitute this value for m in either Equation [5] or [6], we obtain the value of the work done within the area ΔF, namely,

$$\Delta L = \rho \times \Delta F \times \frac{v^2 - v_1^2}{2} \times \frac{v + v_1}{2} \quad [9]$$

It becomes important at this point to know what must be the value of v_1 or the velocity of the air leaving the wheel, in order that with a given wind velocity v the maximum of work be done at the wheel. The author shows that this happens when v_1 is equal to $v/3$; and furthermore that the wheel of a windmill produces the maximum of its work when

$$L_{max} = \frac{8}{27} \rho F v^3 \quad [14]$$

This is, of course, only the theoretical maximum of output. If the value for L be now inserted in Equation [3], we obtain

$$\eta F_{max} = \frac{2L_{max}}{\rho F v^3} = \frac{16}{27} \quad [15]$$

as an upper theoretical limit of efficiency of the wheel. The actual efficiency however, will be lower, because of the presence of losses in the wheel. (*Zeitschrift für das gesamte Turbinenwesen*, vol. 17, no. 26, Sept. 20, 1920, pp. 307–309, *t*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquires for further information in connection with articles reported in the Survey.

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A.S.M.E.

Research Résumé of the Month

A—Research Results

The purpose of this section of Engineering Research is to give he origin of research information which has been completed, to ive a résumé of research results with formulas or curves, where uch may be readily given, and to report results of non-extensive esearches which in the opinion of the investigators do not warrant paper.

utomotive Vehicles and Equipment A1–21. STARTING AND LIGHTING BATTERIES. The Bureau of Standards has made a brief study of starting and lighting batteries at the request of the Motor Transport Corps of the Army. The curves show the instantaneous demands upon batteries when cranking engines. The initial values of current and voltage have been obtained by the use of the oscillograph and the way in which the rapid decrease of current occurs as well as the pulsations resulting from the compression in the different cylinders is clearly shown. An interpretation of the curves shows that much additional information could be obtained with respect to the operation of the starter system and of the engine itself. The results are qualitative rather than quantitative, but indicate a possibility of using this method for the study of lubrication, ignition, compression and distributor action. In addition, an exact method is secured for measuring the speed from one revolution to another. Measurements were made at different speeds, different throttle openings and different temperatures. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

utomotive Vehicles and Equipment A2–21. CARBONIZATION OF LUBRICATING OILS. Circular 99 of the Bureau of Standards on Carbonization of Lubricating Oils may be obtained from the Superintendent of Documents, Government Printing Office, at 10 cents per copy. The paper contains 44 pages, discusses the nature and effect of the deposits formed in internal-combustion engines, and shows that the term "carbon" is a misnomer because the deposit consists mainly of asphaltic matter. Brief accounts are given of the nature of petroleum oils and theories concerning the formation of deposits. The oxidation and cracking of petroleum are discussed in detail. Carbonization tests which depend upon oxidation and upon cracking are discussed with full description of the apparatus, and procedures for the "Waters" and "Conradson carbon residue" tests are given. The distillation methods are touched upon and the general discussion gives brief summaries of certain controversial papers, and finally it is pointed out that much is to be learned on the subject of lubrication of internal-combustion engines. This paper was prepared by C. E. Waters, Chemist, Bureau of Standards. Address Director S. W. Stratton, Bureau of Standards, Washington, D. C.

'ement and Other Building Materials A4–21. DEFINITIONS AND SPECIFICATIONS OF LIME. Circular 106 of the Bureau of Standards contains a discussion of lime, its manufacture and use. It can be obtained at 5 cents per copy from the Superintendent of Documents, Government Printing Office, Washington, D. C.

'uels, Gas, Tar and Coke A1–21. GAS BURNERS. The Bureau of Standards has been investigating burner design and operation for the Industrial Fuel Committee of the American Gas Association. The result of the first part of the work is covered in a paper entitled The Design of Atmospheric Gas Burners, which will be published shortly. The work refers to industrial burners, but a study has been made of domestic burners for natural gas. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Fuels, Gas, Tar and Coke A2–21. STANDARDS FOR GAS SERVICE. Circular 32 of the Bureau of Standards deals with standards for gas service. A fourth edition of this will be released shortly and will include all changes in the standards for gas service to the end of 1920, including a short discussion of the causes which have compelled changes in the standards and the significance of such changes. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Fuels, Gas, Tar and Coke A3–21. STRUCTURE IN BITUMINOUS COAL. Report Serial 2196 on the Structure of Bituminous Coals, by Rheinhardt Thiessen, Research Chemist of the Bureau of Mines, gives a résumé of the work reported in Bulletin 117 on the Structure of Paleozoic Bituminous Coals recently issued by the Bureau of Mines. The Bulletin contains 296 pages with 160 illustrations and may be obtained from the Superintendent of Documents, Government Printing Office, Washington, D. C., for 80 cents. The report indicates the method of microscopic examination which shows that the coal is made up of parts which were at one time pieces of wood and other parts which contain humic matter, resin, carbonized material and some mineral matter. U. S. Bureau of Mines, Washington, D. C. Address F. B. Foster, Director.

Fuels, Gas, Tar and Coke A4–21. CARBONIZATION OF LUBRICATING OILS. See *Automotive Vehicles and Equipment A2–21.*

Leather and Glue A1–21. LEATHER FROM RABBIT SKINS. Leather made from Australian rabbit skins has been tested at the Bureau of Standards. The tensile strength is low, varying from 800 to 1200 lb. per sq. in., as compared with 4000 lb. for calfskin leather. The leather exhibited little resistance to tearing. Some raw pelts were tanned in the laboratory by the one-bath chrome process, the resultant leather being the same as the original samples. Samples have many surface defects. Could be used for linings, novelties or other similar work. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Leather and Glue A1–21. GLUE DATA. Table 1 gives data regarding certain glues. Forests Products Laboratory, Madison, Wis. Address Director.

TABLE 1 COMPARISON OF FIVE DIFFERENT TYPES OF GLUE

(Prepared by Forest Products Laboratory)

Particular Compared	Animal Glue	Casein Glue	Vegetable Glue	Blood Glue	Liquid Glue
Source	Hides, bones, horns, etc.	Casein from milk	Cassava starch	Dried blood	Animal glue or fish parts
Cost per lb. 1920	25–42 cents	16–20 cents	10–12 cents	20 cents	\$1–\$5 per gal.
Spread in sq. ft. per lb.	25–35	35–55	35–50	30–100	No data
How mixed	Soaked in water and melted	Mixed cold with rapid stirring	Mixed with alkali and cold or hot water	Mixed cold	No preparation
How applied	Warm with brush or mechanical spreader	Cold with brush or mechanical spreader	Cold with mechanical spreader, not by hand	Cold with brush or mechanical spreader	Cold or warm usually applied by hand
Temperature of press	Cold, or with hot cauls	Cold	Cold	Hot	Cold
Strength (in shear (test)	High grades stronger than strongest woods	Equal to medium-grade animal glue	Equal to medium-grade animal glue	High strength in plywood. Not used for joint work	Best grades equal to medium-grade animal glue
Water resistance	Low	High	Low	High	Low
Chief uses in woodworking	For strong joint work	For water-resistant plywood or joint work	For veneer work because of cheapness	For water-resistant veneers	For repair work and small articles

Metallurgy and Metallography A7–21. HARDNESS OF STEELS BY ABRASION. The relative hardness of various types of steels produced by subjecting all of them to the same abrading influence has been determined with the following results: In all cases except the high-carbon austenitic steel no pronounced effects of the abrasion were observed. The hardness of carbon steel is increased and that containing 0.85 per cent carbon shows the greatest increase. Alloy steels generally show a smaller increase in hardness of the abraded surface and in some cases show a decrease of hardness. High-carbon austenitic steels show a marked decrease of Brinell and scleroscope hardness. This process of abrasion viewed in the light of Beilby's theory may be considered as resulting in the production of amorphous matter at the expense of crystalline matter which affects the hardness of the abraded surface of the metal but probably not the general character of its structure. The decrease of hardness in the high-carbon austenitic steel may be caused by the martensite being present in a greater amount in the lower layer of the examined specimen than in the inner portion according to Benedick's pressure theory, and it seems possible that if the surface layer is ground away the next or more austenitic layer should be found somewhat softer. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Metallurgy and Metallography A8–21. TEMPER BRITTLENESS OF STEELS. An extensive view of the literature on this subject has been made with the result that the nature and occurrence of temper brittleness may be summarized as follows: Certain steels which have been hardened by quenching from temperatures above the A_3 point and tempered at temperatures ranging from about 450 to 600 deg. cent. show less impact values if they are cooled slowly from tempering temperature as compared with those cooled quickly. The cause of this phenomenon, which is also referred to as "Krupp Krankheit" has not been clearly established. The property of temper brittleness has been found present in carbon steel (0.25 to 0.4 per cent), nickel, chrome-nickel, chromium and certain other alloy steels. Chrome-nickel steels of the same chemical composition and heat treatment have been found to

than the quickly cooled ones. The process of manufacture appears to have more of an influence than small changes in chemical composition; thus, steels made by the acid open-hearth process are more prone to temper brittleness than electric or crucible steels. The opinion has been advanced that the degree of work and the temperature employed during the process of fabrication from the ingot bear some relation to the degree of susceptibility to temper brittleness. Other factors appearing to have an influence on the subject are the temperature of hardening preceding tempering treatment; degree of hardening, as cooling in water, oil or air; the rate of cooling from tempering temperature; phosphorus content; and the furnace atmosphere in which the material is treated. Other questions bearing upon the problem and upon some of which no general agreement has been reached and concerning which but little knowledge appears to be available are: relations between microstructure and susceptibility to temperature brittleness; path of rupture; heating and cooling curves; relation between impact values and tensile-test values as well as the Brinell hardness values; and the influence of the shape of the notched specimen upon impact-test values. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Mining, General A2–21. Coal-Mine Fatalities in 1920. During 1920 there was a marked decrease in the number of fatal accidents. In the first eleven months of the year 1983 men lost their lives. This was 163 less than the corresponding period of the previous year. This decrease amounts to 7.6 per cent and during this period the output was 16 per cent greater than in 1919. The production from January to November was 585,000,000 tons. The number of lives lost per million was 3.39 in 1920 as compared with 4.28 in 1919. This is covered in Report 2197 by W. W. Adams. Bureau of Mines, Washington, D. C. Address F. Bain Foster, Director.

Mining, General A3–21. Miners' Flame Safety Lamps in Gaseous Coal-Dust-Laden Atmospheres. Report 2199 by L. C. Ilsley and A. B. Hooker gives the results of tests carries out in a special gallery constructed by the Bureau of Mines. Coal dust which passed through a 200-mesh screen was fed into a compressed-air line. The air line was also charged with natural gas. The tests were made by subjecting the lamps to conditions known to be on the border of failure without coal dust and then coal dust was added. No tests were made with velocities exceeding 2500 ft. per min.

As soon as the coal dust was added a change could be noted. Thirteen failures occurred out of fifty tests with unbonneted lamps and two of the thirteen failures were caused by the addition of coal dust. No failure occurred from 38 tests with bonneted lamps. The conclusions of the tests are that unbonneted lamps are less safe in atmospheres containing coal dust, provided the lamp is suddenly brought into such atmosphere when its gauze is at a bright-red temperature. Bonneted lamps are affected less by the addition of coal dust. In extremely dusty atmospheres there might be a greater tendency for the glasses to crack. Bureau of Mines, Washington, D. C. Address S. B. Foster, Director.

Paints, Varnishes and Resins A1–21. The following specifications have been prepared by the Bureau of Standards:

Circular 102:—Recommended Specification for Composite Thinner for Thinning Semi-Paste Paints when the Use of Straight Linseed Oil is Not Justified.

Circular 103:—Recommended Specification for Spar Varnish.

Circular 104:—Recommended Specifications for Asphalt Varnish.

Circular 105:—Recommended Specifications for Liquid Paint Drier.

These may be obtained from the Superintendent of Documents, Washington, D. C.

Refrigeration A1–21. Non-Condensible Gases. Technologic Paper 180 on the Cause and Prevention of Formation of Non-Condensible Gases in Ammonia Absorption Refrigerating Machines, by E. C. McKelvey and Aaron Isaacs, was issued in October, 1920. It may be obtained from the Superintendent of Documents, Government Printing Office, Washington, D. C., at 5 cents a copy. The paper covers ten pages and discusses the effects of non-condensible gases in ammonia machines and then describes experiments with distilled water and aqua ammonia. It also discusses the method of determining carbon dioxide in small amounts and the methods for preventing gas formation. A summary of the paper follows:

1 The non-condensible gases found in ammonia absorption refrigeration machines are due to either or both of two causes, namely, (*a*) leaks of air into the system and (*b*) the corrosive action of the ammonia liquor on the metal of the plant.

2 When the foul gas is mainly nitrogen, the gas is derived from air that has leaked into the system, and leaks should therefore be sought. The oxygen in the air is very quickly used up and so will be present in only a very small percentage of its original amount. If the foul gas is hydrogen, the cause is corrosion of the ammoniacal liquor. A gas containing both nitrogen and hydrogen shows both causes to be present.

3 If a solution of sodium or potassium dichromate is added to the generator charge so that the charge in the generator will contain the salt to the extent of 0.2 per cent by weight, all foul-gas formation from the corrosive action of the ammonia charge will be stopped. It is recommended that the dichromate be added in all cases, as it has been found that its presence decreases the very small amount of gas caused by even the highest-grade ammonias.

4 A method is given for the quantitative estimation of carbon dioxide in ammonia.

Ventilation A1–21. Automatic Control of Humidity in Shops. Technical Notes 121, Forest Products Laboratory, discusses the automatic control of humidity in shops. The apparatus developed at the Forest Products Laboratory has kept the woodworking rooms of the laboratory at a uniform temperature and humidity during the whole year. The instrument requires little personal attention. The principle upon which it acts is that of bringing the air to the dewpoint temperature for the desired atmospheric condition, saturating it with moisture at that point and then heating it without the addition of moisture to the required room temperaure. Thus if too wet or too dry originally it is brought to the proper condition. The apparatus consists of a small cabinet or chamber through which the air is drawn as often as it needs to be conditioned. The conditioning chamber contains water sprays, the temperature of which is kept constant by a mixing valve. The air then leaves the chambers and is heated to room temperature by coils. Drawings and further details may be obtained on application. Forest Products Laboratory, Madison, Wis. Address Director.

Wood Products A1–21. Dry-Kiln Construction. Any building materials may be used. The choice depends on relative importance of first cost, maintenance and fire hazard. A well-built wood kiln is very satisfactory. The chief objection aside from fire risk is the tendency to swell and shrink, causing working of the frame and loosening of the nails. All lumber should be thoroughly seasoned. Fir, Douglas fir, yellow pine, redwood, cypress and similar woods with low shrinkage rates should be used for sheathing and sills. Good straight-grain material for frames. Sheathing should be in ship-lap form, laid horizontally and nailed twice to each stud at the middle and bottom of the board. Outside walls should be sheathed on both sides or sheathed inside and plastered outside. They should be insulated with a good moisture-proof, heat-resistant insulator. Quilt insulation between waterproof paper has not proven satisfactory. Walls should be painted with asphaltic paint. Where lumber is plentiful, crib or laminated structure may be used, employing 2-in. by 6-in. planks laid flat. Roof of similar material on edge.

Brick of hollow style is more satisfactory than wood where permanency is desired. Walls should be laid in tempered cement mortar. Unequal expansion caused by the difference in temperature of the outer and inner faces may cause cracks, which should be painted with elastic cement rather than mortar. The tile should be chosen so that openings run horizontally rather than vertically. Walls of monolithic concrete or concrete block are highly absorbent of moisture. Forest Products Laboratory, Madison, Wis. Address Director.

B—Research in Progress

The purpose of this section of Engineering Research is to bring together those who are working on the same problem for coöperation or conference, to prevent unnecessary duplication of work and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

Machine Tools B1–21. See *Metallurgy and Metallography B5–21.*

Metallurgy and Metallography B5–21. Magnetic Testing of Twist Drills. The Bureau of Standards is taking part in a coöperative investigation by a Committee of the A.S.T.M. on testing drills by magnetic analysis. Steel has been especially prepared for the investigation and it has been tested for homogeneity by a magnetic method at the Bureau. Drills are to be manufactured under carefully controlled conditions, after which they will be again tested magnetically. The drills are then to be tested mechanically and an attempt made to correlate mechanical performance of the drills with the magnetic tests. The object of the investigation is to develop an apparatus to test drills in a commercial way without destroying them. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

C—Research Problems

The purpose of this section of Engineering Research is to bring together persons who desire coöperation in research work or to bring together those who have problems and no equipment with those who are equipped to carry on research. It is hoped that those desiring coöperation or aid will state problems for publication in this section.

Machine Design C1–21. Shafts in Bronze Bearings. The behavior of steel shafts with various carbon contents when running in bronze bearings is desired. This should refer to friction, wear and similar data. Address S. A. Hand, Associate Editor, *American Machinist*, New York City.

D—Research Equipment

The purpose of this section of Engineering Research is to give in concise form notes regarding the equipment of laboratories for mutual information and for the purpose of informing the profession of the equipment in various laboratories so that persons desiring special investigations may know where such work may be done.

Scovill Manufacturing Company D1–21. Equipment. Apparatus for electrical measurements of the following range:
Resistance from 1×10^{-6} ohm to 1×10^{7} ohms.
Inductance from 1×10^{-5} henry.
Capacity from 1×10^{-4} microfarad.
Voltage from 1 millivolt of any frequency.
Current from 0.1 milliampere of any frequency.
Breakdown voltages up to 30,000 volts.

The laboratory is equipped with platinum thermocouples, standard pure metals for melting-point measurements, General Electric oscillograph, complete radio apparatus for generation, study and use of high frequencies; accoustic apparatus, including visual electric noise indicator developed in the laboratory for quantitative, relative indication of loudness of sound, a dictograph loud speaker, a callophone loud speaker, a Winkler-Reichman loud speaker, a magnavox telemegaphone, microphones, receivers, transformers and generators.

Galvanometers, voltmeters, ammeters, wattmeters, inductances, capacities, Wheatstone bridges, capacity bridges, inductance bridges and potentiometers are also found in the laboratory.

The laboratory is equipped with selenium cells, constant-frequency and speed apparatus, an Evershed bridge megger and three electric furnaces.

The laboratory force consists of four technical men, four meter men, one jeweler, one high-grade mechanic, one helper and two apprentices.

The laboratory is located in a two-story brick building, the first floor containing a fully equipped machine shop, special research rooms, several motor-generators and storage space. The second floor contains the meter department, the standardizing, high-current and high-frequency tables and space for miscellaneous testing and special set-ups with the time-signal apparatus and desk space. The laboratory is provided with 110–220 volt d.c. and a.c. current and 440–volt, three-phase, 60 cycle a.c. current. In addition there is 110-volt emergency storage-battery lighting system and a storage battery for currents up to 500 amperes at three volts. Laboratory apparatus will give constant frequency between 60 and 80 cycles at 110 volts and high freqneneies of 1000 cycles and above for small currents. Two-phase current may be obtained at any frequency up to 133 cycles.

The laboratory is used for development of inventions and the perfection of manufacturing methods with the development of theory underlying the action of new electrical apparatus. It makes tests for the Sales Department, for the Purchasing Department and for the Manufacturing Department. It performs technical service regarding time-signal reception for the regulation of the electric-clock system and the maintenance of X-ray apparatus. The service is extended in the Meter Department to the installation, maintenance and repair of electrical switchboard instruments and service meters, pyrometers and thermometers, and the monthly checking of switchboard meters with portable meters which are calibrated periodically against laboratory standards. Address Scovill Manufacturing Company, Waterbury, Conn. Attention R. S. Sperry.

E—Research Personnel

The purpose of this section of Engineering Research is to give notes of a personal nature regarding the personnel of various laboratories, methods of procedure for commercial work or notes regarding the conduct of various laboratories.

F—Bibliographies

The purpose of this section of Engineering Research is to inform the profession of bibliographies which have been prepared. In general this work is done at the expense of the Society. Extensive bibliographies require the approval of the Research Committee. All bibliographies are loaned for a period of one month only. Additional copies are available, however, for periods of two weeks to members of the A.S.M.E. or to others recommended by members of the A.S.M.E. These bibliographies are on file in the offices of the Society.

Metal Manufacturing, Miscellaneous F1–21. Forging and Finishing Claw Hammer Heads. A bibliography of 1/2 page. Search 3243. Address A.S.M.E., 29 West 39th St., New York.

Petroleum, Asphalt and Wood Products F2–21. Bibliography of Petroleum and Allied Substances 1917. The Bureau of Mines has issued Bulletin 120 giving the Bibliography of Petroleum and Allied Substances for the Year 1917. This may be obtained from the Government Printing Office, Superintendent of Documents, Price 25 cents.

Properties of Engineering Materials F2–21. Fluorspar. A bibliography of three pages. Search 3240. Address A.S.M.E., 29 West 39th St., New York.

CORRESPONDENCE

Contributions to the Correspondence Department of Mechanical Engineering are solicited. Contributions particularly welcomed are discussions of papers published in this Journal, brief articles of current interest to mechanical engineers, or suggestions from members of The American Society of Mechanical Engineers as to a better conduct of A.S.M.E. affairs.

DeLamater Ericsson Tablet Fund

To the Editor:

The following subscriptions to the DeLamater Ericsson Tablet Fund have been received from members of the A.S.M.E.:

S. and V. D. Bevin	$10
A. Falkenau	5
A. Hollander	1
D. S. Jacobus	5
D. J. Lewis, Jr.	5
J. W. Lieb	10
G. M. Newcomer	10
A. Schein	3
H. R. Towne	50
	$99

Further subscriptions will be duly reported.

H. F. J. Porter, *Chairman,*
DeLamater Ericsson Tablet Committee.

New York, N. Y.

The St. Lawrence River Project

To the Editor:

Having read in the correspondence columns of Mechanical Engineering and elsewhere much pro and con discussion of this subject, it may be permissible for one who is familiar with the St. Lawrence River to state some facts for the benefit of those who would like to give some consideration to the subject without devoting much time to the question.

Measured as to any one of its qualities, the St. Lawrence is one of the greatest rivers of the world. But, measured as to all its qualities collectively, it is the greatest. From the standpoint of history and discovery it occupies a prominent position. The Gulf of St. Lawrence was probably entered by Norsemen as early as 1000 A.D., the accounts of Lief Ericsson and his followers clearly indicating that they were in the gulf at that date, though the discovery of the river is credited to Jacques Cartier in 1534. Since the time of Champlain, about 1600, it has been a traveled pathway to the heart of North America. To the early explorers and later developers of the continent it was by far the most important pathway. The explorers passed up the St. Lawrence through the Great Lakes, or along their shores, to the plains of the West and down the Mississippi River.

The St. Lawrence River is remarkable for its magnitude, for the stability of its bed, and for its beautiful shores and islands, affording innumerable summer homes for those who love nature. It drains some 300,000 square miles of area, of which 100,000 is water surface of the Great Lakes. Lake Superior is 1000 ft. deep, its bottom reaching 400 ft. below sea level. Such great natural reservoirs give the river a unique status as to the uniformity of its flow and as to the absence of destructive floods. The remarkable clarity and purity of its waters result in large measure from the influence of the lakes.

When it comes to national, in fact international, economics, the St. Lawrence River is superlatively paramount. Though

evading many shallow rapid sections; though there are a number of important water powers now developed, yet the possibilities as to navigation and water power have scarcely been touched. The surface of Lake Ontario is about 245 ft. above sea level and the average available flow is about 220,000 cu. ft. per sec. Thus there are now being wasted in hydraulic friction some 6,000,000 hp., by far the greater portion of which can be recovered by a comprehensive scheme for ultimate expansion which must, by all means, provide for the greatest possibilities of navigation by ocean-going vessels. There must be no mistake as to capacity. It should be determined by a congress of the competent representatives of all the interests and nations concerned.

The importance of the St. Lawrence River and its possibilities to the world in general, and to the evolution of American civilization in particular, is so vast and so intrinsically meritorious that any great and truly comprehensive project will be self-promoting to the point of realization. B. F. Groat.

Pittsburgh, Pa.

Contends That Monotony Is Not Objected to By Operators on Repetition Processes

To the Editor:

Mr. Gibbons in the January number speaks of monotony of operation and takes it for granted that operators on repetition processes have difficulty on account of monotony.

So far as I know, there is no evidence whatever to support this view. I have made some personal investigations and find that operators on repetition processes make no complaint whatever regarding monotony. In fact, in many cases, I have seen definite indications that the fact that the operator has to make no mental effort, is considered as a distinct advantage. This seems to indicate that the present system of monotonous repetition work distinctly conserves human life of the average repetition worker.

West Lynn, Mass.

Music Hath Charms But Not Power

To the Editor:

I notice in your valuable journal in an article on "Measuring the Two-Hundred Millionth Part of an Inch," on page 59 of your January issue, near the bottom of the 2nd column, there is a repetition of an old fallacy, which ought to have been dead and buried long ago without any possible resuscitation. It occurs in the words: "Many years ago it was stated that it would be possible to wreck the Brooklyn Bridge by means of a violin so played that the vibrations set up would always be in unison with the oscillations of the bridge. Whether this can be done or not is not very important." The plain truth is that it cannot be done, and whoever first inflicted such a statement on the public did not know what he was talking about. I heard this statement repeated many years ago in what purported to be scientific lectures, which to this extent were simply impositions on the credulity of the audience. Any vibrating structure like a bridge is subject to large internal losses by the imperfect elasticity of the structure, and even the turbulence of the air surrounding a large structure in vibration would consume considerable energy, and yet the tiny amount of energy radiated by a violin string—most of which would not even enter the resonant structure but spread into the surrounding void—is supposed to be enough to wreck such a structure as the Brooklyn Bridge. The thing is so absurd that one wonders why this fallacy should ever be repeated in print or in any other way. It is a fantastic statement from beginning to end. Just think of the loud note that the bridge itself would have to utter in unison with the violin before the bridge fell!

Elihu Thomson.

West Lynn, Mass.

To the Editor:

In looking into the literature on the subject of milling-machine feed systems I have been much impressed by the lack of systematic investigation and even, frequently, of reasonably straight analysis in connection with the data already at hand. A case in point, not so much connected with the action of a milling cutter as with the functioning of a milling machine, is the question of the two types of feed systems. This was brought more distinctly to the fore by the definite stand taken in a recent article in favor of a machine driven from the spindle.[1] The best current practice has rejected this feed system. The new system of constant-speed feed shaft lends itself to very rigorous demonstration as being in all ways superior to the system formerly in vogue.

There are two different systems of feed mechanisms used in milling machines. The older one has the feed mechanism driven from the spindle of the machine. The modern method uses a separately driven feed shaft running at constant speed.

The following six statements are submitted in logical sequence, some being axiomatic:

1 In discussing the action of milling, *feed per tooth* is the fundamental quantity
2 A large-diameter cutter will have more teeth than a small cutter
3 One tooth in a large face mill will take a heavier cut than a tooth in a small end mill
4 Peripheral speed is approximately constant for a given quality of cutter and of material. It follows that the large-diameter mill will be used in conjunction with slow speeds and small-diameter mills in conjunction with high speeds
5 A large-diameter cutter will call for a larger feed per revolution than a small-diameter cutter does. (See statements 2 and 3.)
6 Slow spindle speeds will call for heavy feeds per revolution and fast spindle speeds will call for light feeds per revolution. (See statements 4 and 5.)

For simplicity consider a machine with four speeds: n, rn, r^2n, and r^3n revolutions per minute. Assume similarly four gear changes in feed box in geometrical progression. When spindle speed is n, let smallest table travel be a inches per revolution of spindle. Let the ratio of successive changes of gears in feed train be s. For simplicity s and r may be assumed equal, as is often approximately the case, and Tables 1 and 2 may be obtained, giving the table travel per revolution of spindle for the above conditions under each of the systems.

TABLE 1 MILLING-MACHINE FEEDS: FEED SHAFT DRIVEN FROM SPINDLE

Spindle Speeds	Feed Per Revolution			
n	a	ra	r^2a	r^3a
rn	ra	r^2a	r^3a	r^4a
r^2n	r^2a	r^3a	r^4a	r^5a
r^3n	r^3a	r^4a	r^5a	r^6a

TABLE 2 MILLING-MACHINE FEEDS: CONSTANT-SPEED FEED SHAFT

Spindle Speeds	Feed per Revolution			
n	a	ra	r^2a	r^3a
rn	$\frac{a}{r}$	a	ra	r^2a
r^2n	$\frac{a}{r^2}$	$\frac{a}{r}$	a	ra
r^3n	$\frac{a}{r^3}$	$\frac{a}{r^2}$	$\frac{a}{r}$	a

By an analysis of the two tables the following points may be observed:

a In both systems the feed gear box gives a flexibility with the lowest spindle speed from a to r^3a inches feed per revolution of spindle

b In machine with feed train driven from spindle a feed per revolution of r^3a to r^6a is given with highest spindle speed

c In machine with constant-speed feed shaft, a feed per revolution of a down to a/r^3 is given with highest spindle speed.

In conclusion it may be stated that if a be adjusted in each case to make machines equally good with lowest spindle speed, then the constant-speed feed shaft machine has a region of finer feeds

[1] Supplement to Frederick W. Taylor's "On the Art of Cutting Metals," Carl G. Barth, *Industrial Management*, July 1920, pp. 49–52.

per revolution available with the highest spindle speed, whereas the other machine has coarser feeds per revolution available with the highest spindlespeed. This is just the reverse to requirements. (See statement 6.)

Similarly, if a be adjusted to make the machines equally advantageous with highest spindle speed, the machine with spindle-driven feedshaft would have inefficient slow feeds per revolution at the lower spindle speeds.

The constant-speed feed shaft projects the total flexibility furnished by the gear box into the region where needed. The spindle-drive machine does not, so a large part of the flexibility furnished by the gear box is wasted.

A study of the two tables bears out the following statement: If the same range in useful feed per revolution is insisted upon in both machines, then the spindle-driven machine must be furnished with *seven changes of feed gears instead of four*, namely, a/r^3, a/r^2, a/r, a, ra, r^2a, and r^3a, or r must be increased to p, say, where $p^3 = r^6$, or $p = r^2$, with a corresponding decrease of efficiency, of course.

The writer believes that there is no single tenable argument in favor of the machine with the feed mechanism operated from the spindle. Current practice would indicate that this is being more and more appreciated by leading milling-machine manufacturers.

John Airey.

Ann Arbor, Mich.

Appraisal Principles Applied to Industrial Properties

To the Editor:

A careful perusal of such articles concerning appraisals and valuations as have come to the attention of the writer within the past two years, has led him to the conclusion that opposite principles are in use by different engineers, and, moreover, that nearly all such articles deal only with one class of property to be appraised or valued, namely, public-utilities companies.

Within the period embraced from the signing of the armistice to the present day, business men and executives have had their attention focused on valuation of their property for many reasons, a principal one of which was the settlement of Government contracts, another the excess-profits taxes, and another the rapid rises in replacement costs of plant or equipment necessitating readjustment of insurance. Nearly all of these valuations fall within the industrial class. Some confusion exists in the minds of the average business man concerning the terms used by all in appraisal work. The writer would like to define an appraisal as "a measure of economic worth," and in explanation of this statement explain that the common medium or standard of this measure is money.

For the purpose of this discussion the division of appraisals into two classes is made so that a comparison may be readily instituted and in order to show that the governing principles of the appraisal as applied to the two divisions vary somewhat. The divisions consist of public-utility properties and industrial properties.

To ascertain just what should govern the appraisal, an examination of the use to which the appraisal is to be put should be made. With this end in view, the writer enumerates the principal uses of appraisals, either public-utility or industrial, as follows: They are as a basis for, first, establishing rates for service or product second, charges for depreciation and depletion; third, tax returns, federal, state, and municipal, fourth, amounts of insurance to be carried; fifth, issuance of bonds or capital stock; sixth, mergers or consolidations; seventh, bank credits; eighth, purchase, sale or lease of property; ninth, settlement of estates; tenth, settlement and adjustment of partnerships; eleventh, court decisions.

An analysis of the reason for the first use in connection with a public utility discloses that it is made invariably for the securing of a fair rate of return on the investment to the stockholder or bondholder, while in the case of its use by an industrial concern it is desired, in order to obtain a fair rate of return on the investment and in addition so that the concern may be in a position to secure the maximum rate possible under existing economic conditions. Therefore an appraisal of the property for this purpose in the case of public utility is usually based upon first cost, while in the case of an industrial company two appraisals may be made, the first on a basis of original cost and the second on a cost of reproduction of like plant today, new and under existing conditions. There has recently been handed down a decision by Judge Valkenburgh of the U. S. District Court, Kansas City, Mo., against the Missouri Public Service Commission enjoining them from enforcing a rate based on original cost on the grounds that the commission's original cost basis was in violation of the fourteenth amendment to the Constitution. Whether or not this decision by the Circuit Court will be upheld by the Supreme Court remains to be seen.

An examination of the second use—whether for public utility or industrial property—leads the writer to reason that if the appraisal is to be in conjunction with another it should be made upon the same basis as the appraisal it is to be used with, except in the case of Federal taxes noted below.

In the case of an appraisal for the third use, either public utility or industrial, only the first subdivision, Federal taxes, will be dealt with. We are here confronted by a law modified and restricted by decisions from the Treasury Department, which, roughly, may be summarized as follows: "Cost at date of acquisition shall be used; if cost is not ascertainable a fair value as of March 1, 1913, is to be used."

The first portion of the quotation from the revenue act quite clearly indicates that cost is the controlling element as of the date of building or purchase and that any rise in value was not intended to be considered. For the purpose of establishing depreciation rates in connection with Federal taxes, the fair value as of March 1, 1913, may be used. It may be well to state that under the restrictions of the revenue act as generally interpreted, the use of the word "appraisal" is erroneous. In reality, for the purpose of addition to capital an inventory at cost is the allowable use. But for the purpose of establishing a depreciation rate an appraised fair value as of March 1, 1913, of such inventory is used.

Space limitations will not permit the enumeration of appraisals as effected for use as a basis for the various state and municipal taxes, as there are many different regulations by different states and cities.

In the case of the fourth use, whether utility or industrial, it would seem ridiculous for any business concern to insure for its cost, when today the money derived from insurance would replace one-half or one-quarter of the plant. Therefore, the only basis the writer can see that is fair is one that is based on present reproduction under today's existing conditions, taking into consideration future prices during the period to be covered by the policy.

An analysis of the fifth use quite properly shows that the bondholder would wish to know the present value of the property behind his bond. He is only relatively concerned with the past cost but is most intimately concerned with its future value, and so likewise is the stockholder. Both bondholder and stockholder are concerned also with the company's earning power, and therefore to the writer's mind an appraisal falling under this class should be based on a cost of reproduction of the property under existing conditions and prices, keeping in mind any probable fall or rise in prices affecting its reproduction value in the future and as a further governor of value a very close examination of its future earning power.

Quite obviously the purpose of the sixth use of an appraisal for the merging or consolidation of either public utilities or industrial companies is to give each its relative present worth, measuring both in cost to reproduce today and in earning capacity. It should be easily seen that one company may have cost originally more but can be replaced cheaper today than another on account of changes in local conditions, and therefore the only correct basis of appraisal is on cost of reproduction today.

Bankers are concerned when using an appraisal the same as the seventh with, first, the present cost of the property and earning power, and second, the future value. The first cost to them is largely a gage of the growth of the concern, and while perhaps

the only one proper to use.

An examination of the eighth, ninth and tenth uses shows that they fall quite naturally into the same class as the fourth. The purchaser of a property will naturally be governed in his purchase by the reproduction of a like property under existing conditions today, that is, present cost. Should he fail to be offered the property at or near this cost he could very obviously build himself, whereas the seller is concerned with getting the worth of his property today as may be governed by existing economic conditions. These same reasons may be said to apply to an appraisal for the leasing of a property or the settlement of an estate or a partnership.

The eleventh use of an appraisal, as a basis of court decisions, will be governed as to whether it is based on first cost or present cost by its application. This may be illustrated by an example: If condemnation of property were made in the year 1918, the appraisal in this case would be based on cost as of 1918, for obviously if as of 1910 it would be unfair to the one who would receive the damages, and if as of 1920 unfair to the one who was to pay such damages. James S. Brown.

New York City.

A Plea for Proper Setting of Double-Reduction Marine Gears

To the Editor:

The following data were taken on board the S. S. *Carenco* en route from Glasgow to Baltimore in ballast: Mean draft, 14 ft. 11 in.; draft forward, 11 ft.; aft., 18 ft. 10 in.; length of hull, 401 ft.; beam, 54 ft.; full draft, 24 ft. 6 in.; deadweight tonnage, 7825; equipped with General Electric turbine and double-reduction gears of 2500 shaft hp.; engine speed, 3234 r.p.m.; gear reduction, each being an average of five readings taken in succession. After two diagonally opposite corners had thus been checked, the bridge arm was swung to the remaining corners and a similar check was made. It will be noted that there are three readings taken on November 9; in each case the ship was swung off her course to bring the sea on the port and the starboard bow as indicated, and in each case the deflections are the greatest in the gear case in the direction of the progress of the sea under the hull of the ship. It will also be noted that for the readings taken on November 16 and 17 the wind and sea conditions are exactly reversed and that in each case the deflections are the greater on the windward side of the ship.

It is also readily seen from the two sets of readings taken on November 17 that as the sea increases the deflections in the gear case increase in proportion. Also the readings taken on November 18 plainly show that the long swells which succeed a strong wind cause deflections fully as great as when the ship is operating in a storm. The readings taken on November 20 were after the ship had entered Chesapeake Bay, where no wind or sea was encountered, and serve to show the accuracy of the instrument with which these checks were made.

While this ship was en route from Baltimore to Glasgow in loaded condition, very heavy following seas were encountered, in some cases running as high as 20 ft., at which times deflections of 0.050 in. were recorded. When gears of this type are so mounted that deflections of the kind under consideration occur, the case is so warped that the pinions are thrown at an angle with the driving face of the gear; and at a time when the overload becomes 100 per cent, due to surges of sea on the propeller, and with about 50 per cent of the pinion face bearing on the gear face there is an overload on the driving face of the teeth of 400 per cent, this occurring approximately every eight seconds.

TABLE 1 DEFLECTIONS OF GEAR CASE OF DOUBLE-REDUCTION GEAR ON BOARD S. S. "CARENCO" UNDER VARYING CONDITIONS OF SEA AND WIND

Date	Direction of Sea	Direction of Wind	Condition of Sea	Condition of Wind	Ship Riding	Deflection in Inches: Port Forward	Starboard Forward	Port Aft	Starboard Aft
11-6-20	Stb. bow	Stb. bow	Moderate	Moderate	Rolling and pitching easy	0.014	0.020	0.012	0.022

35.9 to 1. The gear on which this check was made was 12 ft. 4 in. in length by 8 ft. 6 in. wide on the foundations.

Due to the considerable difficulty experienced in the operation of double-reduction marine gears for propulsion, a number of theories have been advanced for the cause of failure in the gear teeth. I will not attempt to enter into a discussion of the merits of the various theories, but simply give the results obtained that we may more fully appreciate the conditions under which these gears have to operate.

In order to obtain the figures given in Table 1, a tram was constructed with a revolving head similar to an engineer's transit, and equipped with a seamless drawn tube extending in opposite directions 7 ft. from the center, this tubing being trussed with piano wire to make it as nearly rigid as possible. This apparatus was secured to a pad bolted to the center of the gear-case cover. When the arms were swung diagonally across the gear case, a pin gage to which was attached a Starrett indicator was used at each corner of the gear, two engineers taking the readings between the corner of the gear-case frame and the under side of the bridge arm simultaneously.

To obtain a marine gear that will be entirely successful, therefore, it must, in my judgment, be mounted in such a manner that the deflections of the hull will not be transmitted to the gear case.

S. K. French.[1]

Hog Island, Pa.

Manganese steel, the invention of Sir Robert Hadfield—to whom the John Fritz Medal for 1921 has been awarded, even after special heat treatment is so hard and tough that it can only be machined by grinding. This is slow and costly, an article in the *American Machinist* of January 13, 1921, stating that it is the average occurrence for an 18-in. abrasive wheel with 2-in. face to wear away at the rate of one inch of diameter per hour of use. Wheels are usually run at a peripheral speed of 5000–6000 ft. per min., a feed of from $^1/_4$ to $^1/_2$ in. per revolution of the work, and a depth of cut of from $^1/_{64}$ to $^1/_{100}$ in. The wheels best suited for such work are from 10 to 24 in grit and from M to T in grade.

[1] Gen. Supt., Propulsion Machinery Dept., American International Shipbuilding Corporation.

WORK OF THE A.S.M.E. BOILER CODE COMMITTEE

THE Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York, N. Y.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval after which it is issued to the inquirer and simultaneously published in Mechanical Engineering.

Below are given the interpretations of the Committee in Cases Nos. 312, 313, 318, and 322 to 330 inclusive, as formulated at the meeting of December 6, 1920, and approved by the Council. In accordance with the Committee's practice, the names of inquirers have been omitted.

Case No. 312 (Reopened)

Inquiry: Is it necessary in the construction of small Star-type water-tube boilers for steam heating which are to carry more than 15 lb. pressure at times, to drill the inside and outside ends of staybolts? It is believed that it was the intent of the Committee to cover in this requirement the waterlegs at front and back ends which are considered as headers.

Reply: If the grate area is more than 15 sq. ft., the staybolts are less than 8 in. in length, and the pressure exceeds 15 lb., it will be necessary to drill the staybolts in order to comply with the Code requirements.

It is the opinion of the Committee that the staybolts in the side sheets and that portion of the tube sheets below the tubes of boilers of this type, need only be drilled on the outside ends as required in a boiler of the locomotive type, but that the staybolts in that portion of the tube sheets containing the tubes should be hollow or drilled at both ends as required for the waterlegs of water-tube boilers.

Case No. 313

Inquiry: Is it permissible, under the requirements of Par. 186 of the Boiler Code, to join by autogenous or fusion welding the butting edges of flanged plates to form the waterlegs of detached smokeless fireboxes, where the stress due to the steam pressure is fully carried by staybolting?

Reply: The welded construction described is allowable under the rules of the Code provided the strength of the structure is sufficient to meet the Code Rules without making any allowance for the holding power of the weld.

Case No. 318

Inquiry: Is it permissible, under Par. 331 of the Boiler Code, to omit the stamping from completed shells of miniature boilers which are formed by a cupping or hot-drawing process in which the stamping is necessarily obliterated?

Reply: It is the opinion of the Committee that the intent of Par. 331 would be met if a record of the heat numbers taken from the plates were checked with the mill test reports, and if found to meet the Code requirements, the inspector may authorize the manufacturer to proceed with cupping the plates, after which the manufacturer is to stamp the shell, in the presence of the inspector, with a lot number which will identify the sheet with the test sheet record.

Case No. 322

Inquiry: What material is it necessary to use under the requirements of the Boiler Code for the Y-fitting, also for the safety-valve body, for safety valves to be operated at a pressure of 225 lb.? May cast iron be used for this purpose?

Reply: Under the requirement of Par. 9 it is necessary that the Y-fitting be constructed of steel, but the safety-valve body need not be of steel unless to operate with superheated steam (see Par. 289).

Case No. 323

Inquiry: Does Par. 380 cover all classes of lap-seam boilers including boilers of the locomotive type, or does it apply solely to h.r.t. boilers? Is it the intent of the Boiler Code that the drums of water-tube boilers over 36 in. in diameter and over 20 years of age come under the requirements of Par. 380?

Reply: It was the intent of the Committee that the application of Par. 380 should be limited to h.r.t. and similar types of fire-tube boilers, the shells of which are exposed to the fire or products of combustion. It was not intended that Par. 380 should apply to the drums of water-tube boilers, or boilers of the locomotive type.

Case No. 324

(In the hands of the Committee)

Case No. 325

Inquiry: Is it necessary in existing installations that, under the requirements of Par. 315, the feedwater delivery pipe shall be carried through the shell of an h.r.t. boiler near the front end in all cases? With scale-forming water it is found that with the delivery pipes carried through the shell near the back end, they could be easily removed for cleaning out scale, etc.

Reply: Attention is called to the fact that Par. 315 appears in Part I, Section I, of the Boiler Code and therefore does not apply to existing installations.

Case No. 326

(Annulled)

Case No. 327

Inquiry: Is it necessary, under Par. 430d, that the fusible plug must be located in a tube not less than one-third the length of the tube above the lower tube sheet where such a boiler is fitted with an extra head and a water-heating compartment at the top of the shell?

Reply: It is the opinion of the Committee that where a top compartment is utilized for preheating of feedwater, the measurement of the tube may be construed as applying to that portion of the tube between the firebox tube sheet and the point where the tube enters the top compartment.

Case No. 328

(In the hands of the Committee)

Case No. 329

Inquiry: What tensile strength shall be used for the calculation of the maximum allowable working pressure of pressure parts formed of steel castings of Class B grade or of seamless steel tubing material?

Reply: It is the opinion of the Committee that the tensile strength used in the calculation of pressure parts formed of steel castings of Class B grade or of seamless steel tubing shall be the minimum tensile strength determined from tests made on the test specimens located and taken as given in Par. 88 of the Code.

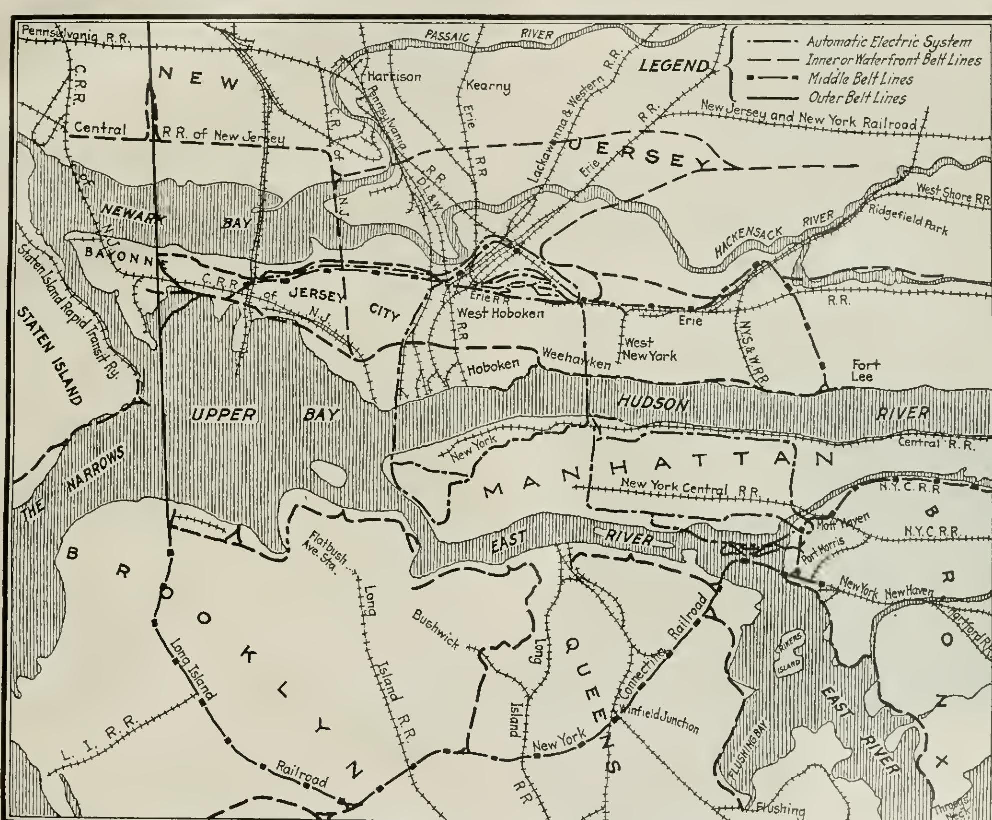
Case No. 330

Inquiry: Is it permissible to repair cracks in the tube sheets of water-tube boilers by autogenous or fusion welding? In the recommendations in the Appendix it is stated that no welding shall be allowed in cracks in shell plates or other plates subject to tensile strain, yet it is stated that where tube sheets of boilers have deteriorated not to exceed 25 per cent of their original thickness, the same may be reinforced and repaired by any process of autogenous welding.

Reply: It is the opinion of the Committee that such process of reinforcing and repairing may only be used on tube sheets which are not subject to tensile strain, as permitted by the Appendix.

New York, New Jersey Port and Harbor Development Commission should be of great interest to engineers. Briefly the recommendations of the Commission are as follows:

1 Adoption of a compact between the states of New York and New Jersey providing for the creation of a single port district administered by a single port authority
2 Construction of an automatic electric system connecting the



Map Showing Proposed Belt Lines and Automatic Electric System

trunk-line railroads with terminal stations in Manhattan for the distribution and collection of general merchandise, freight, and food products
3 Development of a standard belt-line railroad system for all parts of the port except Manhattan, embracing inner or waterfront belt lines in New York and New Jersey, middle belt lines in New York and New Jersey, and an outer belt line in New Jersey
4 Consolidation of railroad marine operation not eliminated by the automatic electric and extended rail service, with separate joint railhead terminals for car-float service and lighterage.

Further recommendations are made concerning food-receiving stations and terminal markets in Manhattan and the Bronx, provision of waterfront piers, warehouse facilities, dredging of channel, modifying bridges, zoning of steamship terminals by trade routes, from Manhattan Island itself. This problem is complicated by the need for eliminating the New York Central tracks at the grade on the west side of Manhattan and the congestion which prevents the bringing of freight cars to the sidings of the shipper and consignee.

Before reaching its final decision, the Commission gave careful consideration to:

a Railroads for standard rolling stock, both elevated and below ground
b Motor-truck service between New York and New Jersey similar to the Cincinnati trap-car system
c Cableway truck-conveyor system
d Improved water transfer service.

The plan evolved will release the Hudson River and New Jersey waterfronts from pier-station occupancy, will dispose of the New York Central's surface tracks, will provide ample capacity for the future and effect a large saving in terminal cost. This system, known as the Automatic Electric, will resemble a railroad but will function as a conveyor, electric circuits being used to hold the trains in fixed position with respect to each other. The elements of the systems are a belt-line railroad in New Jersey reaching all

Recent Hydraulic Development on the Pacific Coast

Robert Sibley

Ever since the announcement was made at the Pasadena Convention of the National Electric Light Association by the Water Power Development Committee last spring that a program of expenditure amounting to $700,000,000 must be put under way immediately in the West for a ten-year development period, there has been a considerable stir throughout the nation in following the Pacific Coast situation. The year just brought to a close has seen more than this program outlined put into operation. Below is a summary of the present status of this work. The report of the California Railroad Commission shows that this state alone has issued some $60,000,000 in hydraulic securities during the past year under the approval of the Railroad Commission.

It is interesting to note some of the outstanding features of this development, as a number of records are being established. At the Kern River No. 3 power plant of the Southern California Edison Company are being installed two Pelton reaction turbines of 23,500 hp. capacity operating under a head of 802 ft. On the Pit River development of the Pacific Gas and Electric Company are being installed two 40,000-hp. turbine units of the Allis-Chalmers design. The Great Western Power Company in its Caribou plant is putting into service this month transmission of hydroelectric energy at 165,000 volts over a distance of 190 miles. Both the Pacific Gas and Electric Company and the Southern California Edison Company have under way the installation of 220,000-volt long-distance transmission. The copper for the Pit River development of the Pacific Gas and Electric Company, which is to operate at 220,000 volts, has recently been ordered from the Anaconda Copper Mining Company of Great Falls, Mont. The finished cable will have a 500,000-circular mil cross-section made up of seven conductors, seven-rope lay strand, and it is the largest rope strand which the company has had to build. Something over ten million pounds of copper will be required and it will require approximately two hundred freight cars or about eight average-size freight trains to haul the finished order.

It is impossible to go into detail in a brief sketch such as this in regard to the many interesting features, or even to outline the gigantic power program that is under way in the West. A general conception of its magnitude, however, may be gleaned from the fact that the Southern California Edison Company in its sworn statement before the California Railroad Commission states that it will complete its Big Creek development within the next fifteen years, developing a total of something over 800,000 hp. at a cost of $200,000,000. This energy is to be transmitted into Los Angeles at a distance of 240 miles over a 220,000-volt circuit. The company is now under active construction of this program and the first units in this new development will be put into commission during the current year. This same company has quite recently made announcement of the taking out of water rights on the Colorado River which will necessitate the building of a dam 500 ft. high and which will bring about the storage of 40,000,000 acre-feet. As the largest storage reservoir in the western hemisphere now stores but something like 2,600,000 acre-feet, being that of the Elephant Butte Dam in New Mexico, it is readily seen to what gigantic proportions such a development may arrive. The conservation of this water will bring about the development of 4,200,000 hp. By leaving out the Grand Canyon of the Colorado, the company expects to develop 2,500,000 hp.

The four principal companies that are now under active operation in development work in California are: The Southern California Edison Company, The Pacific Gas and Electric Company, The Great Western Power Company and the San Joaquin Light and Power Corporation, in addition to the work of the city of San Francisco and the city of Los Angeles.

The accompanying tabulation gives brief particulars regarding the outstanding features of the present development. It does not, however, give the completed capacity of all the plants that are in the proposed schedule of development, but only those that are actually now under way in construction.

ELECTRIC PLANTS UNDER CONSTRUCTION IN CALIFORNIA

Plants	Capacity in Kw.	Type	Expected Date of Completion
Great Western Power Co.:			
Caribou: Feather River (2 units)	40,000	Hydro	Apr. 1921
Pacific Gas and Electric Co.:			
Oakland	12,500	Steam	Jan. 1921
Hat Creek No. 1	6,100	Hydro	Apr. 1921
Hat Creek No. 2	8,200	Hydro	Apr. 1921
Fall River	44,300	Hydro	Mar. 1922
Spring Gap: Stanislaus River	7,500	Hydro	July 1921
City of San Francisco:			
Moccasin Creek (3 units)	49,500	Hydro	Jan. 1923
Southern California Edison Co.:			
Big Creek No. 2: 3d unit	16,500	Hydro	Dec. 1920
Kern River No. 3	30,000	Hydro	Feb. 1921[1]
Big Creek No. 8	22,500	Hydro	Aug. 1921
San Joaquin Light and Power Corpn.:			
Midway	12,500	Steam[2]	Apr. 1921
Kern River	8,250	Hydro	July 1921
Southern Sierras Power Co.:			
Owens Auxiliary	2,500	Hydro	Feb. 1921
Levining Creek	2,500	Hydro	Oct. 1922
Los Angeles Gas and Electric Corpn.:			
Los Angeles	10,000[3]	Steam	Jan. 1921
City of Los Angeles:			
San Fernando	7,000	Hydro	Jan. 1921
Franklin Canyon	2,500	Hydro	Jan. 1921
Total	289,850		

[1] First unit. [2] Gas fuel. [3] Limited to 7500 kw. on account of boilers.

The power shortage in California seems to be unabated, even though new developments have been put in during the past year. It would seem that the growth of the state, proceeding at the rate of about 44 per cent during the ten-year period, is bringing about such increased agricultural and industrial development that the power program will need exerted upon it all the energy possible in the way of financial support in order to satisfy the insistent demand for power on all sides. A great effort is being made throughout California and the West to put the problem before the public itself in order that it may see the necessity of backing up the various utility companies in their efforts to acquire the necessary financing that this program may go ahead unhampered.

Robert Sibley.

San Francisco, Cal.

Chordal's letters, written in the days of the contract system, tell how the Yankee contractor "Doolittle" produced remarkable results in the Western engine shop of "Pete and Cady." "Doolittle sails in," says the account. "The engine work is in his hands; the men are his. He pays them. He stops every man of them and sets them to work on tools, fixtures, jigs, etc., and keeps them there for a month. Doolittle goes through every piece and cuts the price down and the men's earnings up."

This is an optimistic view so far as the men are concerned. In too many cases the contractor adopted sweatshop methods and cut the men's earnings *down*. The real rub, however, is explained by Chordal, who intimates that Pete and Cady felt a bit sore at the profits Doolittle was making. They exclaimed: "We would think we were going to the dogs if we paid a superintendent the money as salary which Doolittle the contractor gets as profit."

In an article on Labor as a Business, Not a Commodity, in the *Manufacturers Record*, by George H. Cushing, Washington representative of the American Wholesale Coal Association, another scheme for contracting for labor is set forth which at least has the advantage of removing the objections to the older scheme which were due to the letting of contracts to individuals. It is, instead, to let the contract for labor to the men as a body, both manufacturer or operator (he is speaking of coal mining) and the contractor being incorporated and equally responsible under the law. For example:

> The coal-mine operator has, we will say, a proved productive capacity of 100,000 tons per month. He sells on contract 60 per cent of that output, or 60,000 tons per month. He can—with the same safety he moves in other directions—sign a contract for the labor to produce 60,000 tons a month. That is, he can, to that extent, contract with his men to give them that measure of a minimum wage and a minimum working time...... The operator, having received the labor as a unit, should pay for it as a unit. That is, only one pay check should pass. The employing company should pay the employee company for the labor even as it pays any other business house for its product. The employee company should distribute its own funds.

Mr. Cushing contends that "labor is *not a commodity*...... it is an act of production. Production is a business. For that reason, labor is a business. The main difficulty is that labor has not been organized—as a business." He holds, however, that labor is generally regarded as a commodity to be bought in the open market at the lowest price, the same as machinery or any other commodity is bought. While acting on that theory capital has paid labor for results only, often on the piece-work basis, and soon after came the cuts in piece-work rates and the many other points of contention that have given rise to so much strife. He says:

> Labor felt outraged. It believed that it was tricked. Perhaps it was. Even so, it had no different treatment than was customarily given to other producers of raw material. Instead of organizing for business defense as other producers had done, labor organized a voluntary union to fight it out along lines of reprisal. So labor came to stand firmly against any proposal to accept payment for results only. It demanded payment for time spent, regardless of results. Thus the issue was drawn. Labor demanded payment for time spent only. Capital offered to pay for results only. The two could not possibly have maneuvered themselves into positions farther apart. And each side began to organize its forces to impress its view upon the other. This building of competing organizations has been going on for 40 years. The organized movements on both sides have taken on a variety of names, but the animating purpose on both sides has remained constant.

With the sudden collapse of the tremendous demand for workers and the state of flux into which labor has lately been thrown, Mr. Cushing believes that the time is ripe for a new deal—perhaps a new labor organization, not a replica of the old, built upon hatred and with a lack of principles, but an organization built along business lines; and that labor will go into business as, incidentally, he says, it should have done 25 years ago. Perhaps labor will be organized "as a business" instead of remaining simply a "commodity."

to the English debenture holder who says: "I do not want big profits; I want an assured rate of interest with absolute security. I would rather have a sure 4 per cent or $4^1/_2$ per cent than I would the ordinary shares with a possible 10 per cent or a possible nothing; therefore, give me debenture."

National Board of Boiler and Pressure Vessel Inspectors

The first annual meeting of the National Board of Boiler and Pressure Vessel Inspectors brought together at the Hotel Statler in Detroit on February 2, 3 and 4 a group of about sixty men, including members of the Board itself, members of the Boiler Code Committee of The American Society of Mechanical Engineers, and others interested.

The first day was devoted to the hearing of addresses. Dr. D. S. Jacobus, acting chairman of the A.S.M.E. Boiler Code Committee, told of the genesis and development of the Code, emphasizing the fact that no action had been taken without consideration of the interests of all who were involved in the questions under discussion.

Charles E. Gorton, chairman of the American Uniform Boiler Law Society, told of the appointment of the first Boiler Code Committee by Col. E. D. Meier, when he was president of The American Society of Mechanical Engineers, how the Society had reached the limit of its functions in the formulation and interpretation of the Code, and the Uniform Boiler Law Society had been organized to promulgate it, and how the National Board of Boiler and Pressure Vessel Inspectors had been organized at the instigation of the American Uniform Boiler Law Society. He told of seeing on his recent trip to the Coast a boiler with the stamps of 22 different states upon it, which absurd practice, now not uncommon, would be avoided by the facilities and simple procedure offered by the organization of the National Board.

Of the other speakers E. R. Fish, vice-president of the Heine Safety Boiler Company, explained still further the advantage of a single stamp for boilers constructed in accordance with the Code. S. F. Jeter, chief engineer of the Hartford Steam Boiler Inspection and Insurance Company, spoke upon the advantages of uniform qualifications for boiler inspectors. F. R. Low, editor of *Power*, outlined some of the possibilities, opportunities and responsibilities before the National Board.

J. C. McCabe, commissioner of the city of Detroit, and chief inspector of boilers for the state of Michigan, spoke of the qualifications and duties of boiler inspectors.

On the second day the members of the Board attended a meeting and took part in the deliberations of the Boiler Code Committee of The American Society of Mechanical Engineers. This meeting of the Committee was held at Detroit instead of, as usual, at the headquarters of the Society in New York, in order to give the Committee the advantage of meeting and counseling with the men from all over the country who are enforcing the Code. Nineteen inspectors were present from almost as many different states in widely separated sections of the country.

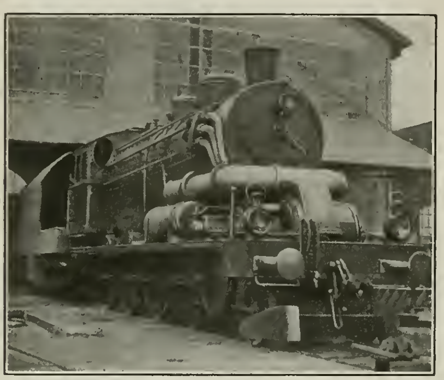
The objects of the Board of Boiler and Pressure Vessel Inspectors as stated in the Constitution adopted are as follows:

> To promote uniform boiler laws and rules throughout the jurisdiction of its members.
>
> To secure uniform approval of specific designs of boilers and other pressure vessels, as well as appurtenances and devices used in connection with their safe operation.
>
> To promote one uniform code of rules and one standard stamp to be placed upon all boilers constructed in accordance with the requirements of that code, and one standard of qualifications and examinations for inspectors who are to enforce the requirements of said code.
>
> To compile official statistics and other data.

Steam-Turbine Locomotive

When William Avery (who, by the way, was a relative of the late John E. Sweet) built his Hero reaction steam turbines nearly ninety years ago and used them for operating sawmills and woodworking shops in New York State and elsewhere, he took a chance at trying out one for the motive power of a locomotive on the Newark, N. J., meadows. Mr. Sweet has described the turbine as having a 7-ft. arm which rotated at enormous velocity and had a speed at its tips of 14½ miles per minute. It is not surprising that the machine ended its life in a ditch beside the track.

From that day to this there has been comparatively little effort to apply the steam turbine to locomotives. According to the *Railway Gazette* of London, however, a turbine-driven locomotive is now being tried on the Swiss Federal Railways. It is converted from a standard 4-6-0 type as used on the Federal Railways. The



Experimental Turbine Locomotive, Swiss Federal Railways

turbine is reversible and is placed in front of the smokebox, power being transmitted by 30 to 1 gearing to a horizontal crankshaft placed above the leading truck, the rods of the six coupled wheels being extended forward and connecting with the crankpin at each end of the crankshaft.

The engine is designed for a turbine speed of 8000 r.p.m., giving a running speed of 49 miles an hour. The boiler is equipped with a superheater and a condenser is fitted below it, utilizing water from the tender, to which latter it is returned for cooling by being allowed to fall in narrow streams from the roof extending over the tender, which is designed for the purpose. As there is no blast nozzle an air draft through ventilators is used for maintaining the required action on the fire, in conjunction with a blower. It is claimed that while making the trial trips the engine has shown a fuel economy 25 per cent under that of the compound locomotives in service, while it runs very smoothly at high speeds, this being accounted for by the reduction of the reciprocating parts. The special equipment was designed by Mr. Zoelly, of Escher Wyss and Company, Zurich, and applied to the locomotive at the Swiss Locomotive Works at Winterthur.

Rankine the Man

Back of the editor's desk in the editorial rooms of Mechanical Engineering hangs a finely executed portrait of Prof. William J. M. Rankine, whose textbooks on the steam engine and applied mechanics have thrown consternation into the hearts of many aspirants to the degree of M.E. in our technical schools, but who in after years have blessed the days of rigorous training prescribed by this master of engineering mathematics.

It may relieve the minds of some to learn what apparently is not well known, that Rankine was not only a profound technologist who delighted in disciplining the youthful mind, but he also was a humorist and a many-sided man.

A short time ago Mr. Frank E. Law, former chairman of the Finance Committee of the A.S.M.E., sat under the above-mentioned portrait in the editorial rooms and recited a humorous poem entitled The Mathematician in Love. Rankine's eyes appeared to twinkle, whereupon Mr. Law said that no other than Rankine himself had written it, and many more just as good.

Since then a letter received from Mr. Law gives the following interesting bits of information:

> Referring to our conversation today, the article on Rankine in the Encyclopaedia Britannica, Eleventh Edition, Vol. XXII, page 894, says,—after referring to Rankine's contributions to technical journals and to his textbooks—"These writings, however, corresponded to but one phase of Rankine's energy and many-sided character. He was an enthusiastic and most useful leader of the volunteer movement from its beginning, and a writer, composer and singer of humorous and patriotic songs, some of which, as 'The Three Foot Rule' and 'They Never shall have Gibraltar,' became well known far beyond the circle of his acquaintance."
>
> I think you would do a real service in calling attention to this human quality in Rankine. Most think of him only as a dry-as-dust writer.
>
> The Encyclopaedia article speaks of Rankine's Scientific Papers, published in London, 1881, and says the volume contains a memoir of Rankine by Prof. P. G. Tait. This memoir would doubtless supply many interesting details.

Industrial Disputes in Canada

The establishment of the industrial courts in Kansas less than a year ago has brought very forcibly to public notice the part the Government plays in the maintenance of operation of essential industry. Canada recognized the need for action and in 1907 Parliament enacted the Industrial Disputes Investigation Act for aid in the prevention and settlement of strikes and lockouts. This act, commonly known as the Lemieux Law, has been amended from time to time and as at present in force may be briefly outlined as follows:

Wherever a dispute arises between the employer and any of his employees, either of the parties may apply to the Minister of Labor for the appointment of a Board of Conciliation and Investigation consisting of three members appointed by the Minister. One of these shall be appointed on the recommendation of the employer, one on the recommendation of the employees, and the third on the recommendation of the members previously chosen. The Board holds office until its final report is placed in the hands of the Minister of Labor. The Minister is given discretion in the granting of an application for the appointment of a board, but after being appointed no court proceedings may be held to question the establishment of a board or its proceedings. The Board is charged with careful inquiry into the dispute and all matters affecting its merits and right settlement. It is given latitude in making suggestions that will induce the parties to the dispute to come to a fair and amicable settlement, and if a settlement is reached it is as binding as any recommendation of the Board. In case the Board cannot settle the dispute, a full report is made to the Labor Minister setting forth the evidence and making recommendation for its settlement according to the merits and substantial justice of the case. The Board is empowered to force the attendance of witnesses and administer oaths and it can require that books, papers and documents be produced for its investigation. Fines are prescribed for persons guilty of contempt of the Board. The proceedings of the Board may be conducted in public at its discretion, and if necessary it may employ experts to advise on technical matters. The members of the Board are paid at a per diem rate plus actual traveling expenses.

Strikes and lockouts prior to and pending the reference of dispute to the Board of Conciliation and Investigation are declared illegal, and both employer and employees must give at least thirty days' notice of any intended change affecting conditions of employment with respect to wages or hours. Penalties are provided for strikes and lockouts contrary to the provisions of this law. In some cases where the Minister of Labor discovers that a strike or lockout is imminent he may initiate action in the formation of a Board without application from any interested party. Some special treatment is authorized in case railroads or municipalities are parties to a dispute.

The Lemieux Law as outlined does not prohibit strikes or lockouts, merely insuring their consideration by an arbitration body.

The formation of the Board will tend to bring the parties in

firm step in the stabilization of the industry.

What may be accomplished by such arbitration as that conducted under the Lemieux Law is shown by the following figures:

Out of 323 disputes affecting mines, transportation, public utilities and war work referred under the Act from the time of its enactment until March 31, 1919, 300 were settled by arbitration, only 23 strikes taking place. From April 1, 1918, to March 31, 1919, there were only two strikes out of 75 disputes. Equally encouraging figures are given for 1920. On December 31, 1920, there were on record but four strikes, affecting 379 people. The Lemieux Law is proving itself to be a most effective means for establishing industrial peace.

News of Other Societies

American Institute of Electrical Engineers

Meeting at Akron and Cleveland, January 14. Sub-Committee on the Rubber Industry, of the Industrial and Domestic Power Committee, presented paper on Application of Electric Power in the Rubber Industry. A report of the committee on coördination of institute activities included a recommendation that the policy be established of awarding prizes for the most worthy papers presented before the institute. The board of directors approved the recommendation in principle and referred the matter back to the committee for the purpose of formulating a plan of procedure.

Society of Automotive Engineers

Meeting in New York, January—during the automobile show. At a session devoted to fuels, ways and means were discussed for improving the automobile engine so as to make the fuel supply last longer. Abstracts of five of the papers presented at this session are given in the Survey Section in this issue. An aviation session was held at which difference of opinion developed as to the advisability of using large, multi-motored planes, or smaller planes with single motors. It was subsequently agreed that the design of the plane depends entirely on the service required as to distance, loads and the character of the country over which the flight is made. Among the aviation papers were: Propellers, by F. W. Caldwell; Design Requirements of Commercial Aviation, by Grover C. Loening; Airplane Wings, by C. D. Hanscom; Commercial Aviation, by Glenn L. Martin; and Compression Pressures and Engine Performance, by S. W. Sparrow.

American Society of Civil Engineers

Annual Meeting in New York, January 19 and 20. Attention was chiefly centered in the election of officers as follows: George S. Webster, Philadelphia, president; Andrew M. Hunt, New York, and Edward E. Wall, St. Louis, Mo., vice-presidents; and O. E. Hovey, New York, treasurer. The committee on stresses in track supplemented its elaborate report of last year by giving details of tests and experiments conducted to demonstrate the effect of curves on the stress in the rail, and the action on the track of flat spots in wheels. Other special committees also presented reports. It was determined that the board of direction should act as a committee to decide on matters affecting the relations of the society with other technical organizations. Under this arrangement the board will keep in touch with the Federated American Engineering Societies and other organizations, and in this way with general activities of interest to engineers.

American Society of Heating and Ventilating Engineers

Annual meeting in Philadelphia, January 26, 27 and 28. Reports were presented by the society's respective committees on code for testing low-pressure heating boilers, on standard code for testing heating systems, on steam and return main sizes, on schoolhouse standards, on standard method for testing air washers, on furnace heating, and on research. A paper by A. B. Reck, of Copenhagen, Denmark, on the influence upon boiler economy of continuous firing with highly volatile fuel without intervening cleaning, is abstracted in the Survey Section in this issue. A theory of dust action developed from investigations carried out of this paper was published in the Survey Section of Mechanical Engineering for February, p. 130. Other technical papers of mechanical engineering interest were: Design of Large Boiler Plants, by J. Grady Rollow; Method of Utilizing Heating Systems for Cooling Rooms in Summer, by A. M. Feldman; Forced Hot-Water Circulation Heating System, by Robert Hughes; Accelerated Hot-Water Systems, by A. J. Wells; Pulverized Coal for Power Plants, by F. A. Scheffler; Briquetted Coal for Household Fuel, by I. H. Kennedy; Economizers, by W. F. Wurster; Transmission of Heat through Single-Frame Double Windows, by A. N. Shaw; and Comparative Tests of Sixteen-Inch Roof Ventilators, by Dryden, Stutz and Heald, of the U. S. Bureau of Standards.

Providence Engineers Consider Transportation

"One of the most important problems in the industrial life of New England is that of efficiently supplying raw material and distributing the finished product. The future prosperity of the country is dependent to a large extent on the ability of the railroads to meet out transportation requirements."

The above words were in the rallying call of the Providence Engineering Society to its Fifth Annual Banquet held February 1, 1921. In addition to addresses by the governor of the state and the mayor of Providence, Prof. William J. Cunningham spoke concerning the Federal Control of Railroads. Professor Cunningham is the James J. Hill Professor of Transportation at Harvard University and has had nearly twenty-five years of practical railroad experience in the traffic, operating and executive departments of various railroads throughout the United States. He pointed out that railway rates could not be increased beyond the point where they would tend to drive traffic away. He criticised the standard of wage rates established throughout the country by the Railroad Administration, and emphasized the fact that increased revenue, increased rates and further operating economies were necessary to make the roads self-supporting. He also decried as a national calamity the public ownership of railroads.

Arthur P. Russell, vice-president of the New York, New Haven & Hartford Railroad, outlined the financial difficulties of the New England railroads and took up the situation of the New Haven road in some detail. In the matter of railroad development he paid specific attention to the problems in Providence and told of plans for increased efficiency that will be derived from improved facilities in the Providence district.

John Fritz Medal for 1921 Awarded to Sir Robert A. Hadfield

At the annual meeting of the John Fritz Medal Board of Award held on January 21, 1921, the John Fritz Medal for 1921 was awarded to Sir Robert A. Hadfield, of London, for the invention of manganese steel. Manganese steel was first described in a paper read by Sir Robert before the International Engineering Congress in 1893. For uses in which toughness combined with great strength is demanded, manganese steel is invaluable. It is non-magnetic and its applications have been many and varied. During the war 9,000,000 Hadfield manganese-steel helmets were used by the English, American and Belgian armies, and at the close of the war the Hadfield helmets were rapidly replacing the French type.

Sir Robert A. Hadfield is one of the leading steel manufacturers of England and was the first to introduce the 48-hour week in his work, putting it into effect 25 years ago. During the war he was one of the largest producers of munitions for the British Navy. Besides manganese steel he invented a magnetic steel of high permeability, especially suitable for use in dynamos and motors; showed that steel containing a small percentage of silicon, after a double heat treatment, was far superior to the purest obtainable iron; and is responsible for other important developments in the steel industry. He has been a prolific technical writer and an energetic promoter of the scientific societies of Great Britain. He is a member of the American Institute of Mining and Metallurgical Engineers and The American Society of Mechanical Engineers, and is one of the greatest users by mail of the Engineering Societies Library.

Marine Electrical Engineering

Discussion of Use of Electricity in Marine Work at Joint Meeting of New York Sections of Electrical and Mechanical Engineers

THE immense tonnage of the American Merchant Marine presents engineering problems of great import. To consider the use of electricity in marine work, the third of the joint meetings of the New York Section of the American Institute of Electrical Engineers and the Metropolitan Section of The American Society of Mechanical Engineers brought together a large, deeply interested audience in the Auditorium of the Engineering Societies Building on the evening of January 28, 1921.

The program of the evening was in charge of Alfred E. Waller, of the Marine Committee of the A.I.E.E. and chief engineer of the Ward Leonard Company.

Admiral W. S. Benson, chairman of the United States Shipping Board, outlined the steps necessary in the development of the American Merchant Marine and emphasized the present slow development of electric power and its application in our naval vessels. He stressed the necessity of meeting foreign competition in the cost of operation of ships. The principal problem in operation is one of fuel, and Admiral Benson insisted on oil rather than a return to the use of coal. He bespoke especially the development of an efficient internal-combustion engine for marine work.

H. L. Hibbard, of the Cutler-Hammer Manufacturing Company, presented a paper on Electricity Applied to Ship Auxiliaries. He outlined the development of the past four or five years and described the design requirements of auxiliaries, emphasizing the specific needs for ventilated and enclosed watertight motors. The various types of control for auxiliaries were also listed and the peculiar characteristics of motors for driving, engine-room auxiliaries, deck machinery and steering gear were treated in some detail. Concerning definite advantages of auxiliaries electrically driven, Mr. Hibbard said:

It has been shown by experience that the electric drive of the auxiliary machinery has resulted in a considerable saving in fuel consumption of a vessel. This applies particularly to vessels using steam for their main propulsion. For ships operated by Diesel engines or Diesel-electric drive it is obviously of great advantage to operate all the engine-room auxiliaries by electricity, as it is largely a question of the efficiency of electric transmission with a large and reliable generating unit against a number of small inefficient oil or steam engines, and it is naturally desired to avoid the generation of steam in any quantity on a motorship.

In the matter of first cost, it is also apparent from such figures as have been available to date that electrical auxiliary machinery is roughly about 20 per cent more expensive than steam, except in case of deck winches where the difference is more, sometimes 100 per cent. It is also found that an oil-engine-propelled motorship is about 30 per cent more expensive in first cost than a steam-driven vessel and that, strange as it may seem, the Diesel-electric-propelled ship is slightly less expensive than the straight Diesel owing to the smaller and higher-speed oil engines which it is possible to utilize.

As against these disadvantages of first cost and weight, are obtained the advantages of:

1 Suppression of heat in spaces adjacent to the gear and transmitting lines, which is of importance in certain cases
2 Elimination of accidents due to freezing and bursting of steam pipes, cylinders, etc.
3 Reduction of vibration and noise and an increase in the habitability of the ships due to these factors. This is particularly marked in the case of the steering gear
4 Simplification and flexibility of control, operation being obtained readily from the most convenient point
5 The obtaining of mechanisms as outlined above which are very much more efficient in operation than the steam equipments. This is the most important consideration.

Another important consideration is the fact that experience shows on motorships already constructed with electrical auxiliaries, that in port the power required during the period that the deck winches are handling the cargo is about three times the amount required with the auxiliaries at sea.

Commander C. S. McDowell, U. S. N., emphasized the need of proper terminals for proper shipping and the necessity for electrifying terminals, giving in detail suggestions as to the electrically operated devices that might be used in terminal operation.

Under the subject of Turbine Reduction Gears versus Electric Propulsion for Ships, Eskil Berg, of the General Electric Company, treated various types of ships and discussed the relative merits of the two types of drives in each case. The following is a résumé of his paper:

The Navy Department, after years of comparative study and having actual operating data on electrically propelled vessels available, has decided to equip all the larger Navy vessels with electric drive. Economical cruising speed can be obtained, machinery can be located in invulnerable places, plurality of generating units can be used, and maneuvering can be accomplished more quickly and accurately.

Geared turbine drive has an advantage in fast destroyers and light cruisers, where the power is large and the propeller speed high. The weight of propelling machinery in this type of vessel is of utmost importance and electric drive, being heavier, cannot be considered.

In merchant ships each individual case must be studied, considering the questions of service, economy, reliability, weight and cost. For fast passenger liners electric drive has an advantage, for transmission efficiency can be made practically equal to double-reduction gearing and a more efficient turbine can be built. Noise is practically eliminated with electric drive.

In moderate-power twin-screw ships of 6000 to 8000 hp., electric drive has a decided advantage both in economy, weight and price if one turbo-generating unit is used to drive both propellers.

In slow-speed single-screw freighters of 2500 to 3000 hp., the geared turbine is somewhat lighter. The actual transmission efficiency of the gears is also better. Considering losses of the reversing turbine, packing losses, and leakage of steam due to larger clearances, the transmission efficiency is in favor of electric drive. If, however, the motor is located aft, doing away with long shafting with its expensive bearings, supports and shaft alleys, the electric drive is the lightest, cheapest and most economical, as well as the most reliable method to use.

In freighters of 1500 hp. or less, geared turbines are lighter and cheaper. As the power is small, a gear can be designed which is less affected by sudden load variation or disalignment caused by springing of the hull or inaccurate workmanship.

In his paper on the Electric Propulsion of Ships, W. E. Thau, of the Westinghouse Electric and Manufacturing Company, discussed various types of power drives and described the installation of the propelling machinery on the U. S. S. *Tennessee*.

In discussing Commander McDowell's paper, R. H. MacLain, of the General Electric Company, stressed the necessity for structural changes in boats to permit more rapid stowing and breaking down of cargo, pointing out that the solution of the freight-handling problem on the Great Lakes was derived from the construction of the boats themselves.

G. A. Pierce, of The William Cramp & Sons Ship and Engine Building Company, in discussing Mr. Berg's paper, pointed out the advantages of the reciprocating engine in naval and coastwise ships. He further emphasized reliability, simplicity and ease of operation as points to be considered in a discussion of the relative merits of mechanical reduction-gear drive versus electric drive.

In a discussion of Mr. Thau's paper Commander Jones of the U. S. S. *Tennessee* testified that the records of the ships now in service show that electric-drive propulsion has established itself. and stated that operating personnel can be successfully trained in a comparatively short time to handle casualties to machinery and apparatus with as much facility as with the older types of propulsion.

Engineering Foundation Endowment

The Engineering Foundation, established in 1914 for the stimulation and support of research in science and engineering, is frequently obliged to refuse to support research projects brought to it because it lacks funds. The Foundation needs a large increase of endowment. Nine donations of $50,000 each are desired so that an offer of $50,000 toward a half-million may be claimed. Gifts to the Foundation are exempt from income tax and each donor of $250,000 or more will be honored as a Founder.

The Foundation is administered under the auspices of the United Engineering Society, American Society of Civil Engineers, American Institute of Mining and Metallurgical Engineers, American Society of Mechanical Engineers and American Institute of Electrical Engineers, by the Engineering Foundation Board, consisting of thirteen representatives of these societies, and three members at large. Alfred D. Flinn, 29 West 39th Street, New York, N. Y., is Secretary and further information may be secured from him.

American Engineering Council in Session at Syracuse, February 14, Elects Executive Secretary of the New Organization—Herbert Hoover Gives Address on Industrial Waste

L. W. Wallace

THE American Engineering Council met at the Hotel Onondaga, Syracuse, N. Y., morning and afternoon, on February 14, for the transaction of business matters relating to the work of The Federated American Engineering Societies. The Council strongly endorsed the model bill on registration of engineers previously prepared by Engineering Council and reported in Mechanical Engineering for December 1920, p. 717. It also approved legislation proposed in connection with the Nolan Patent Bill providing for a reciprocal arrangement with foreign countries to remove discrimination against patents in foreign countries held by American inventors. Announcement was made of the membership of the Federation's Committee on Elimination of Waste in Industry, appointed in accordance with the suggestion of Herbert Hoover that the subject be taken up as one of the major activities of the Federation. The personnel of the Committee is as follows: J. Parke Channing, Chairman; L. W. Wallace, Vice-Chairman; Robert B. Wolf, Chas. E. Knoeppel, Robert Linton, J. H. Williams, Fred. J. Miller, L. P. Alford, Ira N. Hollis, George D. Babcock, Morris L. Cooke, E. E. Hunt, Harrington Emerson, H. R. V. Scheel, and F. G. Coburn. It was voted to recommend to President-Elect Harding that an engineer be appointed on the Interstate Commerce Commission. Before adjournment the next place of meeting of the Council was announced to be Philadelphia.

The most important action at the meeting was the election of L. W Wallace as secretary of The Federated American Engineering Societies. Mr. Wallace has already been serving as treasurer of the Federation and as vice-chairman of its Committee on Industrial Waste. In view of his election as secretary the position of treasurer became vacant and W. W. Varney of Baltimore was elected temporary treasurer.

Mr. Wallace was graduated in mechanical engineering from the Agricultural and Mechanical College of Texas in 1903. He afterward served a railroad apprenticeship and became instructor at Purdue University, then assistant professor of car and locomotive design, and finally, in 1913, head of the department of railway and industrial management, which position he held until 1917. He received the degree of M.E. from Purdue in 1912. Upon leaving the university he became assistant general manager of the Diamond Chain and Manufacturing Company, Indianapolis, Ind. At the close of the war, when the Red Cross Institute was established at Baltimore for the purpose of giving vocational training to blind soldiers, Mr. Wallace left Indianapolis to become director of the Institute and conducted the work until last January, when he was elected treasurer of The Federated American Engineering Societies.

In the conduct of his many activities he had displayed breadth of vision and has been actuated by altruistic motives, characteristics which, combined with an executive experience and a deep interest in the principles of management, admirably adapt him for the work he is to undertake. In various addresses on the subject of industrial management before The American Society of Mechanical Engineers and elsewhere he has shown insight into the fundamentals underlying industrial unrest and a sympathetic appreciation of the rights as well as the responsibilities of employee and employer. This latter will be a most favorable asset to Mr. Wallace in conducting the important investigation dealing with the elimination of waste in industry which is to be undertaken by the Federation.

Address on Industrial Waste by Herbert Hoover

In addressing the American Engineering Council of the F.A.E.S., Mr. Hoover said the Federation is in a position of disinterested service and wants nothing from the public, either individually or as a group. It has initiated services to the public in many directions. One of these is the preliminary survey of some of the weaknesses in our production system, recently organized by the Council. Mr. Hoover directed his attention mainly to an outline of these weaknesses, with suggestions of ways and means for increasing production and improving industrial relations. In concluding he said, "We do not believe it is necessary to effect those things by the Government. The spirit of coöperation that has been growing in our country during the last thirty years has already solved many things; it has standardized some things and is ripe for initiative toward coöperation of a widespread character. The leadership of our Federal Government is bringing together the forces as needed. No greater field of service exists than the stimulation of such coöperation. The first step is sane analysis of weakness and sober proposal of remedy. If the facts can be established to an intelligent people such as ours, action is certain even if it be slow. Our engineers are in unique position for this service, and it is your obligation to carry it forward."

An abstract of Mr. Hoover's summary of the most important elements in industrial waste is given below:

The waste in our production is measured by the unemployment, the lost time due to labor conflict, the losses in labor turnover, the failure to secure maximum production of the individual due either to misfit or lack of interest. Beyond this again is a wide area of waste in the poor coördination of great industries, the failures in transportation, coal and power supplies which reecho daily to interrupt the steady operation of industry. There are again such other wastes due to lack of standardization, to speculation, to mismanagement, to inefficient national equipment and a hundred other causes. There is a certain proof of deficient production by comparisons of our intense results in 1918, when, with 20 per cent of our man power withdrawn into the army, we yet produced 20 per cent more commodities than we are doing today. We are probably not producing more than 60 or 70 per cent of our capacity.

No one will ever suppose that it is ever possible to bring national productivity up to the full 100 per cent, but the whole basis of national progress, of an increased standard of living, of better human relations, indeed, of the advancement of civilization, depends upon the continuous improvement in productivity. While we currently assume that great advances in living standards are brought about by new and basic inventions, yet in fact even a greater field of increasing standard lies in the steady elimination of these wastes. The primary duty of organized society is to enlarge the lives and increase the standards of living of all the people—not of any special class whatever. We are therefore proposing to make a preliminary examination of the volume of waste in certain industries, the proportions that lie in each field of fault. And no engineering report is worth the paper it is written upon without constructive suggestions in remedy.

There is ofttimes a superficial dismissal of this subject of maximum production on the assumption that there are positive limits in production due to oversupply. Such assumption has no proper foundation in the broad view of industry as a whole. Too much economic thought on production has delimited its boundaries by the immediated volume of demand of a given commodity. There is no such thing as the nation overproducing, if it produces the right commodities. The commodities or services produced by the whole nation are capable of absorption by the whole nation if they are of the right character. When ten men or one hundred million men divide their united output, they can by doubling their output have twice the amount to divide. The problem in doubling output is to direct it to commodities or services that they can use. There is no limit to the increase of living standards except the limitations of human strain, scientific discovery, mechanical invention and natural resources.

It is true enough that any particular commodity or service can be overproduced, for each will reach a saturation point in demand when all the members of the community have been supplied. The absorption of increased productivity lies in the conversion of luxuries of today into necessities of tomorrow, and to spread these through the whole population by stimulation of habit and education. Wheat bread, railways, good roads, electricity, telephones, telegraphs, automobiles and movies were once luxuries. They are still luxuries to some parts of the population.

It is but a corollary that certain commodities can better be produced for exchange for commodities from outside our boundaries of more appro-

(*Continued on page 219*)

Engineering and Industrial Standardization

Standardization of Elevators

In the December 1920 issue of Mechanical Engineering an announcement was made of the calling of a conference on the Standardization of Elevators. As a result of this conference the American Institute of Architects, The American Institute of Electrical Engineers and The American Society of Mechanical Engineers were invited by the American Engineering Standards Committee to act as joint sponsor for this standardization project.

These societies have accepted this sponsorship and have formed the Sectional Committee which held its organization meeting on February 15. The members of this committee and the organization which they represent are listed below:

S. F. Voorhees and R. H. Shreve, American Institute of Architects
W. W. Chapin and Paul M. Lincoln, American Institute of Electrical Engineers
W. S. Atkinson, and (to be appointed) The American Society of Mechanical Engineers
B. Jones, joint appointee of three Sponsors
I. N. Haughton, N. O. Lindstrom, C. Reedy, H. F. Gurney and H. A. Pratt, Elevator Manufacturers Association of New York
R. P. Miller, American Institute of Consulting Engineers
S. F. Holtzman, American Society of Civil Engineers
D. E. Lindquist, American Society of Safety Engineers
H. L. Whittemore, Bureau of Standards, Department of Commerce
R. D. Spalding, Bureau of Yards and Docks, Navy Department
Capt. A. B. Fry, Office of Supervising Architect, Treasury Department
T. E. Barnum and W. H. Patterson, Electric Power Club
W. W. Lighthipe and, National Association of Building Owners and Managers
C. M. Hansen, National Association of Manufacturers
R. P. Miller, Building Officials' Conference.

Specifications and Codes Submitted to American Engineering Standards Committee for Approval

Three A.S.T.M. Specifications. The American Society for Testing Materials has submitted the following specifications to the American Engineering Standards Committee for approval as Tentative American Standards:

Standard Test for Toughness of Rock
Standard Method for Distillation of Bituminous Materials Suitable for Road Treatment
Standard Method for Sampling Coal.

These specifications may be found in the 1918 volume of A.S.T.M. Standards. Copies may also be obtained from the American Engineering Standards Committee, 29 West 39th Street, New York City.

National Electrical Code. The National Fire Protection Association has submitted its Regulations of the National Board of Fire Underwriters for Electric Wiring and Apparatus, edition of 1920, frequently referred to as the National Electric Code, to the American Engineering Standards Committee for approval as an American Standard. Copies of the Code may be obtained from the National Board of Fire Underwriters, 76 William Street, New York, or from the American Engineering Standards Committee, 29 West 39th Street, New York.

Mining Specifications. The Bureau of Mines has brought three of its publications to the attention of the American Engineering Standards Committee for consideration as Tentative American Standards. They are:

Permissible Portable Electric Mine Lamps (Schedule 6A)
Specification for Storage-Battery Locomotives (Schedule 15)
Suggested Safety Rules for Installing and Using Electric Equipment in Bituminous Coal Mines (Technical Paper 138)

Copies of these specifications may be obtained from the Bureau of Mines, Washington, D. C., or from the American Engineering Standards Committee, 29 West 39th Street, New York.

These specifications and codes are submitted for consideration in accordance with the special provision in the procedure of the Committee, under which important specifications in existence prior to 1920 may be approved without going through the regular process followed in new work. The Committee would be very glad to learn from those interested of the extent to which they make use of these specifications and rules, and to receive any other information regarding them in meeting the needs of the industry.

Cement Specifications. Complete agreement has been reached on specifications and tests for portland cement, so there is now one specification covering both commercial and governmental use. The revised specifications, which were agreed upon by Committee C-1 of the American Society for Testing Materials and the Government Departmental Committee on Cement, have also received the approval of the American Engineering Standards Committee. Copies may be obtained from this committee or from the American Society for Testing Materials.

Recent Foreign Engineering Standards

Copies of the following engineering standards, issued in 1920 by foreign national standardizing bodies, are on file with the American Engineering Standards Committee:

British Engineering Standards Association:
No. 1 Rolled Steel Sections for Structural Purposes, Lists of
No. 12 Portland Cement, Specification for
No. 94 Watertight Glands for Electric Cables, Specification for
No. 97 Watertight Fittings for Incandescent Electric Lamps, Specification for
No. 100 Body Spaces and Frame Ends for Chassis for Private Automobiles, Dimensions for
No. 106 Electrically Heated Cooking Range, Specification for
No. 122 Milling Cutters and Reamers, Standards for
No. 131 Notched Bar Test Pieces, Forms of

Canadian Engineering Standards Association:
No. 1 Steel Railway Bridges, Standard Specification for

Association Belge de Standardisation (Belgium):
No. 1 Construction of Metal Framework, Rules for
No. 2 Construction of Metal Tanks, Rules for
No. 3 Construction of Coverings and Partitions of Corrugated Galvanized Sheet Iron, Rules for
No. 4 Shafts and Transmission Pulleys, Standardization of
No. 5 Construction of Metal Bridges, Rules for.

Hoofdcommissie voor de Normalisatie in Nederland (Holland):
N–19 Compression Couplings
N–20 Flange Couplings
N–29 Loose Collars for General Construction
N–30 Loose Collars for Mill Gearing.

Normenausschuss der Deutschen Industrie (Germany):
DIN–187 Angle Arm for Fixed Bearings for Transmission Shafting
DIN–475 Widths of Spanner Jaws.

Commission de Normalisation du VSM (Switzerland):
VSM–10300 to VSM–10307 Technical Drawings—Oblique Script; Size of Letters; Graphic Presentation of Screw; Cross-Sections
VSM–12050 Whitworth Screw Threads; General Data
VSM–33900 to VSM–33914 "Sulzer" Attachment for Milling Cutters.

Sveriges Maskinindustriförening (Sweden):
SMS–1 Size for Standard Sheet
SMS–2 Metric Screw-Thread System
SMS–3 Whitworth Screw-Thread System
SMS–5 Hexagonal Nuts—Type B6M–BSW Screw-Thread System
SMS–7 Finished Hexagonal Screws—Type B6S–BSW Screw-Thread System
SMS–8 Series of Standard Diameters.

Photostatic copies of these standards can be furnished at a nominal cost, or the copies on file may be consulted at the offices of the American Engineering Standards Committee, 29 West 39th Street, New York.

Standardization of Wires and Cables

At a recent conference called by the American Engineering Standards Committee at the instance of the American Railway Engineering Association and attended by representatives of 14 national organizations, it was unanimously decided that the unification of specifications for wires and cables for other than telephone and telegraph use should be undertaken under one general plan, covering substantially all the more important uses. The proposed work, it is stated, will be carried out under the auspices and rules of procedure of the American Engineering Standards Committee.

Aeroplane Structural Design; a book for designers, draughtsmen and students. By T. H. Jones and J. D. Frier. Sir Isaac Pitman & Sons, Ltd., New York, 1920. Cloth, 6 × 8 in., 267 pp., plates, tables, charts, diagrams, $7.50.

Although several valuable treatises exist dealing with the problems of sustentation, stability and aerodynamics generally, the authors feel a need for a book treating the structural strength of the aeroplane, in which the loading of it and the methods of estimating its strength under load are discussed definitely and practically. The present volume treats in detail of the wings, fuselage, tail plane and elevators, landing gear and rear skid, control surfaces, flying controls and details, and is equipped with numerous tables of data needed by the designer. Complicated mathematical discussions are avoided.

Automotive Ignition Systems. By Earl I. Consoliver and Grover I. Mitchell. First edition. McGraw-Hill Book Company, Inc., New York, 1920. (Engineering education series.) Cloth, 6 × 9 in., 279 pp., illus., diagrams, $2.50.

This is a systematic course of study of the ignition systems used on automobiles, tractors and airplanes, for those who have to install, adjust and repair these systems in the factory and repair shop.

Concrete Work. By William Kendrick Hatt and Walter C. Voss. Vol. 1, N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1921. 451 pp., illus., diagrams, tables, 8 × 6 in., cloth, $4.00.

This is the first part of a two-volume manual intended to extend the scope of work now possible to the concrete worker of unguided experience by bringing him to an intelligent understanding of the scientific principles underlying his art, and by introducing him to the wider opportunities that exist for him in modern construction. The method used to present the subject is based upon the experience acquired by the Committee on Education and Special Training of the War Department, in training 130,000 soldiers in the various trades connected with military operations. The present volume of the manual contains the development of principles and information on methods of construction and standards necessary for the construction of the definite building.

Contracts in Engineering. By James Irwin Tucker. Second edition, seventh thousand. McGraw-Hill Book Co., New York, 1920. Cloth, 6 × 9 in., 331 pp., $4.

This book is intended as a practical course showing the contractual basis of engineering work and of business at large, and as a textbook for engineering students with no opportunity for extended study of legal principles. It aims to present those facts and rules that seem likely to be of most value to an engineer in his professional and business career and to give him substantial information upon many legal matters.

Drang und Zwang; Eine Höhere Festigkeitslehre fur Ingenieure. Von Aug. Föppl und Ludwig Föppl. R. Oldenbourg, München und Berlin, 1920. Paper. 2 vols. 7 × 70 in., 72 Marks.

The authors of these volumes discuss some of the more abstruse problems of stress and strain. The work is intended especially for engineers who are fitted, by practical experience, to follow a difficult investigation and apply its results. A knowledge of the elementary theory of the mechanics of materials is expected of the reader.

Exporter's Gazetteer of Foreign Markets, 1920–21. Compiled and edited by Lloyd R. Morris. The American Exporter, New York. Cloth, 6 × 9 in., 789 pp., maps, tables, $10.

This gazetteer is planned to present concisely facts about markets which have heretofore been obtainable only in scattered primary sources. The information includes the area and population of each country, the population of its principal towns, its commerce, production and industry, telegraphs, telephones and railroads, money, weights and measures, commercial language, principal shipping routes, customs tariff, consular regulations and representation, and similar matters. Maps of the principal countries are included. Foreign currencies and measurements have been converted into American equivalents.

This book is for officers of manufacturing corporations, works managers, superintendents, accountants, and those in charge of such activities as purchasing, stores, costs and production. The present edition has been revised to conform with the evolution of practice and standards, particularly in relation to organization, personnel problems and the functional control of production. An extensive bibliography is included.

The Gasoline Automobile; its Design and Construction. Vol. 1, The Gasoline Motor. By P. M. Heldt. Sixth edition. P. M. Heldt, Nyack, N. Y., 1920. Cloth, 6 × 9 in., 639 pp., illus., diagrams, charts, $6.

Continued development of the internal-combustion engine has made necessary a further revision of this volume. The chapters on the cylinder, crankcase and oiling system have been rewritten, and that on the piston, piston rings and piston pin revised to accord with modern practice. New material on other subjects has been added in an appendix and a number of new plates have been included.

Heat Engines; a Text-Book for Engineering Students. By David Allen Low. Longmans, Green and Co., New York, 1920. Cloth, 6 × 9 in., 597 pp., illus., diagrams, charts, tables, $6.50.

The author has attempted to compress into one volume of moderate dimensions sufficient material for a two-years' course in the subject, in which its theoretical and practical sides would be combined, Numerous exercises for the student are included, most of which are original.

The Making of Herbert Hoover. By Rose Wilder Lane. The Century Co., New York, 1920. Cloth, 5 × 8 in., 362 pp., portraits, $2.50.

Upon the foundation of documents, letters and diaries, and information supplied by Charles K. Field, a friend and college classmate of Mr. Hoover, Mrs. Lane has prepared an informal, readable account of his life. The book is unusual in method, but achieves success as an interpretation of the man.

Tanks in the Great War, 1914–1918. By J. F. C. Fuller. E. P. Dutton and Company, New York, 1920. Cloth, 6 × 9 in., 345 pp., frontispiece, maps, plates, $9.

This volume, by a former Chief General Staff Officer of the Tank Corps of the British Army, is a readable account of the genesis of the tank and of the part played by it in the Great War. The work of the French, German and American tank corps is covered also.

Address on Industrial Waste by Herbert Hoover

(Continued from page 217)

priate character to our needs. Today we have capacity for production of some commodities not only in excess of our home need, but even beyond export demand under present financial conditions. As a matter of practical remedy, we must either reorganize these financial relations or alternately abandon some part of this kind of production and turn our idle men to making things of which we are not yet fully supplied.

The largest area of waste lies in the large periods of slack production and unemployment, due to the ebb and flow of economic tides between booms and slumps. The ideal would be steadily increasing production—an ideal of no likelihood of exact realization because of inability to ever gage in advance the growth in consumption or the approach of saturation. On the other hand, there are certain possibilities of stabilization worth consideration. Our studies of industries as a whole show that we usually expand our equipment just at the periods of maximum demand for their products instead of doing our plant expansion during periods of slack consumption. We thus make double demands on labor and we doubly increase unemployment in periods of reduced consumption. That is indeed one of the factors in our great unemployment today.

Everyone knows that for our normal productivity, our transportation facilities are today inadequate. We know that we are insufficiently housed, insufficiently equipped in our public roads and our public utilities; that we need an entire revision of our power supply, that we need expansion of our water ways; and yet armies of idle men are walking the streets.

The reasons why this occurs are not far to seek, in that it is at times of high productivity that capital is most easily obtained. It is then that the necessity of increased equipment most impresses men's minds and it is the high hopes of these periods that lead them into the adventure of expansion. Nor is it possible to expect that all industry can be so stabilized as to do its capital construction in periods of depression in commodity

demand. Nevertheless, there are some industries that could, by coöperation of the Government and coöperation among themselves, be led in this direction. More particularly does this apply to railways, telephones, telegraphs, power supplies and other public utilities, and to the expenditure upon our state, municipal and national public works.

Another variety of intermittent employment, and thus great waste, lies in certain industries now operating upon an unnecessarily wide seasonal fluctuation, as for instance the bituminous-coal industry. This is today one of our worst-functioning industries. These mines operate seasonally and erratically. They proceed from gluts to famines, from profiteering to bankruptcy. The mining engineers have already pointed out the direction in which the remedy lies, through storage, through railway rate differentials and other remedies. Through constructive action, an army of men could be released from this industry to convert some luxury into a necessity of tomorrow.

The second largest area of waste in productivity is the eternal amount of labor friction, strikes and lockouts. Fundamentally this is not alone a struggle for division of the results of production between capital and labor, but also in the element of purely human friction and loss outside the area of dispute on wages and hours. The growth of industry into large units has destroyed the old mutuality of interest between employee and employer. Our repetitive processes have tended to destroy the creative instinct and interest in employees; at times their efforts sink to low levels indeed. We will yet have to reorganize the whole employment relationship to find its solution. There is great promise in this field during the past two years, and the progress in this matter is one of the subjects under our inquiry.

Probably the next largest fraction of waste in productivity lies in a too high degree of individualism in certain basic products and tools. In other words, a standardization of certain national utensils makes for economy in distribution, in operation and in repairs. The necessity of maximum production during the war opened a great vista of possibilities in this direction. Such standardization as car couplings, or wheels, and cars generally, represents real progress in this direction. These possibilities lie in a hundred directions. There are all sorts of cases from sizes of chains to the size of automobile wheels. Today dozens of different sizes are placed in the market by manufacturers and entail not only special equipment and skill to produce these many varieties, but also great stocks are required in distribution and losses are entailed due to lack of interchangeability. Standardization does not mean that we stamp the individuality out of manufacture or invention or decoration; it means basic sizes to common and everyday things.

Another type of waste lies in our failure to advance our industrial equipment. The Super-Power Board will demonstrate the saving of 25,000,000 to 50,000,000 tons of coal annually by the electrification of our eastern power supply. The St. Lawrence Waterway Commission will demonstrate the saving of five to ten cents a bushel to the farmers of fifteen states by unlocking the lakes to ocean-going vessels.

Plans for Organizing Port of New York

(*Continued from page 211*)

railroads giving pier-station service; a joint yard and transfer station on this belt line; two parallel but independent tracks of standard gage in a loop in separate tunnels from the yard to Manhattan and back to the yard; a series of multiple-story terminals in Manhattan with car elevators to the surface from underground sidings; a fleet of special electrically operated cars and a fleet of special four-wheel trailer trucks. The tunnels will be far enough below surface so that rapid passenger transite development will not be hindered.

At the joint transfer station in New Jersey (see map) inbound freight will be transferred to trailer trucks, which will be borne by the electrically operated cars, mainly in a eight-car trains, to the Manhattan stations. The trains will be run at uniform rates of speed not exceeding 14 miles per hour, making it safe to move the trains at short intervals. At the stations the cars will be raised to the surface one at a time and their loads exchanged for trailers bearing outbound freight, after which they will be despatched in eight-car trains to the transfer station and unloaded into standard freight cars. The electric cars will move around the loop on either track in one direction only, each loop thus forming an independent line.

Figures prepared by the Commission show terminal costs of \$1.82 per ton with this scheme as compared to \$2.25 per ton with the present car float-pier station system and compared with \$3.50 for standard-equipment elevated or underground systems.

The automatic-electric system is a radical device for port development, although it has been tried on a smaller scale by the London Post Office. The proposed scheme with its deep-laid tunnels has the advantage of being cheap to operate, is not affected by weather conditions, and removes trucking congestion in the already overcrowded streets of Manhattan.

CLOTHS FOR MECHANICAL USES

(*Continued from page 180*)

2 Machine leaders for:

Back filling	Drying	Shearing
Brushing	Felt hardening	Singeing
Calendering	Ironing	Sprinkling
Crabbing	Pressing	Starching
Dewing	Sanding	Water mangling

e Jackets. (Woolen):
Fulling-mill rolls
Gig rolls.

f Jute Cloth:

Aprons on take-up rolls	Leader on felt hardeners
Aprons on loom beams	

g Laminated Cloth. (Cotton):

Check straps	Lug straps
Gears	Pickers
Harness straps	

h Printing. (Cotton, linen and wool):
See general head Printing

i Sheets. (Cotton or wool):

Extractor linings	Fulling-mill linings

j Steaming Blankets:
Wool

k Tapes and Webbing. (Cotton and asbestos):

Apperly feed bands	Harness straps	Slubbers
Can drier leaders	Mules	Spinning frames
Condensers	Machine belts	Spoolers
Doublers	Reducers	Twisters
Finishers	Roving frames	Winders

Asbestos. Asbestos cloth is such an unusual product, so unlike any other cloth that it is advisable to take it up separately. The two main fundamental differences in its use are, first, its heat- and flame-resisting qualities; and second, its neutrality to the actions of acids and alkalis. For these two reasons it can be used in places where no other fabric can. The cloth is usually of heavy yarns and a plain weave, varying in closeness of mesh and thickness as the purpose requires.

The great bulk of this cloth goes into steam packing. It is invaluable in this respect. In this is included gaskets and cut washers. The next largest amount goes into brake linings of all kinds, principally automobile. These may be entirely asbestos or wire warp with asbestos filling. Clutch facings come next in volume.

Filter cloths of various degrees of openness and thickness are used, mostly in chemical plants. Wire backings may be used in this work. This type of filter cloth is also used in making such gases as oxygen and hydrogen, and in such plants where refuse or sewerage has to be disposed of. The cloth is easily cleaned by subjecting to fire.

In the electrical industry asbestos cloth is used mostly in webbing or tape form in the manufacture of armatures, etc., and greatly in wire and cable manufacture. Tubing of this material is used also in cable manufacture and gives excellent protection.

For fire doors, heat screens, and curtains a heavy fabric is used, either plain or with a wire warp. Theater curtains are of this type. Iron and steel mills use this cloth around furnaces, etc. Light asbestos cloth is used to wrap asbestos or magnesia packing, but in general heavy cotton sheeting or light duck is best for this purpose.

The making of asbestos board, wall board, linings, shingles, etc., is practically dependent on a textile product, an endless woolen blanket a form of papermakers' felt. The sheet of asbestos is formed on this woolen blanket or felt, the stock being carried through press rolls and finally delivered in a formed but moist sheet to driers. This blanket is made of heavy woolen yarns about one-quarter to one-eighth run, twisted two, three or four strands together. It is a plain weave cloth, about six warps threads and six picks fulled heavily and lightly napped on one side to enable a new felt to easily start the stock. As to the exact workings of this endless woolen blanket or felt, see the paragraphs on Paper Industry, the principle being the same.

It will be found that in what has gone before there are a number of repetitions due to the unavoidable use of conflicting headings. The author by no means considers that every mechanical use is covered by the paper, but he does feel that it gives an idea of the tremendous use of cloth for mechanical uses and its importance in machine design, construction and operation.

THE ENGINEERING INDEX

(Reg. U. S. Pat. Off.)

THE ENGINEERING INDEX presents each month, in conveniently classified form, items descriptive of the articles appearing in the current issues of the world's engineering and scientific press of particular interest to mechanical engineers. At the end of the year the monthly installments are combined along with item dealing with civil, electrical, mining and other branches of engineering, and published in book form, this annual volume having regularly appeared since 1906. In the preparation of the Index by the engineering staff of The American Society of Mechanical Engineers some 1200 technical publications received by the Engineering Societies Library (New York) are regularly reviewed, thus bringing the great resources of that library to the entire engineering profession.

Photostatic copies (white printing on a black background) of any of the articles listed in the Index may be obtained at a price of 25 cents per page, plus postage. A separate print is required for each page of the larger periodicals, but wherever possible two small or medium-sized pages will be photographed together on the same print. The bill will be mailed with the print. When ordering photostats identify the article by quoting from the Index item: (1) Title of article; (2) Name of periodical in which it appeared; (3) Volume, number, and date of publication of periodical; (4) Page numbers. Orders should be sent to the Engineering Societies Library, 29 West 39th Street, New York.

ABRASIVE WHEELS

100,000 r.p.m. Grinding-Wheel Spindle Operated at an Unusual Speed. Machy. (N. Y.), vol. 27, no. 5, Jan. 1921, p. 420, 2 figs. Spindle manufactured by A. A. Jones & Shipman Co., Ltd., Leicester, England, and designed to be operated at speed of 104,000 r.p.m. Drive is through intermediate shaft and special rubber belts are used. Spindle, which is in experimental stage, was shown at machine-tool exhibition recently held in London.

ACCIDENT PREVENTION

Foundry. Safe Shoes Reduce Hot-Metal Burns. Foundry, vol. 49, no. 2, Jan. 15, 1921, pp. 51–53, 5 figs. One-sixth of total foundry accidents are ascribed to defective and unsafe foot-wear. Foot injuries are reduced by proper shoes.

ACCIDENTS

Dust Explosions. A Dust Explosion During the Handling of Cottonseed Meal, David J. Price. Am. Fertilizer, vol. 54, No. 1, Jan. 1, 1921, pp. 53–57, 5 figs. Account of dust explosion which occurred during handling and elevating of cottonseed meal.

Causes and Prevention of Dust Explosions. Colliery Guardian, vol. 120, no. 3128, Dec. 10, 1920, pp. 1677–1678, 1 fig. Account of German experiments. Translated from Zeitschrift für Berg-, Hütten- und Salinenwesen.

Engineering Problems in Dust Explosion Prevention, David J. Price. Chem. & Metallurgical Eng., vol. 24, No. 1, Jan. 5, 1921, pp. 29–32, 5 figs. Notes on causes and factors effecting dust explosions. Types of industrial plants affected. Ignition temperatures, propagation and velocity of flame, pressures developed and relation of humidity and prevention of explosions.

The Prevention of Dust Explosions, Hylton R. Brown. Am. Industries, vol. 21, no. 6, Jan. 1921, pp. 27–29, 2 figs. Tests at Bureau of Chemistry, U. S. Dept. of Agriculture.

Eye Injuries. Factory Eye Room Saves Workers' Sight and Increases Output, Sanford DeHart. Indus. Management, vol. 61, no. 1, Jan. 1, 1921, pp. 23–24, 1 fig. Experience of R. K. LeBlond Machine Tool Co.

The Economic Aspect of Eye Injuries, T. Lister Llewellyn. Colliery Guardian, vol. 120, no. 3129, Dec. 17, 1920, p. 1749. Analysis of total accident claims made at a number of British coal and iron mines.

AERONAUTICAL INSTRUMENTS

Control Compass. A Remote Control Compass, Alfred Gradenwitz. Aviation, vol. 10, no. 1, Jan. 3, 1921, pp. 19–20, 7 figs. Bamberg remote control compass.

Route Indicator. Route Indicator (Le correcteur de route), M. Le Prieur. Aéronautique, vol. 2, no. 18, Nov.-Dec. 1920, pp. 227–232, 23 figs. Also Aérophile, vol. 28, no. 22–23, Nov. 1–15, 1920, pp. 326–332, 17 figs. Description of derivograph, an apparatus which indicates direction, corrected for wind, to follow in order to reach a certain place by flight in a straight line.

Turn Indiactor. Instruments for the Navigation of Aircraft, G. M. B. Dobson. Nature (Lond.), vol. 106, no. 2668, Dec. 16, 1920, pp. 504–506, 4 figs. Gyro turn indicator, gyro rudder control, pneumatic air log and bubble sextant.

AERONAUTICS

Flying Fish, Flight of. The Aeronautics of the Flying Fish, R. E. Dowd. Aerial Age, vol. 12, no. 18, Jan. 10, 1921, pp. 464–465, 4 figs. Study of forces acting. Mechanism of flight.

AEROPLANE ENGINES

Design. Some Possible Lines of Development in Aircraft Engines. H. R. Ricardo. Flight, vol. 12, no. 53, Dec. 30, 1920, pp. 1311–1316, 20 figs. Raising compression, proportioning mixture, and limiting size of cylinder. (Abstract.) Paper read before Royal Aeronautical Soc.

Engine Clearance Volumes. Instrument for Measuring Engine Clearance Volumes, S. W. Sparrow. Aerial Age, vol. 12, no. 16, Dec. 27, 1920, pp. 419–420, 6 figs. Apparatus designed and constructed under direction of Automotive Power Plants Section, Bureau of Standards.

Fuel. See GASOLINE, Hecter Fuel.

Hall-Scott. Building Motors on the Pacific Coast, Fred H. Colvin. Am. Mach., vol. 53, no. 27, Dec. 30, 1920, pp. 1215–1220, 29 figs., and vol. 54, no. 2, Jan. 13, 1921, pp. 46–47, 11 figs. Dec. 30: Machining of crankcases for both aircraft and marine types of motors. Jan. 13: Method of facing inside of aluminum-alloy piston.

Starting Torque. Starting Torque on Liberty, Hispano-Suiza, and Other Aviation Engines. Air Service Information Circular, vol. 2, no. 126, Nov. 6, 1920, 3 pp. Starting torque required for Liberty engine of 400-hp. rating and with 12 cylinders was 124 lb-ft. with throttle open and 143 with throttle closed; for Hispano-Suiza of 300 hp. with 8 cylinders, these figures were respectively 102 and 96.

AEROPLANE PROPELLERS

Design. The Metal Airscrew, M. A. S. Riach. Aeronautics, vol. 19, no. 375, Dec. 23, 1920, pp. 450 and 459, 2 figs. Metal versus wood for aeroplane propellers.

Gear Drive. Experience with Geared Propeller Drives for Aviation Engines, K. Kutzbach. Aerial Age, vol. 12, nos. 17 and 18, Jan. 3 and 10, 1921, pp. 442–445, 9 figs., and 466–469, 18 figs. Stresses in gear wheels; table of gears from captured engines; arrangements of gear. Translated from Technische Berichte.

AEROPLANES

Design. Aeroplane Design, F. S. Barnwell. Aeronautics, vol. 19, no. 376, Dec. 30, 1920, pp. 466–467, 1 fig. Present tendencies and future possibilities. (To be continued.)

Structural Analysis and Design of Aeroplanes, B. C. Boulton and A. S. Niles. Aerial Age, vol. 12, no 18, Jan. 10, 1921, pp. 469–470. Review of book by B. C. Boulton in charge of stress analysis and structural design, McCook Field.

Farman. Recent Farman Types of Aeroplanes (Die neueren Farman-Flugzeuge), Luftfahrt, vol. 24, no. 10, Oct. 7, 1920, pp. 145–147, 3 figs. Details of various Farman types which are then compared to corresponding German types, including the Dornier, Junkers, Sablatnig and Fokker, showing, in writer's opinion, the greater advance made in aeroplane construction in Germany during last six years.

Gastambide-Levavasseur. Aeroplanes in Which the Three Elements, Surface, Curvature and Incidents are Variable (L'avion a surface, courbure et incidence variables), Georges Blanchet. Aérophile, vol. 28, no. 22–23, Nov. 1–15, 1920, pp. 321–325, 4 figs. Description of Gastambide-Levavasseur machine.

Helicopters. See HELICOPTERS.

Large, Possibilities of. The Possibilities of the Large Airplane, F. H. Norton. Aviation, vol. 10, no. 2, Jan. 10, 1921, pp. 48–50, 10 figs. Structural and aerodynamic problems of large aeroplane.

Longitudinal Stability. Statical Longitudinal Stability of Airplanes, Edward P. Warner. Nat. Advisory Committee for Aeronautics, report no. 96, 1920, 28 pp., 14 figs. Results of experimental work, together with details of theoretical analysis of statical stability, of factors which affect it, and of methods which can be employed for its modification.

Model Tests. Value of Model Tests, J. W. Margoulis. Aviation, vol. 10, no. 2, Jan. 10, 1921, pp. 40–42, 1 fig. Influence of ratio of dimensions of model and speed of test to dimensions of full scale machine and its speed of flight.

Single-vs.-Twin-Engined. A Comparison of the Flying Qualities of Single and Twin-Engined Aeroplanes. Aeronautical Jl., vol. 24, no. 120, Dec. 1920, pp. 616–627. Factors in design which are most vital to pilot and how they influence his handling of aeroplane.

Stability. Diagrams of Airplane Stability. H. Bateman. Nat. Advisory Committee for Aeronautics, report no. 95, 1920, 25 pp., 28 figs. Effect on period and rate of subsidence of pitching oscillations of an airplane of a change in one of resistance derivatives when all others are kept constant.

Wind Tunnels. See WIND TUNNELS.

Wings. Slotted Airplane Wings. Sci. Am. Monthly, vol. 3, no. 1, Jan. 1921, pp. 66–67, 2 figs. Handley Page wings of Venetian blind form.

The Handley-Page Wing (L'aile Handley-Page) E.-H. Lemonon. Aérophile, vol. 28, no. 22–23, Nov. 1–15, 1920, pp. 333–334, 9 figs. Wing is made up of separate elements which separate or come together like Venetian blind.

AIR

Dust-Content Determination. Efficiency of the Palmer Apparatus for Determining Dust in Air, S. H. Katz, E. S. Longfellow and A. C. Fieldner. Jl. Am. Soc. Heat. and Vent. Engrs., vol. 26, no. 8, Nov. 1920, pp. 687–700, 5 figs. Two methods of testing were used. In first efficiency was determined on basis of surface of particles entering apparatus as compared with surface leaving, by use of Tyndall effect. Second method was based on weight of dust, and used small laboratory Cottrell precipitator in series with Palmer washer.

AIR COMPRESSORS

Centrifugal. The General Behavior of the Centrifugal Compressor (Das allgemeine Verhalten der

Kreiselverdichter), Gustav Flügel. Zeit. des Vereines deutscher Ingenieure, vol. 64, no. 49, Dec. 4, 1920, pp. 1027–1032, 4 figs. Under presumption of unchangeable air temperature the compression phenomenon with the multi-stage centrifugal compressor for any working conditions is investigated, first according to a very accurate method and then according to a simple approximate method. It is shown that the equations derived define the variable air temperature with the same accuracy, providing the mean temperature is calculated.

Heat Utilization. The Economic Utilization of the Compression Heat in Large Compressors (Die wirtschaftliche Ausnutzung der Kompressionswärme in grösseren Verdichtern), Erich Lampel. Fördertechnik u. Frachtverkehr, vol. 13, no. 21, Oct. 15, 1920, pp. 193–195, 2 figs. Heat resulting from compression said to be a drawback. Utilization of latent heat according to method heretofore used of introducing cooling water is claimed to be impossible, and a new arrangement is described for admission of cooling water and intermediate cooling, resulting in considerable reduction of volume of water and increase in temperature drop. Its useful possibilities are set forth.

High-Pressure. High-Pressure Air and Gas Compressors. Eng., vol. 110, no. 2869, Dec. 24, 1920, pp. 829–831, 3 figs. Six-Stage 4500-lb. per sq. in. compressor built to order of British admiralty for naval experimental station described in second installment.

Steam-Driven High-Pressure Four-Stage Gas Compressor. Eng., vol. 110, no. 2868, Dec. 17, 1920, pp. 800–802, 12 figs., partly on supp. plate. Two types, one compressing to 2250 lb. in four stages and other to 4500 lb. in six stages. Former type is described in first installment. (To be continued.)

Manufacture. Building Air Compressors. Eng. Production, vol. 2, no. 14, Jan. 6, 1921, pp. 7–12, 14 figs. Manufacturing methods in plant of Reavell & Co., Ipswich, England.

AIR CONDITIONING

Humidifier. Physiological Heat Regulation and the Problem of Humidity, E. P. Lyon. Jl. Am. Soc. Heat. and Vent. Engrs., vol. 26, no. 8, Nov. 1920, pp. 677–685. Importance of using humidifier in connection with heating system in houses and factories.

AIR SERVICE, UNITED STATES

United Force. United Air Force - Pro and Con. Aviation, vol. 9, no. 15, Dec. 27, 1920, pp. 480–482. Survey of reasons which reflect position of many Naval officers for united service and reasons of many Army officers who favor separate department.

AIRSHIPS

Mooring. Airship Mooring and Handling. F. L. C. Butcher. Aeronautics, vol. 19, no. 374, Dec. 16, 1920, pp. 432–435. Advantages and disadvantages of windscreens. Experiments with drogues. Paper read before Royal Aeronautical Soc.

Piloting. Airship Piloting. G. H. Scott. Flight, vol. 12, no. 50, Dec. 9, 1920, pp. 1254 1258. Difficulties encountered in airship piloting and methods employed to overcome these difficulties. Paper read before Royal Aeronautical Society.

Rigid. Operation of a Rigid Airship, L. H. Maxfield. Aviation, vol. 10, no. 1, Jan. 3, 1921, pp. 15–16. Duties of airship crew.

ALCOHOL

See AUTOMOBILE FUELS, Alcohol.

ALUMINUM

Castings. Analyze Loss in Aluminum Shops—II, Robert J. Anderson. Foundry, vol. 49, no. 1, Jan. 1, 1921, pp. 16–21. Effect on casting losses of stock used in melting charge and also of pouring temperature and melting practice, including type of furnace used.

Density. Density of Aluminum from 20 to 1000 Deg. Cent., Junius David Edwards and T. A. Moormann. Chem. & Metallurgical Eng., vol. 24, no. 2, Jan. 12, 1921, pp. 61–64, 3 figs. Experimental methods for measuring with precision density of liquid metals, and figures for results when applied to pure aluminum. Derived data of importance are solid shrinkage, or pattern allowance, and solidification shrinkage.

Soldering of. The Practicability of Soldering Aluminum, A. N. Fleming. Sheet Metal Worker, vol. 11, no. 15, Dec. 24, 1920, pp. 427 and 433, 1 fig. How aluminum transmission case was repaired by soldering.

ALUMINUM ALLOYS

Magnesium. The Constitution of the Alloys of Aluminium and Magnesium, D. Hanson and Marie L. V. Gayler. Eng., vol. 110, nos. 2867–2868, Dec. 10–17, 1920, pp. 788–791 and 17 figs., 819–821, 18 figs. Research carried out in Metallurgy Department of National Physical Laboratory, England. Determination of solidus. Photomicrographs. Abstract of paper read before Inst. Metals.

AMMONIA

Properties. Properties of Ammonia. Refrigerating World, vol. 55, no. 12, Dec 1920, pp. 21–28. Tables prepared by National Bureau of Standards with coöperation of American Society of Refrigerating Engineers.

AMMONIA COMPRESSORS

Development. The development of the Modern High Efficiency Ammonia Compressor Through the Application of the Worthington Feather Valve, Thos. D. McKee. Ice & Refrigeration, vol. 60, no. 1, Jan. 1921, pp. 13–15. Advantages of high speed ammonia compressors.

APPRENTICES, TRAINING OF

Machinists. Training Operators in a Machine Shop, John C. Spence. Machy. (N. Y.), vol. 27, no. 5, Jan. 1921, pp. 421–423, 2 figs. Methods employed in plant of Norton Co., Worcester, Mass., in training of machine-shop workers.

Work of the German Committee for Technical Instruction in the Training of Apprentices in the Metal Industry (Die Arbeiten des Deutschen Ausschusses für Technisches Schulwesen auf dem Gebiete der Lehrlingsausbildung in der Metallindustrie), A. Heilandt. Betrieb, vol. 3, no. 5, Dec. 10, 1920, pp. 13–20, 15 figs. Work already completed: Course for training of apprentices for machine construction; curriculum for schoolroom instruction of apprentices for machine construction; workshop textbook.

Training the Machinist of the Future, J. H. Moore. Can. Machy., vol. 25, no. 2, Jan. 13, 1921, pp. 33–38, 12 figs. Organization and operation of Hamilton Technical & Art School.

Railroad Shop. A Railroad Shop's Apprentice School, J. V. Hunter. Am. Mach., vol. 54, no. 3, Jan. 20, 1921, pp. 97–98, 1 fig. Training school in Decatur locomotive and car shops of Wabash Railway Co. Current expenses defrayed by assessing apprentices. Regular and helper courses given.

Systems. Programs of Apprenticeship and Special Training in Representative Corporations—VIII, J. V. L. Morris. Am. Mach., vol. 54, no. 1, Jan. 6, 1921, pp. 13–14, 4 figs. System at plant of United Shoe Machinery Co., Beverly, Mass. Boys attend school and shop on alternate weeks and school work is given in coöperation with public-school system.

ASH HANDLING

Pneumatic Plants. Pneumatic Ash-Removal Installations in Heating Plants (Pneumatische Entaschungsanlagen in Heizwerken), W. Uhlig. Elektrotechnische Rundschau, vol. 37, nos. 16 and 17, Aug. 21 and Sept. 7, 1920, pp. 73–75 and 79–81, 6 figs. It is claimed that in spite of fact that power consumption of installations with impeller exhausters is generally high as compared to those with piston pumps, they have great advantages including lack of sensitivity to smoke and hot gases.

AUTOGENOUS WELDING

Cylinder Repair Work. Cylinder Repair Work, Wabash Shops, Decatur, Illinois, J. G. Cunningham. Autogenous Welding, Jan. 1921, pp. 36–38, 8 figs. Examples of repairs made at Wabash Railroad shops.

AUTOMOBILE ENGINES

Carburetors. See CARBURETORS.

Connecting Rods. Making Connecting-Rods for Franklin Cars, Franklin D. Jones. Machy. (N. Y.), vol. 27, no. 5, Jan. 1921, pp. 470–474, 11 figs. Machines and fixtures used at plant of H. H. Franklin Mfg. Co., Syracuse, N. Y., for drilling, boring, milling, grinding, reaming and gaging operations.

Cylinders. See CYLINDERS, Manufacture.

Design. Possible Fuel Savings in Automotive Engines, H. C. Dickinson and S. W. Sparrow. Jl. Soc. Automotive Engrs., vol. 8, no. 1, Jan. 1921, pp. 3–9, 14 figs. Notes on design of manifold and chemical operation of automotive engines. Paper read before Am. Petroleum Inst.

Gasoline Losses. Gasoline Losses Due to Incomplete Combustion in Motor Vehicles, A. C. Fieldner. A. A. Straub and G. W. Jones. Jl. Indus. & Eng. Chem., vol 13, no. 1. Jan. 1921, pp. 51–58, 7 figs. Results of tests under spring and summer conditions.

Horsepower Formulas. A Compilation of the Horsepower Formulas for Different Countries (Zusammenstellung der Steuerformeln für verschiedene Länder), Richard Bussien. Motorwagen, vol. 23, no. 28, Oct. 10, 1920, p. 527. Gives German, Belgian, French, English, Swedish. Italian, Japanese, Spanish, Hungarian and Californian formulas.

New York Show. Engines Exhibited at New York Show, P. M. Heldt. Automotive Industries, vol. 44, no. 2, Jan. 13, 1921, pp. 53–58, 15 figs. Survey of exhibits.

Suspension. A New Principle of Engine Suspension, S. E. Slocum. Jl. Soc. Automotive Engrs., vol. 8, no. 1, Jan. 1921, pp. 54–56, 1 fig. Suspension on three points so as to destroy synchronism between oscillating machine and support so far as transmission of vibrations is concerned.

AUTOMOBILE FUELS

Alcohol. Significance of Alcohol in the Motor Fuel Problem, Burnell R. Tunison. Automotive Industries, vol. 44, no. 1, Jan. 6, 1921, pp. 14–17, 5 figs. Advantages of and need for using synthetic fuel containing alcohol. Data regarding performance of engines using alcohol.

Benzol. The Manufacture of Motor Spirit in Gasworks. Gas World, vol. 73, no. 1900, Dec. 18, 1920, pp. 493–494. Stripping process of benzol recovery and its financial results.

Gasoline. See GASOLINE.

Palm Oil. Belgian Experiments on Palm Oil as Motor Fuel. Commerce Reports, no. 1, Jan. 3, 1921, pp. 10–11. Series of experiments begun 1914, but interrupted by war, has recently been resumed in Brussels on use of palm oil in internal-combustion motors. Tests have so far proven satisfactory.

AUTOMOBILES

Body Design. American and British Bodywork at Olympia Compared, M. W. Bourdon. Automotive Industries, vol. 43, no. 26, Dec. 23, 1920, pp. 1256–1261, 12 figs. American bodies said to lack finish and comfort as compared to British product selling in England at same price. British cars generally have lower seats but thicker cushions tilted toward rear and greater freeboard.

Body Suspension. Study of Suspension on Automobile Bodies and of Shock Absorbers (Étude sur la suspension des véhicules et les amortisseurs), G. Puica. Vie Technique & Industrielle, vol. 2, no. 14, Nov. 1920, pp. 117–120, 4 figs. Formula for designing springs. Study of stresses in spring plates.

The Mutti Suspension. Autocar, vol. 46, no. 1315, Jan. 1, 1921, p. 8, 2 figs. Design employing variable-tension coil spring. It has been tested with trailer and is suggested as substitute for ordinary car suspension.

Brakes on Four Wheels. Another French Car Using Brakes on Four Wheels, W. F. Bradley. Automotive Industries, vol. 43, no. 26, Dec. 23, 1920, pp. 1266–1268, 7 figs. Darracq now getting into production on eight-cylinder car, which has been modified since exhibit at Paris Salon a year ago. Engine has removable heads and uses battery ignition. Four-speed transmission and spiral-bevel final drive employed. Right-hand drive retained.

Design. European Automobile Design for 1921. Sci. Am., vol. 124, no. 1, Jan. 1, 1921, pp. 9 and 19–20. Comparison of European and American Practices.

Friction Drive. Friction Drive Revived in New Kelsey Six-Cylinder Car. Automotive Industries, vol. 43, no. 25, Dec. 16, 1920, pp. 1204–1206, 3 figs. Friction disk and wheel are located within rear axle housing, which is of aluminum alloy and is said to be lighter than standard type. Jackshaft carries helical pinion meshing with internal gear on wheel hub, giving 4.5 to 1 reduction. Wheelbase is 116 in. Engine $3^1/_8$ x $4^1/_4$ in. Falls.

Headlights. Report of the Committee on Automobile Headlighting Specifications. Trans. Illuminating Eng. Soc., vol. 15, no. 9, Dec. 30, 1920, pp. 848–866. Recommended practice in headlamp illumination.

Manufacture. More Power for Automobile Building. Power Plant Eng., vol. 25, no. 2, Jan. 15, 1921, pp. 101–110, 17 figs. New plant of Cadillac Motor Car Co., Detroit, Mich.

Metal Construction. Substitute Metals in Automobile Construction. Benno R. Dierfeld. Automotive Industries, vol. 43, no. 27, Dec. 30, 1920, p. 1309. How copper and aluminum were substituted for iron and steel in Germany during war.

Rear-Axle Housings. Machining Columbia Rear-Axle Housings. Fred H. Colvin. Am. Mach., vol. 54, no. 1, Jan. 6, 1921, pp. 27–30, 15 figs. Operations on drilling, boring, reaming, tapping machines. Press work assembling and testing.

Sheet Metal Work. Sheet Metal Work for Automobiles, Fred H. Colvin. Am. Mach., vol. 53, no. 26, Dec. 23, 1920, pp. 1165–1168, 16 figs. Machinery for stamping and cutting up strips into various lengths and also preparing material for presses.

Transmissions. Clutches, Transmissions and Universal Joints, Herbert Chase. Automotive Industries, vol. 44, no. 2, Jan. 13, 1921, pp. 79–81, 4 figs. Trend of design as revealed at New York Show.

Wheels, Steel-Disk. The Harvey Steel Disk Wheel. Automotive Industries, vol. 43, no. 25, Dec. 16, 1920, p. 1206, 2 figs. Design in which attempt has been made to reduce or eliminate rigidity characteristic of metal wheels.

AVIATION

Commercial. Commercial Aircraft, B. W. Townshend. Aeronautics, vol. 19, no. 373, Dec. 9, 1920, pp. 421–423, 1 fig. Position of airships and aeroplanes in future of aerial transport. Paper read before City and Guilds Engineering Society.

Commercial Aviation in Great Britain (La navigation commerciale aérienne en Grande-Bretagne) T. Génie Civil, vol. 77, no. 23, Dec. 4, 1920, pp. 456–460, 1 fig. Models submitted for air ministry competition held in September 1920. (To be continued.)

Developments. Recent Advances in Aviation, Thurman H. Bane. Jl. Soc. Automotive Engrs., vol. 8, no. 1, Jan. 1921, pp. 18–25, 26 figs. Aeroplanes and aeroplane engines developed during war.

Nationality Marks. International Aircraft Marking, Ladislas d'Orey. Aviation, vol. 9, no. 15, Dec. 27, 1920, pp. 484–486, 3 figs. Nationality and registration marks for aircraft. Proposed table of nationality marks.

Night Flying. Night Flying. Aeronautical Jl., vol. 24, no. 120, Dec. 1920, pp. 627–642 and (discussion) pp. 643–649. Experience during war. Best type of machine for night flying.

[See also FLIGHT.]

AVIATORS

Fatigue of. The Human Machine in Relation to Flying. Aeronautical Jl., vol. 24, no. 120, Dec. 1920, pp. 650–658 and (discussion) pp. 658–663. Reasons why pilots should have periodic intervals of rest. International convention fixed period of six months for civilian pilot.

Tests of. Observation, Selection, and Assignment. Air Service Information Circular, vol. 2, no, 120, Oct. 30, 1920, 8 pp. Qualities needed by aviators. Process of selecting from application.

Eng., vol. 110, no. 2866, Dec. 3, 1920, pp. 737–738, 2 figs. Machine devised by N. W. Akimoff for testing both static and dynamic balance of high-speed rotors.

BALLOONS

Sunlight, Effect of. Solar Radiation and Balloons, Junius David Edwards and Maurice Blaine Long. Aviation, vol. 9, no. 15, Dec. 27, 1920, pp. 487–490, 4 figs. Investigations at Bureau of Standards of effect of sunlight upon life and operating characteristics of lighter-than-air craft.

BEAMS

Vibrations from Shafting. See SHAFTS, Whirling Speeds.

BEARINGS

Manufacture. Modern Bearings (Les paliers modernes). Nature (Paris), no. 2428, Oct. 16, 1920, pp. 243–246, 2 figs. Developments in manufacture, with reference to type developed by Brown Boveri Co.

Self-Lubricating. Self-Lubricating Bearings. Iron Age, vol. 107, no. 2, Jan. 13, 1921, p. 146. Reliance type consisting of inner and outer casings joined by force fit. Tapered holes in inner casing are filled with lubricating mixture under pressure.

Testing. Testing Hardness of Bearings and Journal. Iron Age, vol. 106, no. 27, Dec. 30, 1920, pp. 1727–1730, 16 figs. Progress report of subcommittee on bearing metals of The American Society of Mechanical Engineers. Description of tentative scale of so-called microhardness that expresses in definite units relation of hardness between different materials.

BELTING

Balata. The Manufacture of Balata Belting. India Rubber World, vol. 63, no. 4, Jan. 1, 1921, pp. 236–238, 16 figs. Translated from Le Caoutchouc et la Gutta Percha.

Leather. A New Type of Leather Belt. Eng., vol. 130, no. 3389, Dec. 10, 1920, pp. 590, 2 figs. Patented by French inventor. Belt consists of backing 3 in. by 1/4 in. oak-tanned leather to underside of which are riveted three stips of chrome leather, each strip being about 3/16 in. wide by 3/32 in. thick. Attachment of strips to backing is effected by means of brass rivets pitched at 2 in. intervals.

Effect of Relative Humidity on Leather Belting, F. W. Roys. Belting, vol. 18, no. 1, Jan. 1921, pp. 40–48, 9 figs. Also Textile World Jl., vol. 59, no. 2, Jan. 8, 1921, pp. 93–97, 9 figs. Tests at Worcester Polytechnic Institute. With adjustments of regular oak belts at 55 per cent humidity, no change was found to either tighten or slacken belt so as to cause trouble.

BLAST-FURNACE GAS

Purification. Purification of Blast Furnace Gas (État actuel de l'épuration des gaz de hauts-fourneaux), M. Alexandre Gouvy. Revue de Métallurgie, vol. 17, no. 10, Oct. 1920, pp. 677–686, 7 figs. Dscription of Cottrell process using electricity at high tension.

BLAST FURNACES

Coke Efficiency. Blast Furnace Problems of To-day. C. E. Roberts. Eng. & Indus. Management, vol. 5, no. 1, Jan. 6, 1921, pp. 7–10. Coke efficiency, increase in moisture content, dust difficulty, scientific control of furnace working. Paper read before Staffordshire Iron & Steel Inst.

Operation, Chile. Green Wood in the Blast Furnace, François Prudhomme. Iron Age, vol. 107, no. 2, Jan. 13, 1921, pp. 121–122. Making pig iron of tofo ores at Corral, Chile. Wood charred in upper part of furnace and distillates recovered. Chilean Government report.

Reducing Reactions. Reducing Reactions in the Blast Furnace (Des réactions réductrices dans le haut fourneau), Em. Pierre. Revue universelle des mines, vol. 7, no. 5, Dec. 1, 1920, pp. 301–321, 5 figs. Researches showed that reaction by CO is best for reducing FeO. Studies of action of gas on minerals.

Slags. Sampling Blast Furnace Slags, W. M. Chegwidden. Iron Trade Rev., vol. 67, no. 26, Dec. 23, 1920, pp. 1750–1751. Relation of sulphur in slag to sulphur in pig iron.

BOILER FEEDWATER

Heating, Economic Advantages of. Exhaust Wastes. Power Plant Eng., vol. 25, no. 1, Jan. 1, 1921, pp. 72–74, 2 figs. Chart showing percentage of fuel saved by heating feedwater by exhaust steam.

BOILER FURNACES

See FURNACES, Boiler.

BOILER ROOMS

Design. Design of Large Boiler Plants, J. Grady Rollow. Jl. Am. Soc. Heat. and Vent. Engrs., vol. 26, no. 8, Nov. 1920, pp. 715–734, 10 figs. Typical double-wall boiler plant with furnace for burning coal and dry wood waste.

Economical Operation. Reducing Operating Costs in Boiler Rooms, John Rusen. Coal Industry, vol. 4, no. 1, Jan. 1921, pp. 14–18, 8 figs. Advises mechanical conveying for coal and ashes will materially reduce costs.

Remodeling. Remodeling Old Power Stations—Boiler-Plant Improvements, L. R. Lee. Power, vol. 106, no. 26, Dec. 23, 1920, p. 1670. 2 figs. Swedish device for removing soot and scale from stationary boiler tubes.

BOILERS

Cast-Iron vs. Wrought-Iron. Cast Iron versus Wrought Iron (Gusseisen oder Schmiedeeisen?), Otto Ginsberg. Gesundheits-Ingenieur, vol. 43, no. 41, Oct. 9, 1920, pp. 479–487. Contribution to the boiler problem in central heating plants. It is concluded that in case of careful manipulation of boiler, cast iron is superior to wrought iron for small and medium-size plants, but for very large plants the wrought-iron boiler is preferable.

Electrically Heated. Bergeon-Frédet Electrically Heated Steam Boiler (Le générateur de vapeur "Bergeon-Fredet" à chauffage électrique). Chaleur et Industrie, no. 7, Oct. 1920, pp. 403–405, 3 figs. Horizontal cylindrical type boiler heated by three-phase current of 50 periods under tension of 6300 volts.

Electrically Heated Boilers. Elec. Times, vol. 58, no. 1523, Dec. 23, 1920, p. 491, 2 figs. Boilers manufactured by Sulzer Bros., London.

Manhole Cutting. Ellipsograph for Manhole Cutting. Eng., vol. 110, no. 2868, Dec. 17, 1920, p. 817, 3 figs. Patented device.

Marine. See MARINE BOILERS.

Massachusetts Board Boiler Rules. Changes in Massachusetts Boiler Rules. Power Plant Eng., vol. 25, no. 2, Jan. 15, 1921, pp. 121–122. Changes adopted at public hearing held by Board of Boiler Rules.

Performance. Exact Data on the Performance of Steam Boiler Plants—IV, David Brownlie. Eng., vol. 110, nos. 2867–2868, Dec. 10–17, 1920, pp. 759–761 and 797–799. Average figures for performance of a number of different types of steam boiders.

Tubes. Influence of Expanding of Tubes on the Deformation of Tube Sheets of Locomotive Boilers (Influence du sertissage des tubes dans les déformations des plaques tubulaires de foyer des chaudieres locomotives), M. Haffner. Revue generale des Chemins de Fer, vol. 39, no. 4, Oct. 1920, pp. 133–138, 5 figs. Comparison of various methods of expanding.

BOILERS, WATER-TUBE

Connelly. Connelly Water-Tube Boilers. Can. Manufacturer, vol. 41, no. 1, Jan. 1921, pp. 76–77, 2 figs. Boilers of large capacity built for working pressure of 300 tons per sq. in.

BORING MACHINES

Horizontal. Rockford Heavy-Duty Horizontal Boring Machine. Am. Mach., vol. 53, no. 26, Dec. 23, 1920, pp. 1197–1198, 2 figs. Machine intended chiefly for work encountered in automotive field.

Taper-Turning Head. New Taper-Turning Head for Vertical Boring Mills. Engr., vol. 130, no. 3385, Nov. 12, 1920, p. 485, 5 figs. Attachment manufactured by George Richards & Co., Ltd., Broadheath, England.

BRAKES

Street-Car. A New Tramcar Brake. Engr., vol. 130, no. 3391, Dec. 24, 1920, pp. 642–643, 4 figs. Spencer-Dawson brake.

The Force Action of Brake Riggings, H. M. P. Murphy. Elec. Ry. Jl., vol. 57, no. 3, Jan. 15, 1921, pp. 116–119, 11 figs. Forms of levers used in brake rigging of electric cars. Study of forces acting at various points of levers.

BUSES

Trolley-Operated. Trackless Trolley in Two British Cities. Elec. Ry. Jl., vol. 57, no. 2, Jan. 8, 1921, pp. 77–79, 5 figs. Bradford, with three routes in operation, is planning three more. Buses are used as feeders for trolley system. Double-deck trackless-trolley bus has just been put in service. Keighley, after five years' experience, has added to its equipment, and now has nine buses in service.

C

CABLEWAYS

Design. Didactic Study of Aerial Cableways (Étude didactique des transporteurs aériens sur cables), Giulio Ceretti. Génie Civil, vol. 77, no. 22, Nov. 27, 1920, pp. 430–435, 12 figs. Details of design of cable junctions and suspension methods. (Concluded.)

CANALS

Electric Haulage of Barges. New Systems of Electric Haulage in Canals (Nouveaus systèmes de halage électrique sur les canaux), Édouard Imbeaux. Comptes rendus des Séances de l'Académie des Sciences. vol. 171, no. 21, Nov. 22, 1920, pp. 981–985. Recent developments in France.

CARBURATION

Theory of. Contribution to the Problem of Carburation (Contribution au "sujet" de la carburation), A. Grebel. Chaleur & Industrie, no. 8, Nov.-Dec. 1920, pp. 455–473, 15 figs. Technical study of principles upon which carburation is based and of their application to the carburation of gasoline engines and gas engines together with investigation of chemical pacticability of utilizing gas as fuel in automobile engines.

automobile carburetors, the Eureka, Graetzin, Lacharnay, Standard, Einhorn and Asmo carburetors.

Einhorn. The Einhorn Carburetor (Der Einhorn-Vergaser), Johannes Menzel. Allgemeine Automobil-Zeitung, vol. 21, no. 41, Oct. 9, 1920, pp. 26–28, 2 figs. Describes automatically adjustable carburetor for use of heavy fuels of all kinds, which won first prize at tests carried out by Gen. German Automobile Club in conjunction with Automotive Testing Commission.

Floatless. Floatless Carburetors Coming Into Use in Germany, Benno R. Dierfeld. Automotive Industries, vol. 43, no. 26, Dec. 23, 1920, pp. 1262–1265, 11 figs. Developments in carburetor design in Germany.

CARS

Ball Bearings for. Ball Bearings for Railway Cars. Ry. Mech. Engr., vol. 95, no. 1, Jan. 1921, pp. 23–24, 5 figs. Graphs of train resistance with journal bearings and with disk bearings.

Diesel-Electric Self-Propelled. Diesel-Electric Self-Propelled Railway Coaches. Engr., vol. 130. no. P3386, Nov. 19, 1920, p. 511. Swedish design, Translated from Génie Civil.

CASE-HARDENING

Furnace for. A New Method of Case-Hardening Steel, Wm. J. Merten. Am. Mach., vol. 53, no. 26, Dec. 23, 1920, pp. 1169–1170, 1 fig. Regenerative type of furnace.

CASTINGS

Die. Die Castings, W. Betterton. Metal Industry (London), vol. 17, no. 24, Dec. 10, 1920, pp. 461–464, 8 figs. Manufacture of castings are accurately cast to limit of one-thousandth of an inch so that no machining is necessary. Alloys from which such castings can be made are discussed and advantages of die casting are pointed out.

Inspection. Precise Inspection of Large and Irregular Curves, Elbert O. Brower. Am. Mach., vol. 54, no. 2, Jan. 13, 1921, pp. 60–66, 13 figs. Method for inspection of large and irregular curves, and its application to inspection of castings.

Iron. See IRON CASTINGS.

Malleable. Shop Specializes in Annealing Pots. Foundry, vol. 49, no. 1, Jan. 1, 1921, pp. 11–15, 7 figs. Manufacture of malleable castings on production basis.

Steel. See STEEL CASTINGS.

CEMENT

Natural. Australian Company to Work an Island of Cement Rock. Cement, Mill & Quarry, vol. 18, no. 1, Jan. 5, 1921, pp. 19–22, 5 figs. Concessions for operating deposits of natural cement located on Maria Island on east coast of Tasmania have been secured by National Portland Cement Co.

Setting Time. Modified Vicat Apparatus for Study of Setting Time of Cement, O. L. Moore. Eng. News-Rec., vol. 86, no. 2, Jan. 13, 1921, p. 70, 3 figs. Principle consists in balancing rod and needle by means of beam and weight and determining load necessary at time intervals to cause needle to penetrate definite distance into neat paste.

CEMENT, PORTLAND

Consolidation. Judging the Quality of Portland Cement, R. J. Colony. Min. & Metallurgy, no. 169, Jan. 1921, pp. 30–31, 1 fig. Triangular concentration diagram showing end products of consolidation. (Abstract.)

Specifications. British Standard Specification for Portland Cement. Eng. World, vol. 18, no. 1, Jan. 1921, pp. 5–8, 4 figs. Specifications of British Standards Engineering Association, revised in 1920.

Wet Process. Development in Wet Process Portland Cement Plants—II. Rock Products, vol. 24, no. 2, Jan. 15, 1921, pp. 39–44, 12 figs. Description of process at plant of Bessemer Limestone & Cement Co., Bessemer, Pa., from kilns to finished product.

CENTRAL STATIONS

Isolated Plants vs. Power Development in the Future, Lazarovich-Hrebellianovich. Power, vol. 52, no. 19, Nov. 9, 1920, pp. 744–747. Comparative study of central stations and isolated plants.

Mineside. Modern Central Power Station in Center of a Coal Mining District, F. G. Hickling. Coal Industry, vol. 4, no. 1, Jan. 1921, pp. 24–27, 7 figs. Riversville Central Station of Monongahela Valley Traction Co., Fairmont, W. Va. Two 12,500-kva. turbine generator units have been installed and additional 25,000 kva. unit has been ordered.

Operation in U. S. Output for 1920 Estimated at 46,700,000,000 Kw-Hr. Elec. World, vol. 77, no. 1, Jan. 1, 1921, pp. 45–46, 2 figs. Statistics of central station operations in United States.

CHIMNEYS

Steel, Copper-Smelter. Steel Chimneys and Their Linings in Copper Smelting Plants, A. G. McGregor. Min. & Metallurgy, no. 167, Nov. 1920, p. 34. It is concluded from experiments at various plants that unlined steel chimneys do not give satisfactory service when used for roaster furnaces or reverberatory furnaces, but they will prove serviceable for long periods when used for blast furnace and converter gases. Building tile has proved unsatisfactory for chimney linings or for construc-

tion of walls for flues and dust chambers where exposed to roaster furnace gases or cool reverberatory furnace gases. (Abstract.)

COAL

Pulverized. See PULVERIZED COAL.

Utah, Coking Properties. Low-Temperature Coking of Utah Coals, Osborn Monnett. Chem. & Metallurgical Eng., vol. 23, no. 26, Dec. 29, 1920, pp. 1246–1249, 2 figs. Summarized description of laboratory investigations made to determine coking property of series of Utah coals. Analysis of coals tested. Apparatus used. Tabulated results obtained.

COAL HANDLING

Hydraulic Conveyors. Conveying Bulk Material Through Pipes, George Frederick Zimmer. Eng. & Indus. Management, vol. 4, no. 25, Dec. 16, 1920, pp. 791–792, 3 figs. Scheme for handling coal hydraulically.

Power Plants. Fuel Handling. Power Plant Eng., vol. 25, no. 1, Jan. 1, 1921, pp. 2–14, 19 figs. Comparison of various methods of handling fuel economically in power plant.

New Station at Baltimore Has Unique Coal-Handling Method, M. D. Engle. Elec. World, vol. 77, no. 3, Jan. 15, 1921, pp. 133–137, 7 figs. How coal, received by water is handled at Westport Station. Method of load division with holtwood hydroelectric plant. Provision against generator fires and ceiling condensation among other features.

COAL STORAGE

Methods. Coal Storage. Power Plant Eng., vol. 25, no. 1, Jan. 1, 1921, pp. 14–23, 13 figs. Methods of storing coal in piles in the open, and arrangement of conveyors to carry coal to plant.

COAL TIPPLES

Construction. Mine of the Washington Gas Coal Company and Advances in Tipple Construction, J. O. Durkee and Frank A. Dowling. Coal Industry, vol. 4, no. 1, Jan. 1921, pp. 11–12 and 74–76, 5 figs. Tipple is arranged to coal locomotives, ship by truck or rail and supply Tyrler Tube Co. located near tipple.

COKE

Blast-Furnace. Determination of the Hardness of Blast-Furnace Coke. Owen R. Rice. Min. & Metallurgy, no. 167, Nov. 1920, pp. 34–35. Soft coke is deprecated for proper blast furnace operation. Methods of measuring coke hardness. (Abstract.)

House Heating with. By-Product Coke, Anthracite, and Pittsburgh Coal as Fuel for Heating Houses, Henry Kreisinger. Jl. Indus. & Eng. Chem., vol. 13, no. 1, Jan. 1921, pp. 31–33, 1 fig. Based on tests made at fuel laboratory of Bureau of Mines, Pittsburgh.

Metal Melting with. Coke and By-Products as Fuels for Metals Meltings, F. W. Sperr, Jr. Min. & Metallurgy, no. 167, Nov. 1920, p. 33. Growth of use of coke-oven tar as metallurgical fuel during past few years. With properly selected coals, modern by-product coke plant will produce straight gas having heating value of 560 B.t.u. per cu. ft. after removal of benzols. (Abstract.)

COKE MANUFACTURE

By-Product. By-Product Coking, F. W. Sperr, Jr., and E. H. Bird. Jl. Indus. & Eng. Chem., vol. 13, no. 1, Jan. 1921, pp. 26–31. Comparison of by-product and beehive ovens.

COKE OVENS

By-Product. By-Product Coke Oven Plants of Yesterday and Today, J. M. Hastings, Jr. Coal Industry, vol. 4, no. 1, Jan. 1921, pp. 44–47, 6 figs. Progress of art in 28 years as illustrated by old and new plants of Semet-Solvay Co.

Jones and Laughlin New By-Products Plant. Coal Industry, vol. 4, no. 1, Jan. 1921, pp. 47–51, 1 fig. Plant consists of five batteries of 60 ovens each of Koppers crossed regenerative type.

The By-Product Coke Oven Industry, 1920, D. J. Ramsburg. Coal Industry, vol. 4, no. 1, Jan. 1921, p. 52. First large battery of triangular flue type ovens completed and successfully operated during year.

COMBUSTION

CO_2 Recorders. The Unograph—An Automatic Continuous Analyzer without Chemical Absorption (L'"Unographe," analyseur continu et automatique sans absorption chimique), J. Izart. Chaleur et Industrie, no. 7, Oct. 1920, pp. 433–435, 3 figs. Principle and operation of Dommer CO_2 recorder.

CONCRETE, REINFORCED

Bond Resistance. Tests of Bond Resistance Between Concrete and Steel, W. A. Slater, F. E. Richart and G. G. Scofield. Technologic Papers, Bur. of Standards, no. 173, Nov. 1, 1920, 66 pp., 79 figs. Results of three dissimilar investigations which were made by concrete ship section of Emergency Fleet Corporation. One investigation was made to study effect on bond resistance of applications of various anticorrosive coatings on reinforcement; second investigation was made to study length of lap required for effective splicing of reinforcing bars in regions of high tensile stress; third investigation was made to study relative merits of different methods of anchoring ends of stirrups to meet certain conditions which arise in concrete ship construction.

CONDENSERS, STEAM

Naval Uses. Service Experience with Condensers, G. B. Allen. Power, vol. 52, no. 23, Dec. 7, 1920, pp. 914–916, 2 figs. Experience of British Admiralty. (Abstract.) Paper read before Inst. of Metals.

CONTRACTS

Cost-Plus. Cost-Plus Contracts, J. C. Keith. Jl. Eng. Inst. Canada, vol. 4, no. 1, Jan. 1921, pp. 8–11. Explanation of differences between cost-plus and unit-price form of contract, advantages and disadvantages, with examples of contracts on cost-plus basis.

CONVEYORS

Belt. General Types of Belt Conveyors, S. C. DeWitt. Can. Manufacturer, vol. 41, no. 1, Jan. 1921, pp. 62–64, 5 figs. Suitability of various types for different materials.

Factories. Conveyance in Workshop (Werkstättentransporte). Betrieb, vol. 3, no. 5, Dec. 10, 1920, pp. 37–38. Preliminary program prepared by the Committee for Economic Production dealing with following subjects: Determination of fundamental principles for economical use; establishment of useful sphere of hand and motor conveyors; adaptation of conveyor to its particular useful sphere, etc.

Foundry. Foundry Conveyor Equipment Offers Ideas for Adaptation Elsewhere, Norman G. Shidle. Automotive Industries, vol. 43, no. 26, Dec. 23, 1920, pp. 1274–1277, 9 figs. Methods of handling castings and other materials by means of various types of conveyors in foundry of Hercules Gas Engine Co.

Gravity. The Gravity Conveying System, L. T. Sylvester. Can. Manufacturer, vol. 41, no. 1, Jan. 1921, pp. 70–71, 9 figs. Typical installation.

Installations. A Highly Efficient Conveying Plant (Eine Förderanlage von hoher Wirtschaftlichkeit), G. Schlesinger. Zeit. des Vereines deutscher Ingenieure, vol. 64, no. 46, Nov. 13, 1920, pp. 949–953, 21 figs. Details of a mechanical hauling arrangement by means of which loading and unloading work at a drying plant for rifle stocks formerly requiring more than a hundred men can be carried out by two men. Notes on arrangement and manipulation of special cages and description of the drying plant.

COPPER METALLURGY

Smelter Stacks. See CHIMNEYS.

CORES

British Foundry Practice. Core Making Practice In Britain. Foundry, vol. 49, no. 2, Jan. 15, 1921, pp. 69–71, 9 figs. Cores employed to form exterior as well as interior of castings are recognized as economical factor in reducing cost of molding.

COST ACCOUNTING

Charts. How Graphics Help in Estimating Costs, J. B. Carr. Indus. Management, vol. 61, no. 1, Jan. 1, 1921, pp. 41–44, 4 figs. Method is illustrated by applying it to determine cost of Scotch boilers of various styles and sizes.

Making Statistics Talk—II, M. C. Rorty. Indus. Management, vol. 61, no. 1, Jan. 1, 1921, pp. 45–50, 13 figs. Exemplifies values and importance of charts in cost accounting.

Comparative Records. Comparative Cost Records as an Aid to Manufacturing Profits, Stephen R. Gordon. Indus. Management, vol. 61, no. 1, Jan. 1, 1921, pp. 17–22, 13 figs. How attention to details, such as decreasing waste in cutting cloth in textile mill and irregular stretching in dye house effected savings of more than $16,000 a year.

Overhead Expense. Machine-Hour Rate Method of Distributing Manufacturing Expense, C. Haigh. Machy. (N. Y.), vol. 27, no. 4, Dec. 1920, pp. 370–372. Comparison of man-rate and machine-hour rate method of considering overhead expense. Paper read before Am. Gear Manufacturers' Assn.

COTTON

Finishing Plants. Power Applications to Cotton-Finishing Plants, Leo Loeb. Mech. Eng., vol. 43, no. 1, Jan. 1921, pp. 5–8, 7 figs. Generation of power and of steam and applications to driving of process machinery are traced from boilers to motor applications. Charts are presented showing steam consumption and proportion of exhaust steam converted into work and available at exhaust for different types of prime movers. Illustrations of typical drives are included.

CRANES

I-Beam Girders. Properties of Crane Girder Sections, John H. Sawkins. Eng. News-Rec., vol. 86, no. 1, Jan. 6, 1921, p. 13, 2 figs. Table of mechanical properties of I-beam crane girders with lateral stiffening channels.

Long-Span. A New Form of Long-Span Crane. Engr. vol. 130, no. 3391, Dec. 24, 1920, pp. 631–632, 5 figs. General feature is that although crane has overhead girder spanning site of its operations, load is not carried directly by this girder, but by cableway attached to its two ends.

Pontoon. Huge Pontoon Crane. Pacific Mar. Rev., vol. 18, no. 1, Jan. 1921, pp. 30–31, 3 figs. Self-propelled 200-ton pontoon crane built by A. F. Smulders Corp., Holland.

Ship. A 250-Ton Ship Crane for the United States Navy, A. F. Case. Pacific Mar. Rev., vol. 18, no. 1, Jan. 1921, pp. 29–30, 4 figs. Revolving crane to be mounted on hull of U. S. Battleship Kearsarge.

CUTTING TOOLS

Construction. Metal Cutting Tools, A. L. De Leeuw. Am. Mach., vol. 54, no. 1, Jan. 6, 1921, pp. 1–7, 21 figs. Analogy between actions of razor, hatchet and metal cutting tools. Formation of chips. Elementary considerations in construction of simple tools.

Grinding. Grinding Lathe and Planer Tools. Machy. (Lond.), vol. 17, no. 432, Jan. 6, 1921, pp. 418–420, 2 figs. correct angle to use when grinding. Power consumption for different angles and position of lathe tools.

Inserted Cutters. The "Herbert" Patent High Duty Inserted Tooth Face Cutter. Practical Engr., vol. 62, no. 1766, Dec. 30, 1920, pp. 420–422, 5 figs. Invention is applicable to milling cutters, boring bars and generally wherever body of tool may be made of softer steel than that of tooth.

Screw Threads. Spring Tool for Cutting Threads. Iron Age, vol. 107, no. 3, Jan. 20, 1921, p. 208, 1 fig. Tool utilizes goose-neck principle to eliminate chatter and permit cutting of smooth threads on lathe work.

CYLINDERS

Castings. Make Marine Cylinders in New Shop, Herbert R. Simonds. Foundry, vol. 49, no. 1, Jan. 1, 1921, pp. 1–4, 7 figs. Making of castings at Boston Navy Yard.

Manufacture. Cylinder Blocks Manufactured in an Efficient Manner, J. Edward Schipper. Automotive Industries, vol. 44, no. 2, Jan. 13, 1921, pp. 72–77, 14 figs. Manufacturing process used in machining cylinder block castings for Lexington car.

D

DIES

Compound. Compound Blanking, Forming and Piercing Die, F. H. LeJeune. Machy. (N. Y.), vol. 27, No. 5, Jan. 1921, pp. 441–442, 3 figs. Die for producing tractor-wheel spoke covering one operation.

Locomotive Parts. Special Railroad Machine-Forging Tools, J. V. Hunter. Am. Mach., vol. 54, no. 2, Jan. 13, 1921, pp. 67–68, 7 figs. Description of dies used for forging locomotive grease cups, universal-joint jaws, connecting rods, valve handles, boiler-flue beading tools, etc.

Seamless Kettles. Drawing Operations on Seamless Kettles, Fred R. Daniels. Machy. (N. Y.), vol. 27, no. 5, Jan. 1921, pp. 433–437, 18 figs. Design of dies and step-by-step operations in making difficult drawn shape.

DIESEL ENGINES

Diesel-Sulzer. Diesel-Sulzer Two-Cycle Motor Exhibited at Crystal Palace Great War Exhibition in London (Moteur Diesel-Sulzer à deux temps., au Great War Exhibition du Crystal Palace, à Londres). Bulletin technique de la Suisse romande, vol. 46, no. 23, Nov. 13, 1920, pp. 265–267, 4 figs. Effective power is 425 hp. at speed of 200 r.p.m.; fuel consumption varies from 195 to 200 grams per effective horse-power-hour. Engine is directly reversible.

Doxford. The Doxford Diesel Engine. Eng., vol. 110, no. 2869, Dec. 24, 1920, pp. 838 and 845–846, 2 figs. Opposed piston solid injection two-cycle reversible marine oil engine.

German Submarine. Modern German Submarine Diesel Engines (Neuere deutsche Unterseeboots-Dieselmaschinen), Max Wilh. Gerhards. Motorwagen, vol. 23, no. 27, Sept. 30, 1920, pp. 512–519, 8 figs. Details and data of construction and operation of different types of submarine oil engines built by the Machine Factory Augsburg-Nürnberg (M. A. N.).

Solid-Injection. The Solid Injection Engine, C. McTaminey. Trans. Inst. Mar. Engrs., vol. 32, Nov. 1920, pp. 161–178 and (discussion) pp. 179–194, 4 figs. Details of construction of Diesel marine installations developed by British Admiralty during war.

DOCKS

Testing U-Boats. German Marine Testing Dock (Prüfdock für die Deutsche Marine), H. Klitzing. Zeit. des Vereines deutscher Ingenieure, vol. 64, no. 51, Dec. 18, 1920, pp. 1074–1079, 19 figs. Dock built 1916–1918 for testing U-boats consists of a supporting pontoon, side compartments for insuring position of equilibrium, and a 116-m. pressure cylinder for housing of test boat, which has internal diameter of 12 m.; on both sides of the freely mounted pressure cylinder is room for docking two additional boats. Description of entrance shaft to test boat, manholes of pressure cylinder, pump plant, etc.

DRILLING MACHINES

Automatic. Automatic Drilling Machine with Gravity Feed. (Machy. Lond.), vol. 17, no. 431, Dec. 30, 1920, pp. 396–397, 2 figs. Each of two spindles operates independently, and feeding of drill into work is accomplished by weight which exerts constant feeding pressure during drilling operation.

Radial. Large Radial Drilling Machines. Eng. Production, vol. 2, no. 14, Jan. 6, 1921, pp. 22–23, 1 fig. Designed for use on large turbine work.

DRILLS

Twist. Helix Angle of Twist Drills, Bruce W. Benedict. Am. Mach., vol. 53, no. 26, Dec. 23, 1920, pp. 1175–1178, 5 figs. Concludes from experiments that with present design of flute, most efficient high-speed milled twist drill has helix angle of 35

Action, Theory of. Theory of Dust Action, C. ... Armspach. Jl. Am. Soc. Heat. & Vent. Engrs., vol. 26, no. 9, Dec. 1920, pp. 819–829, 6 figs. Report upon investigations carried out jointly by Research Bureau & U. S. Bureau of Mines. It is shown that dust content in room depends upon density of material, velocity of fall of particles and size of room; dust will accumulate until definite content is reached depending upon rate of fall and number of air changes.

DYNAMOMETERS

Variable-Speed. A Variable Speed Fan Dynamometer, Karl D. Wood. Aerial Age, vol. 12, no. 19, Jan. 17, 1921, pp. 491–492, 4 figs. Apparatus designed by automotive power-plant section of Bureau of Standards.

E

ECONOMIZERS

Installation. Economizers, W. F. Wurster. Jl. Am. Soc. Heat. & Vent. Engrs., vol. 26, no. 9, Dec. 1920, pp. 811–818, 6 figs. Typical installations of economizers in steam power plants.

Operation. Two Useful Suggestions in Regard to Operation of Economizers (Deux points utiles à connaître concernant les économiseurs), Henry Dieterlen. Chaleur & Industrie, no. 8, Nov.-Dec. 1920, pp. 487–489, 3 figs. How to prevent trouble in pumps arising from hot water used, and how to prevent vapor condensation on outside of economizer.

EDUCATION, INDUSTRIAL

Coöperative High-School Course. The Industrial Coöperative Course of the Lansing High School, E. M. Hall. Am. Mach., vol. 54, no. 3, Jan. 20, 1921, pp. 83–86, 13 figs. Course, open to youths of city of Lansing, intended to provide thorough training and experience in technical trades.

[See also VOCATIONAL EDUCATION.]

ELECTRIC DRIVE

Refrigerating Plants. Electric Drive for Ice Making and Refrigerating Plants, William J. Bray. Ice & Refrigeration, vol. 60, no. 1, Jan. 1921, pp. 23–25, 3 figs. Types of apparatus.

[See also ROLLING MILLS, Electrically Driven.]

ELECTRIC FURNACES

Annealing. Electric Annealing and Heat Treating Furnaces, George P. Mills. Jl. Engrs. Club of Phila., vol. 38–1, no. 193, Jan. 1921, pp. 25–31, 6 figs. Ni-chrome resistor type of electric furnace. Operating data on typical installations and probable trend of new applications.

Brass. New Casting Shop of the Bridgeport Brass Company, H. M. Lane. Metal Industry (N. Y.), vol. 19, no. 1, Jan. 1921, pp. 1–3, 5 figs. Construction and method of operation of shop running entirely on electric furnaces.

Booth Rotating. Booth Rotating Electric Brass Furnace. Metal Industry (Lond.), vol. 17, no. 26, Dec. 24, 1920, pp. 507–508. Features of later designs. Automatic electrode control.

Iron-Smelting. Swedish Electric Pig Iron Furnaces, Jonas Herlenius. Chem. & Metallurgical Eng., vol. 24, no. 3, Jan. 19, 1921, pp. 108–112, 3 figs. Description of Swedish electric furnace and summary of results obtained from its use.

Refractories for. Refractories for Electric Furnace, R. M. Howe. Chem. & Metallurgical Eng., vol. 23, no. 25, Dec. 22, 1920, pp. 1215–1218. Description of properties of refractory brick and of raw materials employed in their manufacture, with review of many factors involved in efficient use of refractories in general. Paper read before Elec. Furnace Assn.

Synthetic Pig Iron. See PIG IRON, Synthetic.

Uses. Electric Furnace Usage Fast Increasing. Elec. World, vol. 77, no. 2, Jan. 8, 1921, pp. 77–79, 3 figs. More than 220 non-ferrous furnaces installed during 1920. Total connected furnace load estimated at 880,000 kva., of which 410,000 kva. is in commercial furnaces. Electric steel output reduced.

ELECTRIC LOCOMOTIVES

C. M. & St. P. New Electric Passenger Locomotives in Operation on the C. M. & St. P. Railway, W. H. Munn. Jl. Western Soc. Engrs., vol. 26, no. 1, Jan. 1921, pp. 26–29, 2 figs. Characteristics: Total weight, 275 tons; number of driving axles, 6; classification, 4–6–2–2–6–4; tractive effort, continuous rating, 49,000 lb.; speed maximum, 65 m.p.h.

Switzerland. The Locomotives of the Swiss Railways (Les locomotives des chemins de fer rhetiques), Lucien Pahin. Revue générale de l'Électricité, vol. 8, no. 25, Dec. 18, 1920, pp. 872–878, 8 figs. Details of electric locomotives of Brown Boveri & Co.

ELECTRIC PLANTS

Interconnection. Coöperation for the Central Station and Isolated Plant. Elec. World, vol. 77, no. 1, Jan. 1, 1921, p. 11. Interconnection is economically sound and is shown to hold mutual advantages where isolated plants can be justified.

ELECTRIC WELDING, ARC

Boiler Repairing. The Electric Welding of a Corroded Boiler-Shell, A. Kenneth Dawson. Trans.

Car-Truck Frame. Arc Welding on Railway Properties, A. M. Candy. Elec. Ry. Jl., vol. 57, no. 3, Jan. 15, 1921, pp. 121–124, 17 figs. Truck frames manufactured by Government Electric Railways of Sydney, Australia, and other examples of applications of electric welding in manufacture of railway cars.

Equipment. Electric Welding, William T. Bonner, A. A. Nims, C. J. Holslag and H. E. Dralle. Jl. Engrs. Club of Phila., vol. 38–1, no. 193, Jan. 1921, pp. 7–23, 8 figs. Notes on selection of arc-welding equipment and fundamentals of its efficient operation.

Practice. Arc Welding Practice. J. H. Anderton. Jl. Elec., vol. 45, no. 12, Dec. 15, 1920, pp. 572–574. Greater flexibility and better control in arc welding are obtained by use of metal instead of carbon electrode. Records of tensile tests of welds are included.

The Welding of Metals by the Electric Arc (La soudure des différents métaux par l'arc électrique), Ch. Andry-Bourgeois. Électricien, vol. 51, no. 1266, Dec. 15, 1920, pp. 536–539, 1 fig. Welding of bronzes and aluminum alloys. (Continuation of serial.)

Steel. Electric-Arc Welding of Steel: I. Properties of the Arc-Fused Metal, Henry S. Rawdon, Edward C. Groesbeck and Louis Jordan. Technologic Papers, Bur. of Standards, no. 179, Nov. 15, 1920, 63 pp. 28 figs. Research to determine in empirical way by actual welding tests carried out by skilled operators relative values and merits of different types of electrodes which are available commercially.

ELECTRICAL INDUSTRY

Developments in 1920. Some Developments in the Electrical Industry During 1920, John Liston. Gen. Elec. Rev., vol. 24, no. 1, Jan. 1921, pp. 4–49, 99 figs. Developments in turbo-generators, electric locomotives, electrical machinery, electric cranes, hoists, transformers, insulators and electric lighting.

EMPLOYEES' REPRESENTATION

Shop Committees. A Shop Committee that Failed, O. F. Carpenter. Indus. Management, vol. 61, no. 1, Jan. 1, 1921, pp. 59–62. Experience of one firm that introduced industrial democracy.

Works Councils. Works Council after Two Years' Trial. Can. Machy., vol. 24, no. 27, Dec. 30, 1920, pp. 597–600, 6 figs. Experience of International Harvester Co.

EMPLOYMENT MANAGEMENT

Selecting Employees. Fewer Mistakes in Selecting Employees, William S. Dutton. Factory, vol. 26, no. 1, Jan. 1, 1921, pp. 38–39, 2 figs. Experiences of E. I. duPont de Nemours & Co.

ENGINEERING SOCIETIES

Progress in 1920. Progress of Engineering Societies in 1920, Calvin W. Rice. Power, vol. 53, no. 1, Jan. 4, 1921, pp. 22–23. Outstanding event is establishment of Federated American Engineering Societies which typifies "unselfish devotion on the part of the engineering profession to the good of the community and the nation."

ENGINEERS

Registration. Code of Practice and Schedule of Fees for Structural Engineers. Eng. & Contracting, vol. 54, no. 25, Dec. 22, 1920, pp. 603–605. Proposed code of practice for use of members of Structural Engineers' Association of Illinois prepared by committee of association.

Engineering Legislation for Out. Contract Rec., vol. 35, no. 2, Jan. 12, 1921, pp. 39–44. Draft bill for registration of engineers, drawn up by Advisory Conference Committee representing civil, mechanical, electrical and mining engineers.

Engineering Legislation in Canada, Fraser S. Keith. Eng. News-Rec., vol. 86, no. 1, Jan. 6, 1921, pp. 21–24. Outline of history of movement for statutory control of professional practice, with synopsis of acts passed by provinces.

Saskatchewan's "Engineering Profession Act." Can. Engr., vol. 39, no. 25, Dec. 16, 1920, pp. 615–618. Text of bill that has been introduced in Saskatchewan Legislature.

Remuneration. Fees and Services of Practicing and Consulting Engineers, W. L. Benham. Eng. News-Rec., vol. 85, no. 27, Dec. 30, 1920, pp. 1266–1267. Report of Committee on fees and services of practicing engineers of American Association of Engineers.

The Engineering Profession and Government Technology, R. S. McBride. Chem. & Metallurgical Eng., vol. 23, no. 26, Dec. 29, 1920, pp. 1265–1267, 3 figs. Need for increasing salaries of government professional employees is brought out by enumeration of series of facts on conditions now existing in different government technical bureaus.

Social Functions. The Engineer's Service to Society, Fred J. Miller. Mech. Eng., vol. 43, no. 1, Jan. 1921, pp. 1–4 and 8. Discusses influence of engineer in constructive adjustment, property rights and human rights and relations between employer and employee. Presidential address at Annual Meeting of Am. Soc. Mech. Engrs.

ENGINEHOUSES

Design. Modernizing Locomotive Terminals, G. W. Rink. Mech. Eng., vol. 43, no. 1, Jan. 1921, pp. 13–16, 5 figs. Location, size and general layout in this subject, which has important bearing on ability of railroads to handle increased traffic demands of country.

EXECUTIVES

Industrial. The Executive—and Today's Problem, Lewis E. Pierson. Indus. Management, vol. 61, no. 1, Jan. 1, 1921, pp. 7–8 and p. 50 and 57–58. Suggestions to executives in regard to present business conditions.

F

FACTORIES

Oversize Construction. Oversize Construction Plant Demonstrates Value. Eng. News-Rec., vol. 86, no. 2, Jan. 13, 1921, pp. 82–85, 4 figs. Automobile body factory at Cleveland, Ohio, completed in quick time by concentrating equipment for peak-load construction.

FACTORY MANAGEMENT

See INDUSTRIAL MANAGEMENT

FARM MACHINERY

Electrically Operated. Electric Farming (Le labourage électrique). Bulletin de la Société Française des électriciens, vol. 10, no. 86, Feb. 1920, pp. 57–78, 11 figs. Electric winch for operating plow, and other electrically operated machinery, together with portable transformer for taking power at various points of line.

London Show. The Smithfield Club Show. Engr., vol. 130, no. 3389, Dec. 10, 1920, pp. 582–583, 6 figs. Details of farm machinery exhibited at London Show.

FATIGUE

Blast-Furnace Men. Fatigue of Blast-Furnace Men. Iron & Coal Trades Rev., vol. 101, no. 2757, Dec. 31, 1920, pp. 910–911. Report issued by Committee of Industrial Fatigue Research Board, England.

FERROALLOYS

Iron-Vanadium. The Magnetizability of Iron-Vanadium Alloys (Die Magnetisierbarkeit von Eisen-Vanadium-Legierungen), R. Dieterle. Archiv. fur Elektrotechnik, vol. 9, no. 7, Nov. 8, 1920, pp. 314–318, 2 figs. Results of author's measurements are presented in curves and tables, from which it is concluded that vanadium has the same effect as silicon and aluminum on the magnetic properties of iron and could, therefore, be taken into consideration for the production of so-called alloyed sheet metals.

FIRE PREVENTION

Pulpwood Piles. Fire Prevention in Pulp Wood Piles, F. J. Hoxie. Paper, vol. 27, no. 15, Dec. 15, 1920, pp. 13–19, 13 figs. Spray nozzles forming artificial fog for protection of piles of pulpwood.

FLIGHT

Soaring. Soaring Flight (Le vol a voile), P. Idrac. Nature (Paris), no. 2434, Nov. 27, 1920, pp. 347–349. Forces acting.

Soaring Flight (Sur le probleme du vol à voile), Jean Constantin. Aéronautique, vol. 2, no. 18, Nov.-Dec. 1920, pp. 251–255, 3 figs. Theory of forces acting. Support of bird is found to depend on resultant of mass on wings, action of wind against inclined plane of body and curved surface of wings, and greater inertia of moving air.

The Gliding and Soaring Flight Contest in the Rhön Mountains (Der Gleit- und Segelflug-Wettbewerb in der Rhön), Ferdinand Trendelenburg. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol. 11, no. 20, Oct. 30, 1920, pp. 295–297, 1 fig. Account of flights and details of aeroplanes figuring in contest. Report of the German Experimental Inst. for Aeronautics.

The Soaring Flight of Birds, Leon Bollee. Aerial Age, vol. 12, no. 16, Dec. 27, 1920, pp. 421, 3 figs. Study of forces acting.

FLOW OF AIR

Conduits. Measurement of Quantity of Air Flowing Through a Conduit (La mesure des débits de vent), M. Lebrasseur. Chaleur & Industrie, no. 8, Nov.-Dec. 1920, pp. 474–477, 5 figs. Measurement by means of venturi is preferred.

FLOW OF STEAM

See FLOW OF WATER, Transmission Wastes

FLOW OF WATER

Concrete Pipe Lines. Flow of Water in Concrete Pipe Lines. Can. Engr., vol. 40, nos. 1 and 2, Jan. 6–13, 1921, pp. 101–105, 2 figs., and 124–126, 3 figs. Test data showing effect of variations in character and condition of pipe on coefficients of retardation for various formulæ. Test of big conduit at Niagara Falls.

Dredge Pipes. Velocity Tests in Hydraulic Dredge Pipe, Ivan E. Houk, Eng. News-Rec., vol. 86, no. 1, Jan. 6, 1921, pp. 18–19, 1 fig. Description of apparatus for measuring velocity of dredge pipe discharge, and tables of results obtained.

Transmission Wastes. Transmission Wastes. Power Plant Eng., vol. 25, no. 1, Jan. 1, 1921, pp. 85–93, 11 figs. Chart of flow of water in pipes and loss of head by friction, also for determining loss of steam pressure per 100 ft. of pipe.

FLUE-GAS ANALYSIS

Graphical Method. A Graphical Method for the Interpretation of Flue Gas Analyses, Gilbert B. Howarth. Jl. Soc. Chem. Industry, vol. 39, no. 24, Dec. 31, 1920, pp. 329T–333T, 3 figs. Construction of diagram and its use for commercial purposes.

FLYWHEELS

Stresses in. Resistance of a Disk Subjected to Rapid Rotation (De la résistance des disques à rotation rapide), L. Anspach. Bulletin technique de l' Association des Ingénieurs sortis de l'École Polytechnique de Bruxelles, vol. 14, no. 1, 1920–1921, pp. 21–54, 1 fig. Fundamental formula developed in general case and applied to design and study of flywheels.

FORGING

Brass. Making Brass Forgings. Machy. (Lond.), vol. 17, no. 430, Dec. 23, 1920, pp. 341–346, 10 figs. Methods developed by Mueller Metals Co. in metal working.

Furnaces. The Construction of Ducts for Forge Exhaust and Blast Systems. Heat. and Vent. Mag., vol. 17, no. 12, Dec. 1920, pp. 35–39, 8 figs. Furnace installation at plant of General Vehicle Co., Long Island City.

Steel. The Forging of Steel and Fundamental Principles for the Design of Steam and Drop Hammers (Das Schmieden des Stahls und die Grundlagen zur Bemessung von Hämmern und Fallwerken), Erich Siebel. Werkstattstechnik, vol. 14, nos. 18, 20 and 21, Sept. 15, Oct. 15 and Nov. 1, 1920, pp. 492–496, 529–532 and 566–569, 17 figs. After a brief discussion of metallurgical conditions in connection with forging and annealing, the machine equipment for hot forging is discussed. Investigation of the pheuomena occurring with die forging and swaging, and especially of the relation between existing experimental results and operating experiences on one hand and the theoretical considerations on the other.

FOUNDRIES

Aluminum. Analyze Loss in Aluminum Shops—III, Robert J. Anderson. Foundry, vol. 49, no. 2, Jan. 15, 1921, pp. 54–57, 2 figs. Conditions at several typical foundries described, including melting equipment and operation molding methods and inspection routine. Pyrometric control varies in different foundries.

Conveying Equipment. See CONVEYORS, Foundry.

Layout. Foundry Planning by Example, Charles K. Sumner. Metal Trades, vol. 12, no. 1, Jan. 1921, pp. 14–15. Data on twelve existing gray iron foundries in San Francisco and vicinity.

Scrap Recovery. Economy in the Recovery of Scrap in Iron and Steel Foundries (Ueber die Wirtschaftlichkeit der Rückgewinnung des Abeisens in Eisen- und Stahlgiessereien), Hubert Hermanns. Betrieb, vol. 3, no. 3, Nov. 10, 1920, pp. 66–67, 1 fig. Includes tabular data compiled from four different plants showing net production costs of recovered scrap, and curves showing results of calculation of operating costs.

[See also CORES.]

FUELS

Briquets from Wastes. Manufacture of Briquets from Waste Fuels (Brikettierung von Abfallbrennstoffen), Otto Brandt. Betrieb, vol. 3, no. 3, Nov. 10, 1920, pp. 72–76, 5 figs. For making briquets from waste wood, tan bark and garbage a process which does not employ a binder is described, also one with a binder for making briquets from coke, coal, lignite, flue and smoke-box dust, slag residue, etc. Profitableness of such briquet plants for use of waste material is discussed.

Colloidal. Colloidal Fuel as Developed by the Submarine Defense Association of New York. Power Plant Eng., vol. 25, no. 1, Jan. 1, 1921, pp. 55–56, 2 figs. Chart giving comparative savings effected with colloidal fuel.

Colloidal Fuels, Their Preparation and Properties, S. E. Sheppard. Jl. Indus. & Eng. Chem. vol. 13, no. 1, Jan. 1921, pp. 37–47, 12 figs. Survey of developments.

Conservation. Fuel and its Conservation, L. P. Breckenridge, O. P. Hood, David Moffat Myers and Chester G. Gilbert and Joseph E. Pogue. Mech. Eng., vol. 43, no. 1, Jan. 1921, pp. 22–28 and (discussion) pp. 28–31 and 38. Group of papers dealing with fuel supply of world, fuel conservation, distillation of fuels, and form value of energy, with discussion thereon, which were presented at 1920 Annual Meeting of Am. Soc. Mech. Engrs.

Economical Use. Rational Utilization of Fuels (L'utilisation rationnelle des combustibles), Georges Charpy, Emilio Damour, E. De Loisy, M. Ader, Ch. Berthelot. Mémoires et Compte rendu des Travaux de la Société des Ingenieurs civils de France, vol. 73, nos. 4, 5 and 6, April-June, 1920, pp. 245–393. Symposium on fuel economy. Principles of economic composition of various fuels, gaseous, liquid and solid. Suggestions in regard to their economic utilization in industrial works.

Oil. See OIL FUEL.

Patented Mixtures. Improvements in Furnace Installations for Hard Fuels (Neuerungen an Feuerungsanlagen für feste Brennstoffe), A. Pradel. Feuerungstechnik, vol. 9, no. 2, Oct. 15, 1920, pp. 13–17, 10 figs. Quarter-yearly report describing new foreign and domestic patents and innovations.

Turf. A New Process of Drying Turf for Fuel in Finland. Commerce Reports, no. 306, Dec. 30, 1920, p. 1359. Raw turf in swamp is freed from old roots and changed to thin mud by powerful jet of water under pressure of 20 atmospheres. This is pumped out on drying field and spread in layers from 20 to 30 centimeters in depth. When dry it is cut into bricks of uniform size by means of tractor.

[See also LIGNITES; PEAT; PULVERIZED COAL.]

FURNACES, BOILER

Design. New Patents for Steam-Boiler Furnaces (Neue Patente auf dem Gebiete der Dampfkesselfeuerung), A. Pradel. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 43, nos. 40 and 42–43, Oct. 1 and 22, 1920, pp. 305–310 and 323–326, 34 figs. Quarter-yearly report giving review of recently patented foreign and domestic devices.

Forced-Draft. Forced-Draft Furnaces (Unterwindfeuerungen), L. Schmitt. Zeit. des Verbandes Deutscher Diplom-Ingenieure, vol. 11, no. 17–18, Sept. 1–15, 1920, pp. 91–92. Information concerning operating costs of different types of undergrate blowers.

Lignite-Burning. The Adaptation of Steam-Boiler Furnaces to the Burning of Lignite (Umstellung von Dampfkesselfeuerungen auf Braunkohle), H. Berner. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 43, no. 42–43, Oct. 22, 1920, pp. 321–322. Points out advantages and disadvantages of the forced-draft horizontal grate.

Low-Grade Fuels. The Adaptation of Steam-Boiler Furnaces to Low-Grade Fuels (Die Umstellung der Dampfkesselfeuerungen auf minoerwertige Brennstoffe). Zeit. des Vereines deutscher Ingenieure, vol. 64, no. 51, Dec. 18, 1920, pp. 1069–1070. Full report published by the Board of Heat Conservation giving experiences recorded at the convention of Board in Berlin, September, 1920.

Stephens. Grateless, Smokeless, Automatic Furnace for Steam Power Production at the Mines. Coal Industry, vol. 4, no. 1, Jan. 1921, pp. 19, 1 fig. Patented process tested at Stephens laboratory, U. S. Bureau of Mines, Pittsburgh.

FURNACES, OPEN HEARTH

Waste-Heat Boilers. Application of Waste Heat Boilers to Open Hearth Furnaces, Thomas R. Tate. Assn. Iron & Steel Elec. Engrs., vol. 2, no. 12, Dec. 1920, pp. 1–6 and (discussion) pp. 6–10. Method of determining proper size and type boiler for any installation.

G

GAGES

Checking. Keeping an Accurate Check on Gages, J. Edward Schipper. Automotive Industries, vol. 43, no. 25, Dec. 16, 1920, pp. 1225–1227, 7 figs. Method of checking gages at plant of Lincoln Motor Co.

Measurement of. Two Apparatus for the Measurement of Threads and Gages (Zwei Apparate zur Messung von Gewinden und Lehren), F. Göpel. Werkstattstechnik, vol. 14, no. 21, Nov. 1, 1920, pp. 559–563, 15 figs. Description of a measuring machine with spirit-level gage for determination of pitch of thread; and an angle meter for chasing tools based on principle of the goniometer. Both instruments designed by author.

GAS ENGINES

Blast-Furnace Gas. Cockerill Blast-Furnace Gas Engines, H. Hubert. Engr., vol. 130, no. 3386, Nov. 19, 1920, pp. 495–498, 11 figs. Performance tests.

Design. Recent Improvements in Large Gas Engines (Les derniers perfectionnements aux moteurs à gaz de grande puissance), H. Feron. Vie technique & industrielle, vol. 2, no. 13, Oct. 1920, pp. 14–17, 7 figs. Design of special fixtures and attachments for gas engines of more than 1000 hp.

Vertical. 120 H. P. Vertical Gas Engine. Engr., vol. 130, no. 3388, Dec. 3, 1920, p. 567, 2 figs. Three-crank vertical engine with one cylinder, 13-in. bore and 14-in. stroke for each crank, and capable of giving constant output of 120 b.hp. on producer gas.

GASES

Volume Measurement. Methods of Measuring Large Volumes of Gases, specially Applicable to Gas and Coke Works (Méthods de mesure de grands volumes gazeux spécialement applicables aux usines à gaz et aux cokeries), M. C. Berthelot. Revue de Métallurgie, vol. 17, no. 10, Oct. 1920, pp. 668–676, 6 figs. Classification and comparison of practices in common use. Description of Nurgue volume-recording apparatus.

GASOLINE

Hecter Fuel. Comparison of Hecter Fuel with Export Aviation Gasoline, H. C. Dickinson, V. R. Gage and S. W. Sparrow. Nat. Advisory Committee for Aeronautics, report no. 90, 1920, 10 pp., 13 figs. Investigation conducted at altitude laboratory of Bureau of Standards. Hecter fuel is mixture of approximately 30 per cent benzol, 70 per cent cyclohexane by volume. For flight at low altitudes Hecter fuel showed slight advantages in comparison with gasoline by affording small increase of power over and above that necessary to offset disadvantage of increased fuel consumption. At 14,000 feet and 25,000 feet no appreciable difference in power was obtained, whereas fuel consumption of Hecter was greater to extent of 15 per cent by weight.

Natural Gas. Treating Natural-Gas Gasoline to Meet the "Doctor Test," D. B. Dow. Reports of Investigations, Bur. of Mines, Dept. of Interior, serial no. 2191, Dec. 1920, 4 pp. Basis for installation of economical treating process.

GASOLINE ENGINES

Exhaust Gases. Exhaust Gases of Petrol Engines. Times Eng. Supp., no. 554, Dec. 1920, p. 382. Methods of utilization.

Single Sleeve Valve. New Model of Single Sleeve Valve Engine. Automotive Industries, vol. 43, no. 26, Dec. 23, 1920, pp. 1270–1271, 2 figs. Burt-MacCullum engine manufactured by Argylls, Scotland, has been revived in improved and simplified form. Removable port liners used in cylinder. Valve is given combined oscillating and reciprocating motion. Heads are detachable.

Variable Clearance Volume. An Engine with Clearance Volume and Valve Timing Both Variable. Automotive Industries, vol. 43, no. 27, Dec. 30, 1920, pp. 1314–1315, 4 figs. Experimental engine has hydraulic device for raising and lowering crankshaft. Tests indicated considerable saving in fuel under normal operating conditions, but mechanical complications were involved.

GEARS

Bevel. Chordal Thickness of Tooth and Corrected Pitch Depth of Bevel Gears. Machy. (Lond.), vol. 17, no. 432, Jan. 6, 1921, pp. 423–424, 1 fig. Diagram showing dimensions and angles used in determining chordal thickness and corrected pitch depth of bevel gear teeth.

Horsepower Chart. Horsepower Chart for Gear Teeth. Machy. (Lond.), vol. 17, no. 430, Dec. 23, 1920, pp. 359–360, 1 fig. Chart for determining horsepower transmitted by gears when load is known.

Layout. Laying Out Gearing and Making Gear Patterns, H. J. M'Caslin. Can. Foundryman, vol. 12, no. 1, Jan. 1921, pp. 28–29, 3 figs. Study of gearing including spur, bevel and miter gears, involute and epicycloidal teeth, circular and diametral pitch and other features in connection with gearing.

Worm. The Efficiency of Worm-Gearing, W. S Atkinson. Machy. (N. Y.), vol. 27, no. 4, Dec. 1920, pp. 315–316, 2 figs. Formulæ for computing efficiency in various cases.

GRINDING

Cylindrical. Work Speeds in Cylindrical Grinding, Robert J. Spence. Machy. (N. Y.), vol. 27, No. 5, Jan. 1921, pp. 438–440. Importance of instructing operators concerning proper work speeds to be used. Results obtained by reducing work speed.

Pulverizing Hard Materials. Progress in the Fine Grinding of Hard Material, III and IV (Neuerungen der Hartzerkleinerung), Carl Naske. Zeit. des Vereines deutscher Ingenieure, vol. 64, nos. 47 and 52, Nov. 20 and Dec. 25, 1920, pp. 980–985 and 1109–1113, 43 figs. Nov. 20: Discussion of kilns. Notes on revolving tubular kilns and utilization of waste heat; enlarged calcination zones; revolving tubular vs. shaft kilns; automatic shaft kilns; suggestions for automatic discharge devices; problems of fuel admission and mixture; a recommendation for burning of lime; Dec. 25: Description of plant for pulverizing castiron turnings for an analine factory; lime- and coke-crushing plant for a carbide factory; super-phosphate factory; plant for grinding and drying ammonium nitrate; lime-burning plant; soda-treatment plant; and portland-cement mill.

GRINDING MACHINES

Surface. Wilmarth & Morman Company's No 78 Surface Grinding Machine. Am. Mach., vol. 54, no. 2, Jan. 13, 1921, pp. 41–42, 1 fig. Two precision screws used for adjusting wheel to cut. Clutch and all gears run in oil.

GUN METAL

Non-Corrodible. The Development of Non-Corrodible Gun Barrels. F. A. Fahrenwald. Monthly Bul. Can. Inst. Min. & Metallurgy, no. 105, Jan. 1921, pp. 27–48, 2 figs. Objections to present-day gun steels are pointed out and materials for purpose are suggested.

GUNS

Manufacture. A Method of Gun Construction by Radial Expansion, S. J. Brown. United States Naval Inst. Proc., vol. 46, no. 214, Dec. 1920, pp. 1941–1970, 11 figs. Principle is that if hollow thick tube is exposed to internal pressure great enough to stress all fibers to elastic limit. When pressure is removed external layers will shrink back on internal layers and leave them in state of compression.

H

HARDENING

Fire Cracks. Fire Cracks and Some of Their Causes. J. V. Emmons. Metal Trades, vol. 12, no. 1, Jan. 1921, pp. 22–25, 9 figs. From "Metal Heating" published by Tate, Jones & Co., Inc., furnace engineers, Pittsburgh.

HEAT PUMPS

Utilization of. The Heat Economy and Useful Forms of the Heat Pump (Wärmewirtschaft und Anwendungsformen der "Wärmepumpe"), Gustav Flügel. Zeit. des Vereines deutscher Ingenieure, vol. 64, nos. 46 and 47, Nov. 13 and 20, 1920, pp. 954–958 and 986–989, 14 figs. Equations are presented for determining the heat economy of different concentration processes, both old and new, with special regard to utilization of the vapors given off and it is explained in what forms the heat pumps can be utilized for different purposes.

Industrial Applications. Industrial Applications of Heat Treating (Les traitements thermiques dans leur application actuelle), Arnould De Grey. Chaleur et Industrie, no. 7, Oct. 1920, pp. 419–428, 1 fig. Recent progress in tempering and hardening processes.

Thermal Analysis. Industrial Apparatus for Thermal Analysis in Heat Treating (Appareil industriel d'analyse thermique), M. Pierre Chevenard. Revue de Métallurgie, vol. 17, no. 10, Oct. 1920, pp. 687–695, 8 figs. Apparatus registers, in terms of time, temperature of sample submitted to regular heat-treating process and then left to itself to cool.

HEATING AND VENTILATION

Museums. The Heating and Ventilation of Museums (Die Beheizung, Luftzu- und abführung und Luftbefeuchtung der Museen), H. Hasak. Gesundheits-Ingenieur, vol. 43, no. 43, Oct. 23, 1920, pp. 508–510. Writer describes system planned by him and adopted by the Kaiser-Wilhelm Museum in Berlin, Germany, where it has given great satisfaction, with regard to uniform heating, removal of dust from air, supplying moisture to air, etc.

Paper-Machine Rooms. Heating and Ventilation of Paper Machine Rooms, Edward A. Ryan. Jl. Eng. Inst. Canada, vol. 4, no. 1, Jan. 1921, pp. 21–27 and (discussion) pp. 28–31, 7 figs. Analysis of heating and ventilation problem for paper machine room, need for adequate ventilation to remove moisture and description of systems in use and proposed.

HELICOPTERS

Problem of. The Problem of the Helicopter. Aeronautical Jl., vol. 25, no. 121, Jan. 1921, pp. 3–19, 10 figs. Probable characteristics of first type of helicopter which will be constructed.

HYDRAULIC TURBINES

Manufacture. Machining Large Water Turbines, Fred H. Colvin. Am. Mach., vol. 53, no. 27, Dec. 30, 1920, pp. 1234–1236, 5 figs. Examples of turbine work at shop of Pelton Water Wheel Co., San Francisco.

HYDRODYNAMICS

Vortices in Liquids. Motion of Liquids (Sur le mouvement permanent des liquides), L. Lecornu. Comptes rendus des Séances de l'Académie des Sciences, vol. 171, no. 19, Nov. 8, 1920, pp. 881–885. Equations of vortex motion.

HYDROELECTRIC PLANTS

California. Forward Steps in California Hydro-Electric Designs. Eng. News-Rec., vol. 85, no. 27, Dec. 30, 1920, pp. 1260–1262, 3 figs. Unusual features include 200,000-volt transmission lines and larger units and higher reaction-turbine heads than have previously been used.

Chile. Braden Copper Company's Power System in Chile. Power, vol. 52, no. 19, Nov. 9, 1920, pp. 730–734, 8 figs. Two hydroelectric plants supply power to copper mines. One 22,500-kw. plant operated under 1550-ft. head. Other plant, 15,000 kw., operates under 440-ft. head.

Ejector Sluice Valves. The Action of Ejector Sluice Valves (Die Wirkung von Ejektorenschützen), H. Krey. Zentralblatt der Bauverwaltung, vol. 40, no. 75, Sept. 18, 1920, pp. 472–473, 2 figs. As result of observation that the tailwater from water-power plants is lowered through the waste water flowing over dam, whereby the output of turbine is increased, the idea was conceived to utilize this water for increasing the water power by use of so-called ejector sluices which by their suction act to increase head on turbine. In present article writer attempts to calculate increase of head attainable in order to ascertain feasibility and manner of plant required.

France. Hydroelectric Project for Complete Utilization of water Power in Allier Valley (Aménagement hydraulique intégral de la vallée de l'Allier). Revue générale de l'Électricité, vol. 8, no. 26, Dec. 25, 1920, pp. 907–915, 10 figs. Study for utilization of water power. From report submitted by various official committees.

The Hydroelectric Plants at Louron (Usines hydroelectriques du Louron), Marcel Waternaux, Revue générale de l'Électricité, vol. 8, no. 22, Nov. 27, 1920, pp. 765–778, 20 figs. Description of plants and details of transmission lines. Energy is transmitted at 125,000 volts.

5000-ft. Head. A 5000-Ft. Head Hydro-Electric Plant. Eng., vol. 110, no. 2869, Dec. 24, 1920, pp. 823–826, 7 figs. Installation at Fully, Switzerland. Generating station contains four sets each of 3000 hp., which run at 500 r.p.m., the Pelton wheels each having single jet which strikes wheel horizontally at its lowest point.

Lock Operation. The Influence of Lock Operation on the Hydroelectric Plants on the Canalized Neckar River (Der Einfluss der Schiffschleusungen auf die Wasserkraftanlagen an dem zu kanalisierenden Neckar.) Zentralblatt der Bauverwaltung, vol. 40, no. 77, Sept. 25, 1920, pp. 485–490, 7 figs. Gives results of locking experiments in the supply channel of the municipal electric power station in Poppen- ... the draft tube.

Niagara Falls Power Development. Switch and Control Equipment at Niagara Falls, Stephen Q. Hayes. Elec. Rev. (Chicago), vol. 78, no. 2, Jan. 8, 1921, pp. 47–53, 10 figs. Precautions taken to guard generating apparatus. Indicating devices and instruments important factors in station operation. Switchgear for main generating units housed in substation. (To be continued.)

Scotland. The Inshes Hydro-Electric Installation. Elec. Rev. (Lond.), vol. 87, no. 2248, Dec. 24, 1920, pp. 803–804, 6 figs. Details of 50-kw. hydroelectric scheme in Scotland.

I

ICE PLANTS

Motor-Driven. Motor-Driven Ice-Plants—Electrical Consumption per Ton of Ice, John E. Starr. Power, vol. 52, no. 19, Nov. 9, 1920, pp. 742–743, 1 fig. Under usual conditions of pressures, loads, temperatures and volumetric efficiency, 48.5 kw.-hr. per ton of ice is usual result.

See also ELECTRIC DRIVE, Refrigerating Plants.

INDUSTRIAL EFFICIENCY

Health. The Cult of the Sound Body, T. V. Davidson. Sci. Am. Monthly, vol. 3, no. 1, Jan. 1921, pp. 33–36, 12 figs. Apparatus employed in modern physiological laboratories to test physical development.

INDUSTRIAL MANAGEMENT

Drafting Department. The Industrial Organization of the Drafting Department (L'organisation industrielle du bureau de dessin), Danty-Lafrance. Vie Technique & Industrielle, vol. 2, no. 14, Nov. 1920, pp. 134–140, 7 figs. Suggestions in regard to adopting symbolic nomenclature, standardization of records, etc.

Employment Relations. Building Workman Morale by Advertising, Harry Botsford. Iron Age, vol. 107, No. 2, Jan. 13, 1921, pp. 131. Dodge Mfg. Co., manufacturers of pulleys and power transmission equipment, display their advertising literature on billboard to inspire workmen to make good tribute paid them in it.

Inspection. Inspection as an Aid to Planning, George S. Radford. Indus. Management, vol. 61, no. 1, Jan. 1, 1921, pp. 25–30. How central inspection regulates flow of work.

Production Systems. Assuring Continuous Production. Elec. World, vol. 77, no. 3, Jan. 15, 1921, pp. 144–146, 3 figs. Standards of inspection adopted in several large plants in connection with successful maintenance work based on long experience under industrial conditions.

Fixtures for Quantity Production of Truck Parts—II. Metal Trades, vol. 12, no. 1, Jan. 1921, pp. 5–10, 10 figs.

Increasing Production with Standard Equipment. Machy. (Lond.), vol. 17, nos. 430 and 431, Dec. 23 and 30, 1920, pp. 437–355 and 380–382, 8 figs. Comparison of output and manufacturing costs for specific drilling operation under varying conditions.

Organization for Economic Production (Organisatorische Massnahmen bei der Fertigungssparwirtschaft), E. Springorum. Betrieb, vol. 3, no. 3, Nov. 10, 1920, pp. 59–60. It is shown how, through systematic superintendence of material, saving can be effected.

The Character, Effect, Possibilities and Limitations of Industrial Specialization (Die industrielle Spezialisierung, Wesen, Wirkung, Durchfuhrungsmöglichkeiten und Grenzen), H. Döhne. Zeit. des Vereines deutscher Ingenieure, vol. 64, no. 45, Nov. 6, 1920, pp. 937–939. Review and discussion of report of investigations of Committee on Economic Production.

Purchasing Materials. Purchasing Records and System, Wilfred G. Astie. Elec. Traction, vol. 16, no. 12, Dec. 1920, pp. 941–945, 8 figs. Forms for keeping of records.

Routing Work. Handling and Routing Large Work. Machy. (N. Y.), vol. 27, no. 4, Dec. 1920, pp. 358–364, 17 figs. Methods employed by Manning, Maxwell & Moore, Inc., in Putnam Machine Works, Fitchburg, Mass., for routing of work through factory.

Time Study. See TIME STUDY

INDUSTRIAL RELATIONS

Open Shop Movement in U. S. Government Demands Open Shop, T. C. Dickson. Iron Trade Rev., vol. 67, no. 26, Dec. 23, 1920, pp. 1734–1735. Refuses to deal with trade unions in operation of arsenals, though promoting shop committee system of representation. Commanding officer describes War Department's methods in dealing with labor problems. Paper read before National Founders' Assn.

... before National Founders' Assn.

Plans. Relations Between Employers and Employed. Monthly Labor Rev., vol. 11, no. 6, Dec. 1920, pp. 94–103. Portland, Oregon, plan of preventing labor disputes, and Rochester plan of industrial democracy.

INTERCHANGEABLE MANUFACTURE

Allowances. Designations for Allowances (Passungszeichen), C. Volk. Betrieb, vol. 3, no. 3, Nov. 10, 1920, pp. 41–43, 2 figs. Various such designations are shown in a table and chart, giving reasons for designation, advantages and disadvantages. Report of German Industry Committee on Standards.

Fit Allowances. A System of Fit Allowances, Sydney B. Austin. Machy. (Lond.), vol. 17, no. 431, Dec. 30, 1920, pp. 384–386, 3 figs. Curves showing relation of allowances for fits to various diameters. Comparison of theoretical curves with Brown & Sharpe system of fit allowances and with Newall Engineering Co.'s system of fits.

INTERNAL-COMBUSTION ENGINES

Accessories. Improvements in Construction of Internal-Combustion Engines (Neuerungen auf dem Gebiet der Verbrennungskraftmaschinen). Wirtschafts-Motor, no. 11, Nov. 1920, pp. 21–22, 7 figs. Describes starting handle patented by the Austrian Daimler Motor Corp'n which can be turned only within a certain angle; a joint between spark plug and cylinder patented by Marc Birkigt, Bois Colombes, France, for purpose of introducing a simpler and more effective packing than is now in use; and a new electric starting device patented by Louis Renault, Billancourt, France, in which the electro-magnet consists of two windings, one of fine and the other of large wire between which there is a contact for shutting off the current of starting motor.

Exhaust Gas Losses. A Meter for Measuring Heat Losses in Exhaust Gas (Ein Abgasverlustmesser als Hilfsmittel für die Feuerführung), Fr. Wiedemann. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 43, no. 44, Oct. 29, 1920, pp. 335–336, 2 figs. Consists of a resistance meter so connected that it indicates difference in temperature of thermometers measuring respectively temperature of stock gases for air and combustion.

Four-Stroke vs. Two-Stroke. Four-Stroke vs. Two-Stroke System for Marine Engines (Viertakt und Zweitakt beim Schiffsmotor), Max Wilhelm Gerhards. Motorwagen, vol. 23, no. 30, Oct. 31, 1920, pp. 567–572. Critical discussion of the relative merits of both systems.

Fuels. The Proper Selection of Fuel for the Oil Engine, Allen F. Brewer. Power, vol. 52, no. 25, Dec. 21, 1920, pp. 972–974. Comparative properties of typical oils.

[See also AEROPLANE ENGINES; AUTOMOBILE ENGINES; DIESEL ENGINES; GAS ENGINES; GASOLINE ENGINES; OIL ENGINES; TRACTOR ENGINES.]

IRON

Metallography. The Practical Application of the Metallography of Iron (Die praktische Anwendung der Metallographie des Eisens), G. Berndt. Zeit. der Deutschen Gesellschaft für Mechanik u. Optik, nos. 13–14, 15–16, 17–18 and 19–20, July 15, Aug. 15, Sept. 15 and Oct. 15, 1920, pp. 73–78, 86–91, 98–103 and 109–114, 31 figs. Notes on thermal analysis for determining the relation of different portions of texture appearing in iron and other metals. Various examples are given of solution in liquid and solid state. Photomicrographs. Report from the mechanical laboratory of the C. P. Goerz Optical Works.

IRON CASTINGS

Fluid Pressure in Molds. Pressure Due to Fluid Iron in Moulds, C. Webster. Mech. World, vol. 68, no. 1772, Dec. 17, 1920, pp. 442–443, 16 figs. Influence of pressure of fluid iron in straining, bursting and lifting of molds.

IRON METALLURGY

Control of Mixtures. Chemist Controls All Iron Mixtures. Foundry, vol. 49, no. 2, Jan. 15, 1921, pp. 59–62, 5 figs. Melting department in foundry of large plant with diversified output regulated by laboratory. Inclined skip hoist charges cupola.

Elements in Iron Control Mixtures, Fletcher Collins. Foundry, vol. 49, no. 2, Jan. 15, 1921, pp. 64–65. Hardness of cast iron mainly determined by state of carbon which is controlled by other elements. Silicon tends to free carbon and sulphur to hold it in combination.

K

KEYWAYS

Depth. Computing the Depth of Keyway inG ear and Pulley Hubs, Henry R. Bowman. Am. Mach., vol. 54, no. 2, Jan. 13, 1921, p. 69. Formula.

L

LABOR

Child. Child Labor. Monthly Labor Rev., vol. 11, no. 6, Dec. 1920, pp. 126–131. Industrial instability of child workers in Connecticut.

LATHES

Zimmermann Automatic. The Zimmermann Automatic Lathe for the Rounding of Gear-Tooth Edges (Der Zimmermann-Zahnkanten-Abrund-Automat). Der praktische Maschinen-Konstrukteur, vol. 53, no. 44, Nov. 4, 1920, pp. 189–192, 10 figs. Machine for rounding off ends of gear teeth by means of an end mill, and rounding off automatically pinions up to 400 mm. diam.

LIGHTING

Direct vs. Diffused Light. Pleasing Proportions of Direct and Diffused Light from a Floor Lamp, J. R. Cravath. Trans. Illuminating Eng. Soc., vol. 15, no. 9, Dec. 30, 1920, pp. 631–644, 6 figs. Results of tests to determine pleasing proportions of direct and diffuse light from floor lamp under certain specified conditions.

Industrial. Significant Developments in Illumination During 1920, Preston S. Millar. Elec. World, vol. 77, no. 2, Jan. 8, 1921, pp. 82–85, 6 figs. Types of industrial lighting. Survey of progress in automobile headlight design.

Reflectors. The Standardization of Reflectors for Industrial Lighting. Illuminating Engr., vol. 13, no. 9, Sept. 1920, pp. 253–254, 2 figs. Photometric device for comparing efficiency of reflectors.

LIGNITE

Briquets. Lignite Bricks Pave Canada's Way to Fuel Independence, Walter Noble Burns. Coal Age, vol. 19, no. 2, Jan. 13, 1921, pp. 65–66, 1 fig. Lignite utilization board to place briquets on market. If they prove commercial success 300 new plants will be erected.

Canadian. Carbonization of Canadian Lignite, Edgar Stansfield. Jl. Indus. & Eng. Chem., vol. 13, no. 1, Jan. 1921, pp. 17–23, 4 figs. Laboratory tests by chemical staff of Fuel Testing Division of Mines Branch, Department of Mines, Ottawa.

LOCOMOTIVES

Auxiliary Tractor. Development of the Locomotive Auxiliary Tractor, J. Snowden Bell. Ry. & Locomotive Eng., vol. 34, no. 1, Jan. 1921, pp. 19–21, 5 figs. Survey of patented devices.

Axle Pressure. Axle-Pressure Variations in Locomotives Due to the Tractive Effort Exerted (Achsdruckänderungen bei Lokomotiven durch die ausgeübte Zugkraft), Paul Ritter. Annalen für Gewerbe u. Bauwesen, vol. 87, no. 6, Sept. 15, 1920, pp. 47–48, 2 figs. Examples are given showing change brought about in axle pressure distribution by tractive effort exerted; increase in many cases amounts to 15 per cent and in some cases to 25 per cent.

British. British Locomotive Progress. Railroad Herald, vol. 25, no. 1, Dec. 1920, pp. 16–18, 1 fig. Three-cylinder engine has become standard on one road. Large articulated compound engine not yet used. Superheaters increase.

Bureau of Locomotive Inspection. Report of the Bureau of Locomotive Inspection. Ry. Mech. Engr., vol. 95, no. 1, Jan. 1921, pp. 18–20, 4 figs. Application of water columns and other devices advocated; accidents increase in fiscal year 1920.

Report of Chief Inspector of Boilers, A. G. Pack. Ry. Jl., vol. 27, no. 1, Jan. 1921, pp. 17–25, 7 figs. Statistics of defects on parts and appurtenances of locomotive and tender, including boiler, together with casualties resulting from failures.

Compressed-Air. Study of the Triple-Expansion Compressed-Air Locomotive and the Utilization of Exhaust Steam in the Compression of Air at High Pressure (Etude sur les locomotives à air comprimé à triple expansion et l'utilisation de la vapeur d'échappement à la production de l'air à haute pression), M. P.-E. Leroux. Bulletin et Comptes rendus mensuels de la Société de l'Industrie minerale, vol. 19, no. 6, Nov.-Dec. 1920, pp. 249–305, 60 figs. Technical and economical study.

Cylinders. Tests of Cast Iron for Locomotive-Cylinder Parts. Am. Mach., vol. 53, no. 27, Dec. 30, 1920, pp. 1221–1222. Mechanical tests at Bureau of Standards.

Electric. See ELECTRIC LOCOMOTIVES.

Internal-Combustion. Internal Combustion Locomotives and Rail Cars of McEwan and Pratt, Ltd., George Frederick Zimmer. Eng. & Indus. Management, vol. 4, no. 27, Dec. 30, 1920, pp. 849–851, 2 figs. Locomotives used on rail tracks in factories, works, plantations, quarries, mines and also for light transitory purposes for erection of contract work. Special attention is given to reversing mechanism.

Lubrication. Lubrication of Locomotives (Lubricación de locomotoras), J. W. D. Ayre. Ingenieria internacional, vol. 5, no. 1, Jan. 1921, pp. 18–23, 25 figs. Details for economical lubrication.

Manufacture. Production Methods in Railway Locomotive Plants. Machy. (Lond.), vol. 17, no. 432, Jan. 6, 1921, pp. 405–410, 11 figs. Practice of Sir W. G. Armstrong, Whitworth & Co., Ltd., Scotswood, Newcastle-on-Tyne.

Mine. Changes in Electric Locomotives to Meet Demands for Heavier Duty, Graham Bright. Coal Age, vol. 19, no. 2, Jan. 13, 1921, pp. 51–56, 11 figs. Frames of bar steel resist damage and assist ventilation of motors. Leaf spring has advantage over helical. Thrust resisted by removable lid of boxing. Detachable rims and split gears are of questionable merit. Tandem locomotives and fan ventilation meet demand for more power.

Oil-Burning. Oil Burning Tests in the Locomotives of the Paris-Lyons-Mediterranee (Essais de chauffage au mazout effectués par la compagnie P. L. M.), M. Pouillon. Revue générale des Chemins de Fer, vol. 39, no. 1, July 1920, pp. 3–7. Burner used was of nappe type with pulverization by means of steam. Tests proved satisfactory in all respects.

Reconstruction. Increasing the Capacity of Old Locomotives, C. B. Smith. Mech. Eng., vol. 43, no. 1, Jan. 1921, pp. 12 and 16. Problems of adapting old-type locomotives to suburban and local service are discussed and items which are to be considered in any program for increasing locomotive capacity are listed. Examples of satisfactory reconstruction are cited.

Speed Capacity. The Speed Capacity of Locomotives, Cecil J. Allen. Ry. Engr., vol. 41, no. 491, Dec. 1920, pp. 489–491. Discussed more particularly in relation to diameter of driving wheels and coupling of axles.

Superheater. Determination of the Best Cylinder Diameter for Superheated Steam Locomotives (Die Bestimmung der zweckmässigsten Zylinderdurchmesser für Heissdampflokomotiven), H. Velte. Annalen für Bewerbe u. Bauwesen, vol. 87, no. 9, Nov. 1, 1920, pp. 65–68, 4 figs. Based on method described by author in same journal (vol. 87, pp. 2–7, 9–14 and 17–22), a number of superheated-steam freight-train locomotives are investigated and a method developed with which it is possible to establish cylinder diameters of such locomotives in such a way as to positively ensure operating qualities required of them.

LUBRICATING OILS

Specifications. Lubricating Oils. Air Service Information Circular, vol. 2, no. 118, Oct. 20, 1920, 7 pp., 3 figs. Specifications and method for testing.

Testing. Methods of Examination of Lubricating Oils, G. F. Robertshaw. Jl. Instn. Petroleum Technologists, vol. 6, no. 24, Oct. 1920, pp. 324–364 and (discussion), pp. 364–378, 1 fig. Methods of testing. Bibliography of lubricating oils.

LUBRICATION

Developments. Advances in the Practice of Lubrication, Henry M. Wells and James E. Southcombe. Can. Chem. & Metallurgy, vol. 5, no. 1, Jan. 1921, pp. 10–13. Experimental work connected with introduction of fatty acids in place of fatty oils. Results of trials on all types of machinery.

Oil-Circulating Systems. Preventing Emulsification in Oil-Circulating Systems, R. E. Langston. Power, vol. 52, no. 19, Nov. 9, 1920, pp. 470–741, 2 figs. Kind of oil to use in circulation systems to avoid forming emulsion.

Problems of. Some Problems of Lubrication, W. B. Hardy. Nature (Lond.), vol. 106, no. 2670, Dec. 30, 1920, pp. 569–572. Experiments to study relation of lubricating power to chemical constitution.

Research. British Lubrication-Research Report. Commerce Reports, no. 9, Jan. 12, 1921, pp. 211–213. Final report of British Department of Scientific and Industrial Research. (Abstract.)

Lubricants and Lubrication. Engr., vol. 130, no. 3390, Dec. 17, 1920, p. 605. Report of Lubricants and Lubrication Inquiry Committee appointed by Advisory Council of Department of Scientific and Industrial Research.

Lubrication. Times Eng. Supp., no. 554, Dec. 1920, p. 381. Report of Lubricants and Lubrication Inquiry Committee set up by Department of Scientific and Industrial Research.

M

MACHINE SHOPS

Layout. Accessibility, Convenience and Cleanliness Make This Machine Shop Efficient, Dever C. Ashmead. Coal Age, vol. 18, no. 26, Dec. 23, 1920, pp. 1269–127', 4 figs. Layout of machine shop near Hazleton, Pa.

MACHINE TOOLS

Automatic. The Galco Automatic Machines (Les machines automatiques "Galco"), M. Bousquet. Vie technique & industrielle, vol. 2, no. 13, Oct. 1920, pp. 38–44, 15 figs. Swedish machine for cold drawing of rivets, bolts, etc.

Axle-Machining Equipment. Axle Machining Equipment. Engr., vol. 130, no. 3386, Nov. 19, 1920, pp. 508 and 512, 6 figs. Axle facing and centering machine and axle turning lathe exhibited at machine tool exhibition at Olympia.

Belt Drive. Group vs. Individual Drive for Machine Tools, R. F. Jones. Belting, vol. 18, no. 1, Jan. 1921, pp. 59–62, 2 figs. Group offers practically all advantages of individual and in addition first cost is much lower, maintenance charges less and depreciation slower.

Developments. The Shipbuilding, Engineering and Electrical Exhibition, Kelvin Hall, Glasgow. Machy. (Lond.), vol. 17, no. 428, Dec. 9, 1920, pp. 282–285, 8 figs. Developments in machine-tool field.

Power Consumed. Influence of Shape of Chips on the Power Consumption of Machine Tools (Einfluss der Spanform auf den Kraftverbrauch von Werkzeugmaschinen), Th. Damm. Werkstattstechnik, vol. 14, no. 19, Oct. 1, 1920, pp. 507–508, 1 fig. Results of tests carried out on a planing machine, shown in table and chart.

Working Speeds. Alignment Chart for Operating Speeds (Fluchtlinientafel für Laufzeiten), Alfred Leistikow. Betrieb, vol. 3, no. 5, Dec. 10, 1920, pp. 120–123, 1 fig. Presents chart with eight scales, namely, (A) feed in mm.; (B1) and (B2) cutting speed per sec. and per min.; (C) diam. and length in cm.; (D) minutes for 1 cutting; (E) minutes for two and three cuttings; (F) diam. of workpiece in mm.; and (G) revolutions per min.

Alignment Charts for the Calculation of Working Speed of Machine Tools (Fluchtlinientafeln zur Berechnung von Laufzeiten der Werkzeugmaschinen) F. Gabriel. Betrieb, vol. 3, no. 5, Dec. 10, 1920, pp. 115–120, 8 figs. Describes lathe, shaping, and milling-machine calculators introduced by the "Stugra" Central Bur. for Graphic Tables, Waidmannslust, near Berlin, and based on alignment transformation principle.

MALLEABLE IRON

Manufacture. American Malleable Cast Iron—II. Iron Trade Rev., vol. 68, no. 3, Jan. 20, 1921, pp. 213–218, 2 figs. Developments of malleable industry in U. S.

See also CASTINGS, Malleable.

MANGANESE STEEL

Machining. Manganese Steel and Methods of Machining It, S. A. Hand. Am. Mach., vol. 54, no. 2, Jan. 13, 1921, pp. 43–45, 3 figs. Grinding is only method of machining.

MARINE BOILERS

Electric Welding. A Revolution in Marine Boiler Construction, Francis Butt-Gow. Boiler Maker, vol. 21, no. 1, Jan. 1921, pp. 1–4, 9 figs. Electric welding of Scotch marine boilers at works of R. & W. Hawthorn Leslie & Co., England.

Manufacture. Willamette's War Work, Fred H. Colvin. Am. Mach., vol. 54, no. 3, Jan. 20, 1921, pp. 105–107, 6 figs. Production manufacture of marine boilers.

MARINE ENGINES

Governors. The Ramsay Marine Governor. Practical Engr., vol. 62, no. 1764, Dec. 16, 1920, pp. 388–391, 6 figs. Anticipating valve comes automatically into action when lift of ship's stern brings propellor dangerously near surface.

[See also OIL ENGINES, Marine.]

MEASUREMENT

Optical Devices. Improvements in Measuring Tools (Neurungen an Messwerkzeugen), Max Kurrein. Werkstattstechnik, vol. 14, nos. 19 and 20, Oct. 1 and 15, 1920, pp. 513–517 and 538–544, 46 figs. Details of various new measuring-tool constructions by the Fried. Krupp Corp., and of accurate measuring apparatus by firm of Carl Zeiss, particularly optical measuring devices.

METALS

Fatigue. The Relation of Recoverance to the Fatigue of Metals, Robert G. Guthrie. Jl. Soc. Automotive Engrs., vol. 8, no. 1, Jan. 1921, pp. 65–68, 2 figs. Description of modulimeter, an apparatus for measuring recoverance. Recoverance is capacity of material to return immediately energy that has been imparted to it by any external force.

METEOROLOGY

Atmospheric Pressure-Temperature Relations. The Relationship Between Pressure and Temperature at the Same Level in the Free Atmosphere, E. H. Chapman. Proc. Royal Soc., vol. 98, series A, no. A691, Dec. 3, 1920, pp. 235–248, 1 fig. Correlation coefficients between pressure and temperature at same level in free atmosphere.

METRIC SYSTEM

U. S. Senate Bill. A New Metric System Bill. Iron Age, vol. 106, no. 26, Dec. 23, 1920, pp. 1677. Principal features of bill introduced into Senate on Dec. 21, 1920, to establish Metric System in United States.

The Metric System Bill Introduced in the Senate. Am. Mach., vol. 53, no. 27, Dec. 30, 1920, pp. 1248–1249. Text of bill providing for compulsory use of Metric System in United States recently introduced in Senate.

MILLING

Continuous. Continuous Milling of Pump Bodies. Am. Mach., vol. 54, no. 3, Jan. 20, 1921, pp. 108–109, 5 figs. Table revolves to feed work, and castings are replaced while machine is cutting.

MILLING MACHINES

Cutter Selection. Proposals for New Factory Instruction Sheets (Entwürfe neuer Betriebsblätter). Betrieb, vol. 3, no. 4, Nov. 25, 1920, pp. 31–32. Proposal of the Committee for Economic Production (AWF) for a new instruction sheet containing directions for the selection and manipulation of milling cutters.

Horizontal. Horizontal Milling Machine. Eng., vol. 110, no. 2869, Dec. 24, 1920, pp. 834–836, 8 figs. Single pulley type machine constructed by Alfred Herbert, Coventry, England. Pulley is mounted on ball bearings, which are fitted to fixed sleeve attached to body of machine.

Locomotive-Frame. Milling Machine for Locomotive Frames, Hartwig Orenstein. Eng. Progress, vol. 1, no. 12, Dec. 1920, pp. 365–366. Three-column milling machine for milling frames having 11 meters in length, used at locomotive works in Berlin.

Multiple. Large Multiple Milling Machines (Grosse Mehrfach-Fräsmaschine), Der praktische Maschinen-Konstrukteur, vol. 53, no. 38, Sept. 25,

other large Diesel-engine parts. Operates with three double spindles, each of which independently is driven by a special motor, resulting in a great simplification of driving parts.

MINE HAULAGE

Colliery Plant. Electric Haulage and Ventilating Plant at the Easington Colliery. Eng., vol. 110, no. 2868, Dec. 17, 1920, pp. 804–806 and 808, 10 figs. Various electric haulages comprise two large main-and-tail haulages of 600 hp. and 450 hp., respectively, and three endless haulages, two of which are of 160 hp. and third of 85 hp.

Continuous. Continuous Hoisting from Great Depths (Stetige Förderung aus grossen Teufen), A. Winkel. Fördertechnik u. Frachtverkehr, vol. 13, nos. 19, 20 and 21, Sept. 17, Oct. 1 and 15, 1920, pp. 173–176, 184–188 and 195–198, 12 figs. Notes on the development of continuous hoisting systems for deep shafts and determination of the economically and technically most advantageous type. Comparison of electric and steam installations of same capacity.

MOMENT OF INERTIA

Unsymmetrical Sections. Calculating the Strength of Unsymmetrical Sections, G. S. Chiles and R. G. Kelley. Machy. (N. Y.), vol. 27, no. 4, Dec. 1920, pp. 345–348. Methods of determining moment of inertia, together with formulas for obtaining section modulus and radius of gyration.

MOTOR BOATS

Engines. Commercial Motor Boats and the Diesel Engine, G. D. Cavison. Jl. Soc. Automotive Engrs., vol. 8, no. 1, Jan. 1921, pp. 46–50, 7 figs. Chart showing comparative operating costs of Diesel, hot-bulb and gas engines.

MOTOR PLOWS

Wheel Design. Plowing by Machinery (Le problème de l'adhérence), F. Mirès. Vie technique & industrielle, vol. 2, no. 15, Dec. 1920, pp. 207–211, 21 figs. Types of wheels required to develop sufficient adherence between wheels and soil. (To be continued.)

MOTOR-TRUCK TRANSPORTATION

Germany. Development of Public Motor Transport in Germany, Benno R. Dierfeld. Automotive Industries, vol. 43, no. 26, Dec. 23, 1920, pp. 1251–1254, 3 figs. Vehicles are operated in large fleets by trained staffs, service being controlled by motor transportation companies owned by local governments. Post Office Department operates passenger vehicles.

MOTOR TRUCKS

Axles. A New Dual Reduction Truck Axle, P. M. Heldt. Automotive Industries, vol. 44, no. 1, Jan. 6, 1921, pp. 10–13, 6 figs. Dual reduction axle with drop-forged housing of double banjo type.

Body Design. Engineering Features of New British Trucks at Olympia, M. W. Bourdon. Automotive Industries, vol. 43, no. 25, Dec. 16, 1920, pp. 1207–1212, 20 figs. Careful attention to details heretofore neglected and many refinements in design feature new models. Bristol 3 to 4-ton has electric lights, new transmission and 16-in. single-plate clutch. Halley uses 6-cylinder engine, shaft brake at rear of worm and novel steering connections. Austin has only unit powerplant. Single plate clutch, propeller shaft brakes, overhead worms, plain bearing rear axles and steel wheels, generally used.

Design. The Trend of Motor Truck Design for 1921, Victor W. Page. Sci. Am., vol. 124, no. 2, Jan. 8, 1921, pp. 30–31 and 38–40, 12 figs. Brief survey of features displayed by 682 American models.

German-Built. Motor Lorries, Rudolf Urtel. Eng. Progress, vol. 1, no. 12, Dec. 1920, pp. 360–363, 5 figs. Survey of recent developments in Germany and record of standardization work.

Quantity Production. Fixtures for Quantity Production of Truck Parts—I. Metal Trades, vol. 11, no. 12, Dec. 1920, pp. 489–493, 8 figs. Fixtures used by Fageol Motors Co. (To be continued.)

Specifications. Complete Mechanical Specifications of all Makes of 1921 Gasoline Motor Trucks. Commercial Vehicle, vol. 23, no. 11, Jan. 1, 1921, pp. 356–378. Details of 527 gasoline, 22 electric and one steam motor truck chassis as produced by 227 American truck manufacturers.

Internal-Combustion Truck Specifications. Power Wagon, no. 194, Jan. 1921, pp. 42–59. List of specifications of 570 makes.

Wheels. Machining Motor Truck Wheels. Machy. (N. Y.), vol. 27, no. 4, Dec. 1920, pp. 349–355, 15 figs. Also Machy. (Lond.), vol. 17, no. 432, Jan. 6, 1921, pp. 411–417, 15 figs. Practice of Clark Equipment Co., Buchanan, Mich., in production of steel truck wheels.

N

NAVIGATION

Hydrophone. U. S. Navy MV Type of Hydrophone as an Aid and Safeguard to Navigation, H. C. Hayes. Proc. Am. Philosophical Soc., vol. 59, no. 5, 1920, pp. 371–404, 12 figs. Uses of apparatus developed during war for determining direction of submerged submarine.

NICKEL

Properties. Physical Properties of Nickel, Paul D. Merica. Chem. & Metallurgical Eng., vol. thermal, electrical and optical properties of pure nickel.

NICKEL STEEL

Instability. Cause of Instability of Nickel Steels, and Its Removal (Cause de l'instabilité des aciers au nickel; son élimination), Ch.-Ed. Guillaume. Comptes rendus des Séances de l'Académie des Sciences, vol. 171, no. 22, Nov. 29, 1920, pp. 1039–1041. Instability is due to slow transformation of cementite. Addition of third metal having greater affinity for carbon than iron prevents formation of cementite and thus increases stability of alloy.

NICKEL-CHROMIUM STEEL

Uses. Applications of Alloy Steels in Automotive Industries, H. J. French. Automotive Manufacturer, vol. 42, no. 9, Dec. 1920, pp. 24–28, 9 figs. Nickel-chromium steels and their advantageous properties, especially for transmission and other gears, aeroplane and other crankshafts, and other highly important parts.

O

OIL ENGINES

Manufacture. Prospects and Problems in Construction of Oil Engines (Aussichten und Aufgaben des Oelmaschinenbaues), Paul Rieppel. Zeit. des Vereines deutscher Ingenieure, vol. 64, nos. 49 and 50, Dec. 4 and 11, 1920, pp. 1021–1026 and 1051–1055, 10 figs. Prospective development of the injection-type and carburetor engines; the injection-type engine for marine purposes; combustion phenomenon and control of heat, the compressorless engine. Special technical problems: Wheel gearing and reversing; construction materials and lubrication; the injection-type engine as locomotive; starting and power transmission; hydraulic drives; carburetor engines for agricultural work and in factories, for automobiles and aeroplanes. Carburation inside and outside of cylinder.

Marine. Modern Marine Oil Engines. Shipbuilding & Shipping Rec., Special Number, Jan. 5, 1921, pp. 58–60, 5 figs. Survey of different types of internal-combustion engine available for propulsion of merchant ships.

Solid-Injection. The Solid-Injection Oil Engine, Edgar J. Kates. Power, vol. 52, no. 26, Dec. 28, 1920, pp. 1008–1010, 3 figs. Fuel consumption test on 200-hp. solid injection oil engine.

OIL FUEL

Coal and Gas vs. Fuel Oil. Power Plant Eng., vol. 25, no. 1, Jan. 1, 1921, pp. 51–55, 9 figs. Chart for determining relative costs of oil, gas and coal for equal economy.

Specifications. Specifications for Oil Fuel (Au sujet des conditions de recette des combustible liquides), Pierre Appell. Chaleur & Industrie, no. 8, Nov.-Dec. 1920, pp. 490–495. Specifications of French and British navies and of U. S. Bureau of Mines.

Uses. Uses of Oil Fuel (Les emplois de mazout), Norbert Lallie. Vie technique et industrielle, vol. 2, nos. 13, 14 and 15, Oct., Nov. and Dec., 1920, pp. 25–32, 121–125 and 217–223, 42 figs. Oct.: Industrial uses, and methods of combustion; Nov. and Dec.: Types of burners.

OILS

Slushing. Slushing Oils, Percy H. Walker and Lawrence L. Steele. Technologic Papers, Bur. of Standards, no. 176, Oct. 14, 1920, 23 pp. Desired properties of slushing oils. Laboratory tests on slushing compounds. Proposes specifications for slushing greases suitable for protection of exposed bright metal.

OPEN-HEARTH FURNACES

Manganese Utilization. The Utilization of Manganese in Basic Open-Hearth Furnaces (Beiträge zur Frage der Manganausnutzung im basischen Martinofen), Erich Killing. Stahl u. Eisen, vol. 40, no. 46, Nov. 18, 1920, pp. 1545–1547. States that utilization can be increased (1) if meltings are tapped from slag at moment of greatest reduction of manganese; (2) if manganese charge is not measured too high (1.6 to 1.8 per cent); (3) if the bases are admitted in such quantities that there is neither excess nor deficiency in proportion to absorption capacity of slag; (4) by as low a charge of lime-binding elements as possible; (5) by as high temperature as possible; and (6) admission of manganese in metallic form.

OXY-ACETYLENE CUTTING

Steel Plate. Cutting Steel Plate with a Torch. Gas Age, vol. 47, no. 1, Jan. 10, 1921, pp. 9–10, 2 figs. Machines for operating oxy-acetylene-cutting torch adopted to irregular surfaces and with automatic feed.

Torch Tips. Drilling Davis-Bournonville Cutting Torch Tips. Autogenous Welding, Jan. 1921, pp. 3–8, 14 figs. Description and illustration of drilling operation.

OXY-ACETYLENE WELDING

Efficiency of. Efficiency of Oxy-Acetylene Welding, Benjamin Heyman. Welding Engr., vol. 5, no. 12, Dec. 1920, pp. 29–32, 2 figs. Results of tests. Welding efficiency was calculated as ratio of ultimate strength of welded material in pounds per square inch and ultimate strength of unwelded material in pounds per square inch. Efficiencies thus computed varied from 77.2 to 90.5 per cent.

PEAT

Briquets. Manufacture of Peat Briquets in Sweden (Möjlighet för torvbrikettfabrikation i Sverige), Alf. Larson. Teknisk Tidskrift (Veckoupplagan), vol. 50, no. 42, Oct. 16, 1920, pp. 461–471, 12 figs. Made from deposits containing 50 per cent water.

Pulverized. The Utilization of Pulverized Peat, C. F. Herington. Power Plant Eng., vol. 25, no. 1, Jan. 1, 1921, pp. 60–62, 2 figs. Experience of plants in Minneapolis, Minn.

PENDULUM

Complex Motion. Study of Complex Pendular Systems (Études sur les systèmes pendulaires complexes), Luc Denis. Vie technique & industrielle, vol. 2, no. 15, Dec. 1920, pp. 235–236, 4 figs. Pendulum mounted on mass possessed of alternating rotary motion. (To be continued.)

PETROLEUM

Products of, Transporting. Hazards of Handling and Transporting Volatile Petroleum Products, C. P. Bowie. Reports of Investigations, Bur. of Mines, Dept. of Interior, serial no. 2195, Dec. 1920, 2 pp. Experiments showed that highly explosive mixtures of hydrocarbon vapors and air are produced when mixture contains 1.4 to 6 per cent hydrocarbon vapor and dangerous flashes may be produced with mixtures containing less or more than these proportions.

Refining. Petroleum Refining Process and Problems, H. H. Hill. Jl. Soc. Automotive Engrs., vol. 8, no. 1, Jan. 1921, pp. 51–53. Common types of refining plants.

Sulphur in. Sulphur in Petroleum Oils, C. E. Waters. Technologic Papers Bur. of Standards, no. 177, Oct. 20, 1920, 26 pp., 1 fig. Theories concerning origin of sulphur and sulphur compounds which are found in crude petroleum. Tests for detection of sulphur are described and copper test is shown to be of great delicacy.

PIG IRON

Synthetic. Furnace Earns Cost in Two Months, Herschell L. Hatt. Foundry, vol. 49, no. 1, Jan. 1, 1921, pp. 30–32, 1 fig. Experience with home-made electric furnace operated for producing synthetic pig iron from steel scrap.

Makes Pig Iron in Novel Furnaces, Herschell L. Hatt. Iron Trade Rev., vol. 68, no. 2, Jan. 13, 1921, pp. 149–151, 1 fig. Home-made electric furnace of simple construction operated for producing synthetic pig iron from steel scrap.

PIPE, CAST IRON

Founding. Cast Iron Pipe Founding at Fort William Plant, P. R. Hurley. Can. Foundryman, vol. 12, no. 1, Jan. 1921, pp. 17–19, 4 figs. Method and equipment of manufacturing cast-iron water and gas pipe.

How Soil Pipe Castings Are Made, Pat Dwyer. Foundry, vol. 49, no. 2, Jan. 15, 1921, pp. 43–47 and 50, 7 figs. Standardized manufacturing practice at plant of Somerville Iron Works, Somerville, N. J.

PIPE LINES

Calculation. The Scientific Calculation of Pipe Lines (Une méthode scientifique pour le calcul des pipe-lines). Vie technique & industrielle, vol. 2, no. 15, Dec. 1920, pp. 229–233, 4 figs. Equations deduced from theory of flow of fluids on solids.

Valves. Effect of Small Gate or Valve in Larger Pipe Line, T. E. Lally. New England Water Works Assn., vol. 34, no. 4, Dec. 1920, pp. 302–311, 4 figs. Tests to determine loss of pressure.

PISTONS

Aluminum Alloys. Aluminum Alloy Pistons, Ernest V. Pannell. Metal Industry (N. Y.), vol. 19, no. 1, Jan. 1921, pp. 15–17, 8 figs. Advantages of aluminum, alloys in use, their treatment and design, and manufacture of pistons for gasoline motors.

PLANERS

Electrically Driven. Electrically Driven Planing Machine. Engr., vol. 130, no. 3390, Dec. 17, 1920, p. 619. Machine has stroke of 30 ft. and can accommodate work up to 12 ft. in width and 8 ft. in height. Including electrical equipment machine weighs about 100 tons. Driving motor is of 70 b.hp.

Practice in Machine-Tool Plants. Production Planing in Machine Tool Plants, Edward K. Hammond. Machy. (N. Y.), vol. 27, no. 5, Jan. 1921, pp. 409–419, 15 figs. Planer practice in number of plants building milling machines.

Safety Devices. Safety Arrangements for Plate-Edge Planing Machines (Sicherheitsvorrichtungen für Blechkantenhobelmaschinen), Hugo Becker. Zeit des Vereines deutscher Ingenieure, vol. 64, no. 49, Dec. 4, 1920, pp. 1033–1037, 8 figs. Different electric drives for plate-edge planing machines with right-angled beds; safety devices for preventing the tables from colliding at the junction of beds.

PLATES

Stresses in. The Bending Stress of Plates Under Concentrated Loads (Die Biegungsbeanspruchung von Platten durch Einzelkräfte), A. Nádai. Schweizerische Bauzeitung, vol. 76, no. 23, Dec. 4, 1920, pp. 257–260. Stress is determined by author in and near the pressure surface of a thick circular plate bent by a single force.

POWER GENERATION

Development in 1920. Review of the Year. Power, vol. 53, no. 1, Jan. 4, 1921, pp. 2–21. Tendencies in design and practice in power plant field, and economic problems that must be met. Adoption and promulgation of A.S.M.E. boiler code. Studies of steam engine, uniflow engine and high-speed turbo-blowers. Progress in accident prevention.

POWER PLANTS

Development. Engineering Developments of 1920–21. Elec. World, vol. 77, no. 1, Jan. 1, 1921, pp. 17–38, 35 figs. Important developments are classified under (1) generation and protection; (2) transmission and distribution; (3) science and research, and (4) lighting and industrial. Recent tendencies and practices as revealed by prominent installations carried out in 1920 are studied for each one of these divisions.

POWER STATIONS

Design. Unit Idea in Power Station Design, Louis R. Lee. Elec. Ry. Jl., vol. 57, no. 2, Jan. 8, 1921, pp. 73–76, 1 fig. Application of unit principle to generating plants as a whole.

POWER TEST CODES

Reciprocating Steam Engines. See STEAM ENGINES, A.S.M.E. Test Code.

POWER TRANSMISSION

Pneumatic. Essential Properties of Pneumatic Transmission in a Closed Cycle (Propriétés essentielles des transmission pneumatiques en cycle fermé), Jacques de Lassus. Comptes rendus des Séances de l'Académie des Sciences, vol. 171, no. 21, Nov. 22, 1920, pp. 992–995. Laws governing polytropic changes in cycle proposed in Comptes rendus, Nov. 8, pp. 899–901.

Power Transmission by an Invariable Mass of Gas in a Closed Space (Sur une transmission d'énergie méchanique utilisant unemassei nvariable de gaz en circuit fermé), Jacques de Lassus. Comptes rendus des Séances de l'Académie des Sciences, vol. 171, no. 19, Nov. 8, 1920, pp. 899–901. Adiabatic compression in a closed space.

PRESSES

20-Ton. Power Press with Pressure Range to 20 Tons. Iron Age, vol. 107, no. 2, Jan. 13, 1921, p. 140, 1 fig. Pressure exerted upon work ranges from few pounds to 20 tons and is applied by operator on foot pedal.

PRESSWORK

Electric Motor Plant. Press Work in an Electric Motor Plant—II. Machy. (N. Y.), vol. 27, no. 4, Dec. 1920, pp. 340–344, 11 figs. Methods used in Power Press Department of General Electric Co., Lynn, Mass.

PROFIT SHARING

England. Teaching Workers to Think "Production," Cecil Chisholm. Factory, vol. 26, no. 1, Jan. 1, 1921, pp. 40–42. Experience in English works with profit-sharing systems.

PULVERIZED COAL

Advantages. Pulverized Coal. Power Plant Eng., vol. 25, no. 1, Jan. 1, 1921, pp. 56–60, 9 figs. Graph showing comparative heat values for various fuels.

[See also STEEL CASTINGS, Annealing.]

PUMPS, CENTRIFUGAL

Induction Motors for. Variables Speed Induction Motors for Centrifugal Pumps. Eng. News-Rec., vol. 85, no. 24, Dec. 9, 1920, pp. 1126–1127, 3 figs. Comparison of overall efficiencies for centrifugal unit, based on tests on motor-driven three-stage pump run at normal speed throttled or variable speeds unthrottled.

Turbine. New Contributions to the Theory of Side Thrust, Side-Thrust Equalizing Devices and Clearance Losses in Turbine Pumps (Neue Beiträge zur Theorie des Achsschubes, der Achsschubausgleichsvorrichtungen und Spaltverluste in Turbinenpumpen), L. W. Weil. Zeit. für das gesamte Turbinenwesen, vol. 17, nos. 25, 26, 28, 30 and 31, Sept. 10, 20, Oct. 10, 30 and Nov. 10, 1920, pp. 289–294, 301–307, 331–335, 356–358 and 369–372, 28 figs. Describes theoretically developed, practical and useful methods for calculation of side-thrust forces in turbine pumps and arrangements for combating them.

R

RAILS

Failure. Rail Failure Statistics for 1919, M. H. Wickhorst. Bul. Am. Ry. Eng. Assn., vol. 22, no. 229, Sept. 1920, pp. 47–87. Statistics of rail failure collected for year ending Oct. 21, 1919, furnished by railroads of United States and Canada, in response to circular sent out by American Railroad Association.

Flat-Bottom vs. Bull-Head. The Case of the Bull-Head Rail. Ry. Gaz., vol. 33, no. 23, Dec. 3, 1920, pp. 736–737. Comparison of relative advantages of flat-bottom and bull-head rails for railway track purposes.

RAILWAY CONSTRUCTION

Economics. Reeders for Railroads, Charles A. Morse. Mech. Eng., vol. 43, no. 1, Jan. 1921, pp. 19–20. Economical factors involved in construction of branch lines.

RAILWAY ELECTRIFICATION

Canada. Electrical Operation on the Canadian National. Ry. Elec. Engr., vol. 12, no. 1, Jan. 1921, pp. 25–29, 9 figs. Modification of original plan as result of amalgamation of Canadian Northern with Government railways.

Chicago. Chicago Electrification and Elevation C., M. & St. P. Ry. Eng. News-Rec., vol. 85, no. 26, Dec. 23, 1920, pp. 1226–1230, 9 figs. Third-rail passenger and trolley freight service on Evanston suburban line. Concrete walls and trestle. Precast and poured bridge decks.

European Developments. Status of Heavy Traction Abroad. Elec. Ry. Jl., vol. 57, no. 1, Jan. 1, 1921, pp. 31–36. Survey of practice in Great Britain colonies and in Continental Europe.

France. Partial Electrification of the French Railways (Electrification partielle des Chemins de fer français), A. Tretél. Électricien, vol. 36, no. 1265, Dec. 1, 1920, pp. 505–514. Progress in carrying out projects for electrification of three of principal French railways.

India. The Electrification of Indian Railways. Engr., vol. 130, nos. 3387–3388, Nov. 26–Dec. 3, 1920, pp. 530–531, 3 figs, 550–551, 4 figs. Comparative performance of electric and steam locomotives of Indian Northwestern Railway.

Operating Results from. The Electrification of Steam Railroads. Ry. Age, vol. 70, no. 1, Jan. 7, 1921, pp. 101–106, 8 figs. Brief survey of operating results on Norfolk & Western and C. M. & St. P.

Tunnels. New Catenary Construction for the Hoosac Tunnel. Ry. Elec. Engr., vol. 12, no. 1, Jan. 1921, pp. 17–20, 6 figs. Tunnel is $4^3/_4$ miles in length, being longest in U. S. Renewal of overhead equipment under traffic.

St. Clair Tunnel Operation Most Successful, R. L. Herman. Ry. Elec. Engr., vol. 12, no. 1, Jan. 1921, pp. 21–24, 6 figs. Grand trunk electrical installation. Tunnel is single-track tube 6032 ft. in length with approaches totalling 5603 ft.

Sweden. The Electrification of the Swedish State Railroads (Die Elektrisierung der schwedischen Staatsbahnen), Axel F. Enström, Emil Alm and Carl A. Rossander. Elektrotechnische Zeit., vol. 41, nos. 45 and 46, Nov. 11 and 18, 1920, pp. 893–896 and 913–916. Expert testimony of a commission appointed by the Royal Swedish State Railroad Administration setting forth relative merits of direct current and single-phase alternating current. For the section Gothenburg-Stockholm preference is given to the single-phase alternating current, and it is recommended that motive power be generated in part directly in power station and in part through conversion from three-phase current at one or a few points.

Switzerland. Electrification of the Sion-Lausanne Lines of the Swiss Federal Railways (Electrification de las ligne Sion-Lausanne des C F F). Bulletin Technique de la suisse romande, vol. 46, no. 24, Nov. 27, 1920, pp. 277–278. Details of project.

The Electrification of the Swiss Railways (L'électrification des chemins de fer Rhétiques), H. Lang. Bulletin technique de la Suisse romande, vol. 46, no. 25, Dec. 11, 1920, pp. 289–294, 9 figs. Single-phase system at 10,000-volts and $16^2/_3$ periods per second has been decided upon.

RAILWAY OPERATION

Train Control. The Marvel of Train Control, Robert G. Skerrett. Sci. Am. Monthly, vol. 3, no. 1, Jan. 1921, pp. 63–65, 4 figs. System for automatic action of air and steam hose of railway cars.

RAILWAY SIGNALING

Block System. Absolute Block-System with Closed Sections Worked by Means of the Telephone on the Belgian State Railways, L. Weissenbruch and J. Verdeyen. Bul. Int. Ry. Assn., vol. 2, no. 12, Dec. 1920, pp. 878–888. Records of operation.

Wireless Waves. Repetition of Track Signals on Board the Locomotive (Étude sur la répétition des signaux de voie à bord des locomotives), J. Bethenod. Radioélectricité, vol. 1, no. 6, Nov. 1920, pp. 292–297, 5 figs. Survey of applications of principles of wireless telegraphy to the repetition of danger and other signals on the cab of locomotive. Comparative study of schemes developed in France with those devised in United States. (To be continued.)

RAPID TRANSIT

New York City. Functions of Rapid Transit Lines in Cities, Henry M. Brinckerhoff. Eng. News-Rec., vol. 85, no. 26, Dec. 23, 1920, pp. 1235–1239, 1 fig. Capabilities of subways, elevated railways and surface lines compared from statistical records of New York City.

REFRIGERATING MACHINES

Carbon-Dioxide. The Escher Wyss & Co. Carbon-Dioxide Ice and Refrigerating Machine (Kohlensäure-Eis- und Kühlmaschine System Escher Wyss & Co.). Zeit. für Sauerstoff- u. Stickstoff-Industrie, vol. 12, no. 19–20, Oct. 1920, pp. 77–80, 3 figs. Based on evaporation of CO_2 and its condensation through compression and cooling. Advantages are said to be that machine consists of only three parts. Refrigerator, compressor and condenser, and no distillation or rectifying apparatus are required; the CO_2 is chemically inactive and, therefore, does not affect any of machine parts or packing material; purity of cooling water remains unchanged. Other advantages are durability, easy manipulation, low cost, minimum depreciation, lack of danger, etc.

REFRIGERATING PLANTS

Fish Freezers. St. Pierre Fish Freezer. Refrig. World, vol. 56, no. 1, Jan. 1921, pp. 11–16, 9 figs. Fish freezing and storing plant built for French Government on Island of St. Pierre. Machinery equipment and storage facilities are designed to take care of freezing of 200,000 bbls. of fish in 24 hr. and storing of 6,000,000 lb. of frozen fish, boxed ready for shipment.

Gas Power for. Gas Power for Refrigerating Plants, Geo. H. Trout. Ice & Refrigeration, vol. 60, no. 1, Jan. 1921, pp. 9–10. Cost of operation. Advantages of gas power.

Packing Plants. New Armour Plant at Kansas City. Power, vol. 52, no. 25, Dec. 21, 1920, pp. 966–969, 5 figs. Horizontal ammonia compressor of 500-ton capacity and generating units with mixed-pressure turbines of extraction type.

Safety Regulations. Safety Regulations for Refrigerating Plants, G. H. Crawford. Power, vol. 53, no. 1, Jan. 4, 1921, pp. 28–30, 7 figs. Study of regulations of various cities and states.

REFRIGERATION

Fish. Fish Research Committee. Interim Report on Its Investigations. Cold Storage, vol. 23, no. 273, Dec. 16, 1920, pp. 310–312, 1 fig. Suggested model low-temperature brine-freezing fish tank.

Standard Ton. Standard Ton of Refrigeration, F. E. Matthews. Refrig. World, vol. 56, no. 1, Jan. 1921, pp. 16–17. It has been defined by adoption of recommendations of special committee by Am. Soc. Refrigerating Engrs. at 288,000 B.t.u.

Standard Unit of Refrigeration, F. E. Matthews. Ice & Refrigeration, vol. 60, no. 1, Jan. 1921, pp. 49–50. Unit of 288,000 B.t.u. has been officially adopted by Am. Soc. Refrigerating Engrs.

RESEARCH

Developments in. 1920: A Retrospect. Chem. Age (Lond.), vol. 4, no. 81, Jan. 1, 1921, pp. 4–6. Developments in research, industry and invention.

Engineering Foundation. Engineering Foundation: Its Work and Needs, Alfred D. Flinn. Min & Sci. Press, vol. 122, no. 3, Jan. 15, 1921, pp. 86–87. Advisability of establishment by Engineering Foundation of Engineering Research Institute and Laboratory.

Industrial Associations. Industrial Research Associations—IV, Arnold Frobisher. Nature (Lond.), vol. 106, no. 2666, Dec. 2, 1920, pp. 443–446. British Research Association for woolen and worsted industries.

Industrial Research Associations—V, S. G. S. Panisset. Nature (Lond.), vol. 106, no. 2667, Dec. 9, 1920, pp. 475–476. British Portland Cement Research Association.

Industrial Research Associations—VII, H. S. Rowell. Nature (Lond.), vol. 106, no. 2669, Dec. 23, 1920, pp. 538–540. Research Association of British motor and allied manufacturers.

Lumber Industry. Research and Boards, Ovid M. Butler. Sci. Am. Monthly, vol. 3, no. 1, Jan. 1921, pp. 59–62, 6 figs. Need of establishing laboratories to study problems of lumber industry.

Machinery. Complete Laboratory for Research in Machinery. Iron Trade Rev., vol. 68, no. 2, Jan. 13, 1921, pp. 152–153, 4 figs. Research laboratory of National Lamp Works of General Electric Co., Cleveland installed to test and to study further development of machines used in manufacture of lamps.

Paper. Progress of U. S. Paper Laboratory in 1920. Paper, vol. 27, no. 18, Jan. 5, 1921, pp. 14–16. Important work has been done on paper-testing machines, paper substitutes, determination of sizing, quality of paper, fibre studies, etc.

RIVETS

Heating by Electricity. Heating Rivets by Electricity, J. R. Bower. Jl. Engrs. Club of Phila., vol. 38–1, no. 193, Jan. 1921, pp. 1–7, 14 figs. Principle of operation and details of construction of electric rivet heater. Comparison of heating rivets by electricity with other methods of heating.

Standards. Report of the German Industry Committee on Standards (N D I) (Mitteilungen des Normenausschusses der Deutschen Industrie). Betrieb, vol. 3, no. 5, Dec. 10, 1920, pp. 69–81, 14 figs. Proposals of the Board of Directors for round-head rivets for boiler and steel construction, symbols for rivets and screws in iron structures; countersunk-head rivets, etc. Proposed standards for concrete boundary and milestones; drain-pipe laterals; sheet-metal rivets; rules of the Committee for Units and Formular Values (AEF).

ROLLING MILLS

Electrically Driven. Electric Blooming Mill in Delaware. Iron Age, vol. 106, no. 27, Dec. 30, 1920, pp. 1733, 1 fig. Plant of Penn Seaboard Steel Corp. Rolling capacity consists of 34-in. two-high reversing blooming mill.

Operation. Practical Pointers on Rolling Mill Operation, W. S. Standiford. Can. Machy., vol. 24, no. 26, Dec. 23, 1920, pp. 555–558, 2 figs. Comparison of English and American methods of rolling

S

SAFETY

Compressed-Air Work. Revised Rules on Compressed-Air Work in New York. Eng. News-Rec., vol. 85, no. 26, Dec. 23, 1920, p. 1225. Conference of engineers, contractors, workmen and state departments adopts measures for safety of men and work.

Industrial. Securing Safety Through Competition. Iron Age, vol. 106, no. 26, Dec. 23, 1920, p. 1679, 1 fig. Plan of Dodge Mfg. Co. consists in dis-

The Best Production Methods Are the Most Economical

There is only one *best* method in turret lathe practice. Our Engineers are constantly studying and experimenting to reach that best method and keep our turret lathes up to their high standard.

The results of their study and experimenting are yours to apply to your production problems. Just write us and we'll send one of our engineers to consult with you. He may be able to save you considerable money by suggesting a tool or two or perhaps by re-arranging the tools you have. This is part of our service to you.

Turret Lathes from 4½" x 44"—21" Swing to ⅝" x 4"—10" Swing.

A. W. & S. No. 3-A finishes one of these Air Brake Pump Pistons of cold rolled stock every 20 minutes in an eastern railroad shop. This is a difficult railroad job.

ENGINEERING INDEX (Continued)

tributing small cash prizes to workers and arousing competition in departments.

Standards. Safety Standards of the Industrial Board. Commonwealth of Pennsylvania. Dept of Labor & Industry, vol. 1, no. 4, 9 pp. Railings, toe boards, platforms and runways.

SAND BLAST

Apparatus. Sand-Blasting, C. W. Starker. Machy. (N. Y.), vol. 27, no. 5, Jan. 1921, pp. 458–462, 11 figs. Types of apparatus, abrasives, nozzles, air pressures, dust exhausting, etc.

SCIENTIFIC INSTRUMENTS

Manufacture. Operations in the Manufacture of Scientific and Optical Instruments—I. Machy. (Lond.), vol. 17, no. 431, Dec. 30, 1920, pp. 389–395, 13 figs. Works of T. Cooke & Sons, York, England.

SCIENTIFIC MANAGEMENT

See INDUSTRIAL MANAGEMENT.

SCRAP

Crushing Metal Chips. The Crushing of Iron, Steel and Metal Chips (Zerkleinerung der Eisen-, Stahl- und Metallspäne), R. Philipp. Betrieb, vol. 3, no. 3, Nov. 10, 1920, pp. 67–72, 20 figs. Account of a number of tests carried out by different concerns, and description of special machine said to operate on what resembles the American Hartness process, differing from this only in the forced travel of the chips. Its useful possibilities are pointed out.

SCREW MACHINES

Circular Forming Tools. Design of Circular Forming Tools, Earl H. Smiley and J. H. Davis. Machy. (N. Y.), vol. 27, no. 4, Dec. 1920, pp. 366–369, 6 figs. Calculations for designing circular forming tools having top rake.

SCREW THREADS

Milling, Side-Cutting of Hobs in. Side-Cutting of Thread-Milling Hobs, Earle Buckingham. Mech. Eng., vol. 43, no. 1, Jan. 1921, pp. 9–11 and 62, 5 figs. Mathematical study of side-cutting action of hob. Corrections in form of thread-milling hobs to produce threads sufficiently correct as to form for all practical purposes are pointed out.

SCREWS

Manufacture. The Economical Manufacture of Rolled and Cut Screws (Die wirtschaftliche Herstellung von blanken und blank bearbeiteten Schrauben), Curt Güssow. Betrieb, vol. 3, no. 4, Nov. 25, 1920, pp. 91–92, 3 figs. States that economic production of such screws and nuts is dependent upon number of pieces and resulting loss of material. Explains when work should be done on hand lathe, automatic lathe and on hot press.

SCREWS

Optical Work. Cutting and Gaging Screws. Machy. (Lond.), vol. 17, no. 428, Dec. 9, 1920, pp. 286–288, 4 figs. Method used by Taylor, Taylor & Hobson, Leicester, England. Table of tolerances for screw gages for optical work. Report of Committee of Department of Scientific and Industrial Research on Standardization of Elements of Optical Instruments.

Standards. Report of the German Industry Committee on Standards (Mitteilungen des Normenausschusses der Deutschen Industrie). Betrieb, vol. 3, nos. 3 and 4, Nov. 10 and 25, 1920, pp. 29–40 and 49–62, 31 figs. Nov. 10: Proposals of Board of Directors for square washers for channels and I-beams. Proposed new standards for Whitworth fine thread, metric fine thread, and sizes for paper sheets; Nov. 25: Proposals for Whitworth pipe threads; lock washer; square washers for wooden joints; knob screws and nuts. Proposed standards for set screws and of screws with slotted heads, set screws; metric extra-fine thread.

SEMI-STEEL CASTINGS

Experiments. Remarks on Semi-Steel Castings (Remarque sur la fonte aciérée). Fonderie Moderne, no. 11, Nov. 1920, p. 262. Experimental study of casting temperature.

SHAFT HANGERS

Reinforced-Concrete Plants. Securing Shaft Hangers to Beams in Reinforced Concrete Plants, S. R. Stone. Belting, vol. 18, no. 1, Jan. 1921, pp. 32–38, 15 figs. Providing for expansion of departments or changes. Preplanning necessary to avoid alterations. Sleeved slits for belt drives between floors.

SHAFTS

Whirling Speeds. The Transverse Vibrations of Beams and the Whirling of Shafts Supported at Intermediate Points, E. R. Darnley. Lond., Edinburgh & Dublin Phil. Mag., vol. 41, no. 241, Jan. 1921, pp. 81–96, 1 fig. Equations giving periods of transverse vibrations of uniform beams and whirling speeds of uniform shafts, when beams or shafts are simply supported at any number of intermediate points.

Torsional Oscillations. Torsional Oscillations of Transmission Shafts (Studio sulle oscillazioni torsionali degli alberi di trasmissione), Ottorino Sesini. Associazione nazionale degli Ingegneri italiani Giornale Ufficiale, vol. 1, no. 33, Nov. 30, 1920, pp. 255–260, 7 figs. Mathematical study.

SHIP PROPULSION

Air-Propeller. Hydrogliders and Barge Propelled by Air Propellers (Hydro-glisseurs et chalands a propulsion aerienne), René Pacaud. Revue de l'Ingénieur et Index Technique, vol. 27, no. 4, Oct. 1920, pp. 257–263, 3 figs. Technical application of air propeller to barges.

Hydro-Aerial Propellers. Hydro-Aerial Propulsion for Ships (Bateaux a propulsion hydro-aérienne), A. Breton. Nature (Paris), no. 2434, Nov. 27, 1920, pp. 351–352, 5 figs. Invention of M. A. Gambin. Two propellers are placed on parallel shafts in stern of ship. About $^1/_4$ of diameter of propellers goes under water, and propellers rotate in opposite directions. Reaction of stream of water sent against stern as well as propulsive action due to part immersed in water, propel the boat.

SHIP SALVAGE

Dredger. The Salvage of the Dredger "Silurus." Eng., vol. 111, no. 2871, Jan. 7, 1921, pp. 5–8, 11 figs. Vessel was 260 ft. by 46 ft. by 20 ft. She rested on her port bulwarks and top of port sheerstrake and with part of her funnel embedded in mud about 54 ft. below water level. Detailed account of salvage work. (To be continued.)

SHRINKAGE

Stresses in. Shrinkage Stresses in Hubs, Rings, Cranks, etc. (Strumpfspannungen in Naben, Ringen, Kurbelarmen, etc.), Karl Stösser. Der praktische Maschinen-Konstrukteur, vol. 53, no. 41–42, Oct. 14, 1920, pp. 353–359, 6 figs. Describes method for approximate determination of shrinkage stresses resulting from the hot and cold fitting of crank arms, hubs, rings, etc., to shafts; the stresses are shown graphically and an example is given.

SPRINGS

Helical. Chart and Simplified Formulæ for Helical Springs of Tempered Steel. Machy. (Lond.), vol. 17, no. 429, Dec. 16, 1920, pp. 318–319, 1 fig. Chart for determining carrying capacity, deflection and dimensions of tempered steel helical springs, tension or compression.

STANDARDIZATION

Machine Tools. The Effect of Standardization on Lathe Centers (Wirkung der Normung von Drehbankspitzen), H. Plumpe. Betrieb, vol. 3, no. 4, Nov. 25, 1920, pp. 94–97, 3 figs. An example is cited showing advantages of a comprehensive standardization of the parts of machine tools which must be frequently renewed.

System of Fit Allowances. A System of Fit Allowances, Sydney B. Austin. Machy. (N. Y.), vol. 27, no. 5, Jan. 1921, pp. 452–454, 3 figs. Curves showing relation of allowances for fits to various diameters. Comparison of theoretical curves with B. & S. system of fit allowances and with Newall Engineering Co.'s system of fits.

STEAM-ELECTRIC PLANTS

Design. Tendencies in the Design of Power Stations, Peter Junkersfeld. Elec. World, vol. 77, no. 1, Jan. 1, 1921, pp. 5–7, 5 figs. Economies resulting from skillful arrangement of station and layout of equipment and operating tendencies in boiler and turbine rooms. Survey of principal achievements in 1920.

France. The Electric Plant of the French State Railways at Nanterre, Seine (L'usine électrique des chemins de fer de l'etat à Nanterre (Seine), Lucien Pahin. Industrie électrique, vol. 29, no. 684, Dec. 25, 1920, pp. 466–470, 2 figs. Turbo generators of 5500 kw. each generating 3-phase current at 50,250 volts.

Signal Indicators. Adapting Signal Indicators to Power Plant Use, H. P. Sparkes. Elec. World, vol. 76, no. 26, Dec. 25, 1920, pp. 1251–1252, 2 figs. Apparatus consists of two synchronous motors connected so that when rotor of one transmitter, is placed in certain position rotor of other, indicator will be in exact synchronism and will thus indicate position at which transmitter is set. Apparatus was constructed during war for use on board U. S. Navy vessels and is being applied to transmitting signals from switchboard to boiler room in electric plants.

280,000-Kw. Building 280,000-Kw. Plant in New York City. Elec. World, vol. 77, no. 3, Jan. 15, 1921, pp. 140, 1 fig. Generator room adjacent to river to eliminate suction tunnels. Four units of 35,000 kw. each to be installed at outset.

STEAM ENGINES

A.S.M.E. Test Codes. Power Test Codes. Mech. Eng., vol. 43, no. 1. Jan. 1921, pp. 32–36, 1 fig. Preliminary draft of test code for reciprocating steam engines, formulated by Am. Soc. Mech. Engr. Test Code Committee.

STEAM TURBINES

Lubrication. The Lubrication of Steam Turbines (La lubrification et le système de graissage des turbines à vapeur), C. P. Roux. Revue générale de l'Électricité, vol. 8, no. 25, Dec. 18, 1920, pp. 870–872, 1 fig. Suggested specifications for oils and greases.

Small Machines. Small Steam Turbines, W. J. A. London. Proc. Engrs. Soc. Western Pennsylvania, vol. 36, no. 8, Nov. 1920, pp. 539–564 and (discussion) pp. 565–573, 15 figs. Study of reliability, simplicity, cost and efficiency. Turbines considered are those having output of from 5 to 300 hp.

STEEL

Defects. Defects Arising in Steel During Fabrication, Austin B. Wilson. Chem. & Metallurgical Eng., vol. 23, no. 25, Dec. 22, 1920, pp. 1209–1213, 24 figs. Microscopic appearances caused by surface defects, cold-working, overheating, and burning. Nuclei of fatigue fractures are associated with phosphorus bands. Photographs of changes in structure during annealing of steel castings are also given.

Magnet. On K. S. Magnet Steel, Kotaro Honda and Shozo Saito. Physical Rev., vol. 16, no. 6, Dec. 1920, pp. 495–500, 7 figs. Also Elecn., vol. 85, no. 2222, Dec. 17, 1920, pp. 706–708, 7 figs. Alloy developed in research work at Tokyo University. Composition is cobalt 30 to 40 per cent, tungsten, 5 to 9 per cent, and chromium $1^1/_2$ to 3 per cent. Tempering is best effected by heating to 950 deg. cent. and quenching in heavy oil. Measurements of residual magnetism for specimens of different composition gave values from 920 to 620 C. G. S. units; coercive force for same specimens ranged from 226 to 257 gauss.

Manganese. See MANGANESE STEEL.

Nickel. See NICKEL STEEL.

Nickel-Chromium. See NICKEL-CHROMIUM STEEL.

Research. Research on Steel Conducted in Germany During the War (Etudes faites en Allemagne durant la guerre, sur la connaissance des aciers), Gaston Paris. Chaleur et Industrie, no. 7, Oct. 1920, pp. 408–418, 10 figs. Influence of chemical composition and mechanical properties. Graphs showing properties of specimens subjected to different treatments.

Shock Values after Heat Treatment. Comparative Shock Values of Steel after Varied Heat Treatments, F. C. Langenberg and J. F. Fetterely. Army Ordnance, vol. 1, no. 2, Sept.-Oct. 1920, pp. 99–100. Results of tests.

Structural. See STRUCTURAL STEEL.

Welding. The Welding of Steel in Relation to the Occurrence of Pipe, Blowholes and Segregates in Ingots, Harry Brearley. Iron & Coal Trades Rev., vol. 101, no. 2755, Dec. 17, 1920, pp. 821–822. Experimental studies. Paper read before Cleveland Instn. Engrs.

Woody Fractures. The Woody Fracture in Steel (Ueber den Holzfaserbruch im Stahl), E. H. Schulz and J. Goebel. Stahl u. Eisen, vol. 40, no. 44, Nov. 4, 1920, pp. 1479–1485, 21 figs. With the aid of sample pieces the different formations of woody fractures in steel are discussed and it is shown that the causes therefor can be of very different origin. The two main groups of such fractures are described.

STEEL CASTINGS

Annealing. Anneal Steel with Pulverized Coal, C. H. Gale. Foundry, vol. 49, no. 1, Jan. 1, 1921, p. 29, 4 figs. Results of annealing steel castings with pulverized coal. Paper read before Am. Foundrymen's Assn.

Strength. Steel Castings of High Strength and Toughness—I, Frederico Giolitti. Chem. & Metallurgical Eng., vol. 24, no. 3, Jan. 19, 1921, pp. 113–118, 22 figs. Data on improvement to be expected after properly heat-treating steel castings, with illustrative tests on strong, tough castings which have replaced forgings on gun mounts. Advance copy of chapter of forthcoming book entitled, "Heat Treatment of Soft and Medium Steels."

STEEL MANUFACTURE

Electric-Furnace. Heat Modifies Acid Furnace Reaction, James W. Galvin and Charles N. Ring. Foundry, vol. 49, no. 2, Jan. 15, 1921, pp. 72–74. Electric furnace develops such high temperatures that chemical affinities in still are reversed. Steep sides with deep bath increase melting efficiency and compact charge is advocated.

STEEL WORKS

Coal Consumption. Coal Consumption in Steel Metallurgy (La consommation de charbon dans la grosse métallurgie). Génie Civil, vol. 77, no. 25, Dec. 18, 1920, pp. 499–503. Records of coal consumption of steel works producing 300,000 tons per year.

Two-Shift vs. Three-Shift System. The Three-Shift System in the Steel Industry, Horace B. Drury. Indus. Management, vol. 61, no. 1, Jan. 1, 1921, pp. 63–68, 5 figs. Survey of adoption of three-shift system in European countries, and account of its operation in about 20 American plans where it has been adopted. Paper read before Taylor Society.

STREET RAILWAYS

Brakes. See BRAKES, Street-Car.

STRESSES

Determining by Polarized Light. Determining Stresses by Polarized Light, George Weed Hall and Arthur L. Kimball, Jr. Sci. Am. Monthly, vol. 3, no. 1, Jan. 1921, pp. 49–53, 7 figs. Apparatus which permits visualization of stress distribution.

Stress Determination by Means of the Coker Photo-Elastic Method, A. L. Kimball, Jr. Gen. Elec. Rev., vol. 24, no. 1, Jan. 1921, pp. 73–81, 13 figs. Optical system for determining stress by polarized light.

Safe Loads. Chart for Determining Safe Loads, J. B. Conway. Am. Mach., vol. 53, no. 27, Dec. 30, 1920, pp. 1241–1242. Chart for determining safe load for parts in tension, compression and shear where part does not exceed in length, ten times its diameter. Chart is based upon formula for determining safe load in different materials.

Study of. Plane Stress and Plane Strain in Bipolar Co-Ordinates, G. B. Jeffery. Philosophical Trans. Royal Soc. Lond., vol. 221, series A, Aug. 11, 1920, pp. 265–293, 4 figs. Mathematical study.

Theories. Comparison of the Extension and Shearing Stress Theories (Beitrag zum Vergleich der Dehnungs- und Schubspannungstheorie), H. Boote.

ENGINEERING INDEX (Continued)

Zeit. des Vereines deutscher Ingenieure, vol. 64, no. 51, Dec. 18, 1920, pp. 1071–1073, 7 figs. The sudden yielding of the test pieces of ordinary soft low-carbon steel at upper yield point is used to demonstrate superiority of the formula for the simultaneous tensile and twisting stress over analogous formulas. Results of experiments are said to be particularly valuable due to fact that according to shearing stress theory, cross-sections would be greater, whereas the extension theory in this respect gives not only more correct values of stress, but also smaller construction weights.

STRUCTURAL STEEL

Specifications. Belgian Standard Specification for Structural Steelwork. Eng. News-Rec., vol. 86, no. 2, Jan. 13, 1921, pp. 71–72. Specifications for design and fabrication of steelwork for buildings and miscellaneous steel structures adopted by Belgian Standards Association.

T

TARGET

Towed, for Battleships. See WARSHIPS, Towing Target.

TERMINALS, RAILWAY

Management. Utilizing Motive Power on the Lines of the Delaware & Hudson. Ry. Rev., vol. 67, no. 26, Dec. 25, 1920, pp. 961–967. Methods of terminal management.

Operation. Railway Terminals and Terminal Yards, William Barclay Parsons. Mech. Eng., vol. 43, no. 1, Jan. 1921, pp. 21 and 62. Cost of terminal operation and possibilities of reducing it.

TESTS AND TESTING

Flexure. An Apparatus for Delicate Flexure Tests and Some Results of Such Tests, W. J. Francke. Am. Mach., vol. 54, no. 2, Jan. 13, 1921, pp. 48–52, 5 figs. Apparatus designed to test thin, tempered strip-steel shims used in flexible couplings. Paper read before Am. Soc. for Testing Matls.

Million-Pound Machine. Million Pound Testing Machine for Forest Products Laboratory, L. J. Markwardt. Eng. News-Rec. vol. 86, no. 1, Jan. 6, 1921, pp. 31–32, 2 figs. Machine is of two-screw type and has overall height of 45 ft., including superstructure above weighing platform, which will enable it to accommodate columns up to 30 ft. or tension members up to 27 ft. in length.

Motion Pictures, Use in. Motion Pictures in Physical Testing Laboratory, H. J. French. Chem. & Metallurgical Eng., vol. 24, no. 3, Jan. 19, 1921, p. 131, 4 figs. Application of moving-picture camera to testing of materials.

Notched-Bar Tests. Experimental Study of Notched-Bar Impact Tests (Étude expérimentale sur les essais au choc des barreaux entaillés), M. André Cornu-Thénard. Revue de Métallurgie, vol. 17, no. 10, Oct. 1920, pp. 648–667, 6 figs. Case of extra-mild steel crystallized in large drains. Photomicrographs. (Concluded.)

Photo-Elastic Testing. Photo-Elasticity for Engineers—III, E. G. Coker. Gen. Elec. Rev., vol. 24, no. 1, Jan. 1921, pp. 82–88, 10 figs. Discussion of photo-elastic investigation of testing materials in tension. It is shown that if enlarged ends of test bar are connected with parallel part by arcs of circle stress near joint of arc with parallel portion is somewhat greater than that in parallel portion.

THERMODYNAMICS

Carnot-Clausius Principle. Application of Carnot-Clausius Principle to Impact Waves in Elastic Solids (Application du principe de Carnot-Clausius aux ondes de choc des solides élastiques), E. Jouguet. Comptes rendus des Séances de l'Académie des Sciences, vol. 171, no. 19, Nov. 8, 1920, pp. 904–907. Conditions which Carnot-Clausius principle imposes on impact waves of solids when these waves originate discontinuities of not too great an amplitude.

TIDAL POWER

Development. Tidal Power Development, A. H. Gibson. Eng., vol. 110, nos. 2867–2868, Dec. 10–17, 1920, pp. 778–780, 6 figs., and 793–795, 11 figs. Outline of more promising schemes which have been suggested and patented.

Utilization of. Blue Coal (La houille bleue), R. Gouedard. Vie technique & industrielle, vol. 2, no. 13, Oct. 1920, pp. 17–24, 8 figs. Scheme for utilization of tidal power by means of low-head turbines. (Concluded.)

Report on Tidal Power. Engr., vol. 130, no. 3390, Dec. 17, 1920, pp. 614–615. Third interim report of Water Power Resources Committee appointed by British Board of Trade. Discussion of question of tidal power, with reference to project for utilizing 500,000 hp. of tidal energy in estuary of Severn River.

Studies in Tidal Power, Norman Davey. Engr., vol. 130, nos. 3388–3392, Dec. 3, 10, 17, 24 and 31, 1920, pp. 556–558, 578–580, 603–604, 634–636, and 652–654, 25 figs. Dec. 3: Classification and study of systems for conservation and use of tidal power; Dec. 10: Quantitative estimate of tide power cycles; Dec. 17: Analysis made of gross power available from tides under various systems of working, and change in this power factor examined under variations in tidal range; Dec. 24: Survey of tidal power available in England; and Dec. 31: Minimum constant hp. available from tides in England and Scotland is computed at 489,000 hp.; this value rising during springs to 1,555,000 hp. Gross totals of intermittent power are, minimum during neaps, 3,550,000 hp. and during springs, 15,300,000 hp.

Tidal Hydro-Electric Scheme for the Severn. Engr., vol. 130, no. 3388, Dec. 3, 1920, pp. 562–563, 1 fig. Discussion of scheme formulated by Civil Engineering Department of Ministry of Transport.

Utilization of Tidal Power and Energy of Wave Impact (Utilisation de la force des marées et du choc des vagues de la mer), H. Parenty and G. Vandamme. Comptes rendus des Séances de l'Academie des Sciences, vol. 171, no. 19, Nov. 8, 1920, pp. 896–898, 2 figs. Cement structure containing parallel cells along coastal region subjected to ebb and flow. Impact of water in cells compresses air in tanks behind cement structure.

Utilization of Tidal Power on the Coast of France (De l'utilisation des courants de marée sur les côtes de France), M. La Porte. Comptes rendus des Séances de l'Académie des Sciences, vol. 171, no. 24, Dec. 13, 1920, pp. 1205–1207. Study of points where utilization is most practicable.

TIME STUDY

Machining Operations. Determination of the Time Required for Machining Operations (Bestimmung der Arbeitszeiten für die Vorkalkulation im Maschinenbau), H. Eipel. Motorwagen, vol. 23, nos. 22 and 23, Aug. 10 and 20, 1920, pp. 409–413, 23 figs. 4 on 2 supp. plates. Calculating charts for determining time employed in turning and grinding, drilling and cutting thread, planing and slotting and milling and sawing.

Siemens-Schuckert Works. Application of Time Study in Large Industrial Plants (Anwendung der Zeitstudie im Grossbetrieb), C. W. Drescher. Betrieb, vol. 3, no. 5, Dec. 10, 1920, pp. 128–135, 7 figs. Describes practice and experiences in the electric motor plant of the Siemens-Schuckert Works.

TRACTOR ENGINES

Manufacture. Methods in a Tractor Engine Plant. Machy. (N. Y.), vol. 27, no. 5, Jan. 1921, pp. 424–427, 9 figs. Special machinery and unusual equipments for standard machine tools.

TRACTORS

Tests. More Results of Tractor Tests at Nebraska. Automotive Industries, vol. 43, no. 27, Dec. 30, 1920, pp. 1306–1308. Of Sixty-six tractors tested, eight have increased their rated engine speed, six lowered their horsepower rating, fourteen changed some item of equipment and three have withdrawn.

TRANSPORTATION

Coal Industry. The Transportation Problem in the Coal Industry, A. G. Gutheim. Ry. Age, vol. 69, no. 27, Dec. 31, 1920, pp. 1149–1152. Remarks of experience during war period.

Conditions in U. S. The New Era of Railroad Transportation in America, Lewis J. Spence. Ry. Age, vol. 69, no. 27, Dec. 31, 1920, pp. 1153–1154. Importance, both to carriers and shippers, of maintaining spirit of friendly coöperation. Paper read before National Industrial Traffic League.

Inland Waterways. Some Inland Waterway Transportation Problems, V. E. Lacy. Jl. Soc., Automotive Engrs., vol. 8, no. 1, Jan. 1921, pp. 59–62, 5 figs. Motive power for canal traction.

Railways. How the Need for More Motive Power Will be Met. Ry. Age, vol. 70, no. 1, Jan. 7, 1921, pp. 43–46, 3 figs. New locomotives, remodeled old locomotives and improved operation of all locomotives imperative.

Railroad Transportation, Daniel E. Willard. Mech. Eng., vol. 43, no. 1, Jan. 1921, pp. 17–18. Fundamentals for developing a complete and well-articulated national transportation system.

Repair Shop and Enginehouse Equipment Needs. Ry. Age, vol. 70, no. 1, Jan. 7, 1921, pp. 50–52. Large numbers of unserviceable locomotives and cars furnish strong argument for better facilities.

The Next Step Toward Preventing Depressions. Ry. Age, vol. 70, no. 1, Jan. 7, 1921, pp. 33–38, 11 figs. Stability of railway purchases offered as remedy by railway business association committee.

What Additions to Physical Property are Necessary? Ry. Age, vol. 70, no. 1, Jan. 7, 1921, pp. 39–43, 3 figs. Little increase in traffic possible without betterments in terminals and other facilities.

V

VALVES

Globe. Use and Abuse of Globe Valves. Ry. Rev., vol. 25, no. 67, Dec. 18, 1920, pp. 946–948, 2 figs. Recommends that railroads select one make of valve as standard for all their uses and maintain special globe valve repair and testing service.

Power Plants. Valves for Inconvenient Locations, Charles L. Hubbard. Power Plant Eng., vol. 25, no. 2, Jan. 15, 1921, pp. 111–115, 19 figs. Methods of reaching and operating in power plants.

VENTILATION

Ventilators. Recent Tests on Automatic Ventilators, A. J. Mack. Jl. Am. Soc. Heat. & Vent. Engrs., vol. 26, no. 9, Dec. 1920, pp. 849–853, 3 figs. Tests conducted by Engineering Experiment Station of Kansas State Agricultural College upon different types of ventilators. Effectiveness of different types when operated under varying conditions was studied, and comparative tests were made on syphon ventilator and those types not intended to produce any syphoning action.

VIBRATIONS

Study. The Photo-Radiograph, A. C. Banfield. Sci. Am. Monthly, vol. 3, no. 1, Jan. 1921, pp. 44–45, 6 figs. Instrument for study of vibrations.

W

WAGES

High. The Cost of Labor and the Labor-Cost, Elmer W. Leach. Am. Mach., vol. 53, no. 26, Dec. 23, 1920, pp. 1188–1189. Suggests that wages be kept up by reducing labor cost, that is increasing production per man.

WARSHIPS

Towing Target. The Metal Arc Welded Battle Towing Target Built at the Norfolk Navy Yard, James W. Owens and H. G. Knox. Welding Engr., vol. 5, no. 12, Dec. 1920, pp. 23–28. Constructed for experimental purposes by Bur. of Construction and Repair of U. S. Navy.

WASTE HEAT

Utilization. The Utilization of Exhaust Heat in Modern Factories (Abfallwärmeverwertung in modernen Betrieben), Ernst Blau. Der praktische Maschinen-Konstrukteur, vol. 53, nos. 37–38 and 39, Sept. 16 and 30, 1920, pp. 321–328 and 343–352, 21 figs. Details and illustrations of a number of recent German patents and devices for the utilization of waste heat from furnace plants, gas and Diesel engines, and from steam engines.

WASTE RECLAMATION

Industry. Utilization of Waste in Trade and Industry (Abfallwirtschaft in Industrie und Gewerbe) Betrieb, vol. 3, no. 4, Nov. 25, 1920, pp. 29–31. Gives working program proposed by the Bureau for handling the waste problem which was organized by the Committee for Economic Production (AWF) in conjunction with official authorities.

WATER HAMMER

Penstock. Water Hammer in Penstocks of High Reaction Turbines (Sur le coup de bélier dans les conduites forcées alimentant des turbines à forte réaction), M. de Sparre. Comptes rendus des Séances de l'Académie des Sciences, vol. 171, no. 18, Nov. 2, 1920, pp. 833–835. Modifications to be made in general formula for maximum water hammer in a conduit to make it applicable to case of penstocks.

Pipe Lines. Water Hammer in Pipe Lines, W. F. Durand. Eng. News-Rec., vol. 85, no. 26, Dec. 23, 1920, pp. 1212–1216, 6 figs. Studies extended to include effects of imperfect reflection at discharge end, friction, non-uniform change of valve opening and imperfect action of discharge opening as nozzle.

WELDING

Autogenous. See AUTOGENOUS WELDING.

Electric, Arc. See ELECTRIC WELDING, ARC.

Oxy-Acetylene. See OXY-ACETYLENE WELDING.

WELDS

Testing. The Testing of Welds in Steel Plates, S. W. Miller. Ry. Elec. Engr., vol. 12, no. 1, Jan. 1921, pp. 49–52, 9 figs. Conditions which affect quality of welds; simple bend test and etching of sections recommended. Paper read before Chicago Section, Am. Welding Soc.

WIND TUNNELS

Göttingen. German Wind Tunnels and Apparatus, Edward P. Warner. Aeronautics, vol. 19, no. 376, Dec. 30, 1920, pp. 468–469, 2 figs. Description of Göttingen wind tunnels. (To be continued.)

New Method of Testing Models. New Method of Testing Models in Wind Tunnels (Nouvelle méthode d'essai de modeles en souffleries aérodynamiques), W. Margoulis. Comptes rendus des Séances de l'Académie des Sciences, vol. 171, no. 31, Nov. 22, 1920, pp. 997–999. Also Aeronautics, vol. 19, no. 373, Dec. 9, 1920, pp. 412–413, 1 fig. Utilization of carbonic acid instead of air, at pressures and temperatures which are suitable and generally very different from those of surrounding atmosphere.

WOODWORKING MACHINES

Dovetailing Cutters. Dovetailing Machine Cutter Standards (Zinkenfräsernormalien), Otto Wenzel. Werkstattstechnik, vol. 14, no. 20, Oct. 15, 1920, pp. 535–536, 21 figs. Describes standard spindle cutter for use in dovetailing with a pitch of 1 in. or 25 mm. which are adapted to approximately uniform measurements in inches and millimeters.

Dust Collection. Efficient Dust-Collecting Systems. Wood-Worker, vol. 39, no. 10, Dec. 1920, pp. 30–32, 2 figs. Layout of dust-collecting systems in table factory.

WOMEN WORKERS

Adaptability. The New Place of Women in Industry—IV, Ida M. Tarbell. Indus. Management, vol. 61, no. 1, Jan. 1, 1921, pp. 51–58. Records of employment of women at International Harvester Co.

Telephone Industry. Women in Industry. Monthly Labor Rev., vol. 11, no. 6, Dec. 1920, pp. 117–125. Statistics of labor turnover and length of service in telephone industry in New York State.

The Present Trend of Turbine Development

A Brief Survey of Past History and Recent Progress, Together with a Discussion of Theoretical Problems Involved in the Hydraulics of the Modern High-Speed Turbine

By LEWIS F. MOODY,[1] PHILADELPHIA, PA.

IN order to gain some idea of the direction in which the development of the hydraulic turbine is tending, it is useful to consider the path by which the turbine has reached its present condition. There are a few phases of the turbine's evolution which are worth noting, and these will be briefly mentioned.

The early turbines, during the first half of the last century, were most frequently of the single-runner, vertical-shaft type, usually set in open flumes, and having, at the choice of the builder, outward-flow, axial-flow, or inward-flow runners. After about 1850 the turbine began to develop along more theoretical lines, and much highly creative work was done on it by such engineers as Howd, Swain and Francis in America and Fourneyron and Jonval in Europe.

As an example of the early turbine forms, Fig. 1 is given, showing one of the Geyelin-Jonval turbines built by the I. P. Morris Co. and installed at the Fairmount Water Works, Philadelphia, in 1860. The regulation was furnished by a cylinder gate at the discharge from the draft tube.

Upon the advent of electrical power, the turbine began to experience rapid evolution. The requirements for driving electrical generators immediately called for great increases in the capacities of turbine units, and also demanded increases in speed. The simple form of single-runner, vertical-shaft turbine, such as that of Fig. 1, began to receive elaboration. At first two runners, and then still more runners were placed on a single shaft, and the vertical arrangement of shaft was abandoned in favor of horizontal-shaft units, as many as eight runners sometimes being placed in a single turbine.

The demands for close regulation of speed in the development of electrical power led to the improvement of gate mechanisms, and this also produced complication. Instead of the early cylinder and register gates, wicket-gate or movable-guide-vane regulation was introduced, requiring a material increase in the number of moving parts and the amount of mechanism.

The increasing demands for large amounts of electrical energy caused a corresponding increase in the size of units, and this phase of development of the turbine has continued practically without interruption; and there are no indications that the peak has yet been reached. With the growth of unit capacities, the importance of the turbine and its engineering problems increased correspondingly. When the turbine had reached a size such that any interruption of a single unit's service, due to a breakdown, or to such troubles as blocking by trash or ice, would involve a loss of 10,000 or 20,000 hp., it no longer became desirable to install a low grade of machinery nor to place many of the working parts within the water passages where they would be inaccessible for inspection, lubrication, adjustment or repair. The direction of evolution then took the form of a return to a simpler machine, and it no longer became the style to place four or six runners in a flume, each runner having twenty or more separate movable guide vanes, with a large number of the parts of the mechanism for operating them entirely submerged.

[1] Consulting Engineer, I. P. Morris Department, The William Cramp & Sons Ship and Engine Building Company. Mem.Am.Soc.M.E.

Presented in Philadelphia Jan. 21, 1921, at a Symposium on Hydro-electric Development and Distribution, held under the auspices of the Engineers' Club of Philadelphia and the Philadelphia Sections of the American Society of Civil Engineers, the American Institute of Electrical Engineers and The American Society of Mechanical Engineers. Slightly condensed.

One of the notable installations in which this direction of development was followed to its logical conclusion was that of the Appalachian Power Co., including two plants having turbines all of the same design, these turbines being of the vertical-shaft, single-runner type, installed in volute casings formed in the concrete substructure of the power house. The Appalachian turbines (Fig. 2) were completed in 1912, and were the forerunners of a large number of notable installations which have followed all of the principal features exemplified by the Appalachian turbines, including the use of a cast stay-vane ring or so-called "speed ring" set in the concrete to stay the upper and lower walls of the casing together and to support the superimposed structure, a thrust bearing located above the generator to carry the revolving weights, and operating mechanism of the outside type placed in an open turbine pit in an easily accessible position, actuated by a hydraulic cylinder placed just above the turbine head cover.

When turbines of this type are built in the enormous sizes which are being adopted today, there is little possibility of the turbine being subjected to enforced shutdowns due to any accidental cause, such as trash or ice lodging in the runner or guide vanes, and the ruggedness of the machine, due to its being composed of a small number of heavy parts, provides strong assurance of operation through many years of continuous service. All working parts are accessible for lubrication. The size of these turbines in itself makes them independent of most of the ordinary vicissitudes.

In most of the early turbines no draft tubes were provided, the outflow loss from the runner being limited to small values and no attempt being made to regain the energy of the discharge. Straight draft tubes were then introduced with the vertical single-runner turbines, but in the multiple-runner units the use of several draft tubes in a single tail-race chamber frequently interfered with the flow, often introducing a serious loss of head. In many units curved draft tubes were adopted, of quarter-turn or elbow form, and in horizontal-shaft units central discharge draft chests were used common to a pair of runners. The elbow type of draft tube, however, was inherently unsuited to handle a whirling discharge from the runner, such as exists in turbines of high specific speed at all gate openings, and at part gate in all turbines.

With the adoption of the single-runner, vertical-shaft turbine, it became possible to provide volute casings in which the velocity of flow could be definitely determined at every point and all sudden changes in direction or velocity avoided. With the recent introduction of draft tubes which are symmetrical about the turbine axis, and the elimination of the elbow form of passage, it is now possible to conduct the water from intake to discharge without disturbances or eddy formation at any point.

The same sort of progress has taken place in the design of the guide vanes and runner. From the simple radial- or axial-flow types of guides and runners, the effort toward increased speeds and capacities resulted in the adoption of so-called "mixed-flow" runners with complicated forms of wheel vanes, the water changing in direction from inward to axial or even to outward flow within the runner. A series of such runners of modern type is shown in Fig. 3, the largest being one of the runners for the Cedars Rapids Mfg. & Power Co., P. Q., Canada, and the largest ever built.

In turbines of extremely high specific speed, suited for use under very low heads and for small powers, where efficiencies can be sacrificed to some extent to secure a lower first cost, there has been a return to simpler runner types, including the purely diagonal-

and the axial-flow runner. Such types seemed the logical development of the process of cutting back more and more the vanes of the high-speed "mixed-flow" runner. The trend of development has thus been toward a turbine in which there is a more gradual change in the direction of flow within the runner, the runner being closely related to the simpler types which preceded the mixed-flow runners. This change has simplified both the lines of flow and the forms of the runner vanes.

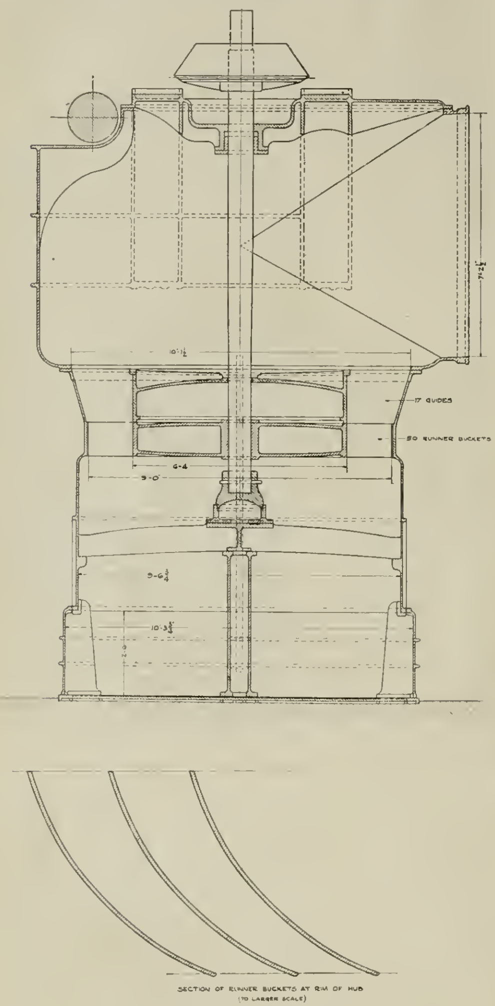

Fig. 1 I. P. Morris Company Turbine Installed at Fairmount Water Works, Philadelphia, in 1860

With the adoption of the mixed-flow type of turbine, academic methods of calculating the hydraulic elements of the design became less and less applicable, and for a number of years hydraulic engineers have been greatly handicapped by the lack of any satisfactory method of rational design due to the complicated form which the turbine has assumed, together with the natural difficulties inherent in practically every hydraulic problem. Little enough is known about the flow of water in simple forms of stationary conduits, and there are many uncertainties involved in the complex problems of hydraulic machines having rotating water passages such as the turbine and centrifugal pump. The theories given in the textbooks are not of much help in designing the turbines of today.

The writer believes that it will be worth while to give attention to some of the theoretical problems involved in the hydraulics of the modern turbine. Without attempting to develop a complete theory, a few considerations or "speculations" will be explained below which have a bearing on the further development of the turbine. In particular, it will be of interest to look into the possibilities of securing further increases in specific speed without undue sacrifice of efficiency.

Chief Elements of the Modern Turbine

The chief elements of the turbine of the present, and probably of the immediate future, are:

1 A casing in which the water can approach the runner symmetrically with respect to the axis on all sides, without any obstructions or enforced abrupt changes of flow which would introduce eddies or unsymmetrical distribution of velocity. The spiral or volute casing meets these conditions, and in most cases is the most satisfactory form of intake. On account of the increase in the velocity of the water from a low value in the intake to a high value where it passes through the runner, the water passage must contract radially as it approaches the runner, and must subsequently expand again. The approach of the water to the runner therefore involves a radial component of flow toward the axis;

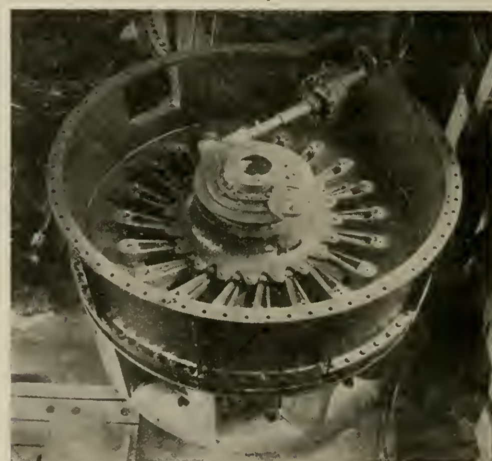

Fig. 2 Turbine for Appalachian Power Company, 1912, Erected in Shop

and by so-called "speed vanes" or stay vanes and by the movable guide vanes or gates the water is given increasing whirl or rotational components of motion about the axis as it nears the runner. After leaving the guide vanes the water continues to increase in velocity of whirl due to its closer approach to the axis, and at the same time it turns in the meridian plane and takes the axial direction either just before, during, or just after its passage through the runner.

2 A wide transition space is provided between guide vanes and wheel vanes, and in this space the water can come together in a continuous whirling mass before entering the runner. In a high-specific-speed turbine the water continues to contain whirl components of motion, but of somewhat reduced amount, after leaving the runner, even when the turbine is operating at its point of best efficiency.

3 After leaving the runner the water continues to flow as a whirling, axially advancing stream in a draft tube having a straight axis coincident with that of the turbine, and conical or flaring walls, this form of tube continuing, if what the writer believes to be the best practice is followed, until the velocity head has been reduced

by diverting the flow into other directions or by many discharging the water.

The turbine may be viewed as a water passage having walls which are surfaces of revolution and containing a continuous body of water which is both whirling and progressing with radial and axial velocity components, in which is placed a runner which develops torque by reducing, but not necessarily destroying, the whirl components of the flow. If a draft tube is used which is capable of regaining a considerable part of the energy due to the whirl components as well as that due to the axial components of the velocity of discharge from the runner, a result which can actually be secured, the "outflow loss" from the runner is reduced to a small fraction of that which enters into the usual textbook formulas.

The conditions of flow in the transition space in advance of the runner and in the draft tube, as well as the action of the water on the runner, can be usefully treated by means of the following method:

Consider the steady flow of water through a passage (Fig. 4) bounded by surfaces of revolution, and imagine the water to be given an initial whirl either by guide vanes or volute casing or equivalent means. Let us center our attention upon the annular space marked by double hatching. This ring is continually filled with water which is flowing in through its outer cylindrical surface of radius r_1 and out through its inner surface of radius r_2; and at any particular point in the space the velocity, pressure, etc., will be the same from instant to instant, since steady flow is being

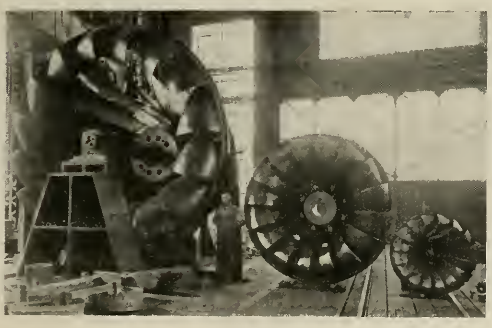

Fig. 3 Mixed-Flow Turbine Runners of Modern Type

considered. There will therefore be no change with respect to time in the conditions within the ring-shaped space; so that this ring of water is in equilibrium, and is acted on by balanced forces, with zero acceleration.

If the water enters the space with velocity c_1, having a circumferential component c_{u1}, and leaves with velocity c_2 having a circumferential component c_{u2}, then, applying the well-known principle that the "impulse" or force exerted by W lb. of water of velocity V is WV/g, we shall have the moment exerted upon the ring of water by the entering streams, about the axis, equal to $Wc_{u1}r_1/g$, in which W is the total weight of water entering the ring per second. In the same manner the moment due to the backward reaction of the leaving stream is $Wc_{u2}r_2/g$, the amount of water leaving being the same as that entering in accordance with continuity of flow. The two moments must be equal and opposite, since otherwise the ring of water would indefinitely increase in velocity; so that neglecting the frictional resistance of the walls, we have for steady flow

$$\frac{Wc_{u1}r_1}{g} = \frac{Wc_{u2}r_2}{g}, \text{ or } r_1 c_{u1} = r_2 c_{u2}$$

This relation will apply in any unobstructed space of revolution, whether the flow is inward, axial, or outward. The principle is not new. It was known in the case of a vortex to Leonardo da Vinci.[1]

[1] Forchheimer, Hydraulik, p. 285.

radius. We can illustrate the use of this law by applying it to the familiar case of a free vortex in an open basin. If we neglect the components of velocity in the meridian plane and assume for an approximation that the velocity is entirely in the circumferential direction we shall have, referring to Fig. 5, $v = k/r$, r being the radius to any point in the surface and k a constant; and if z is the

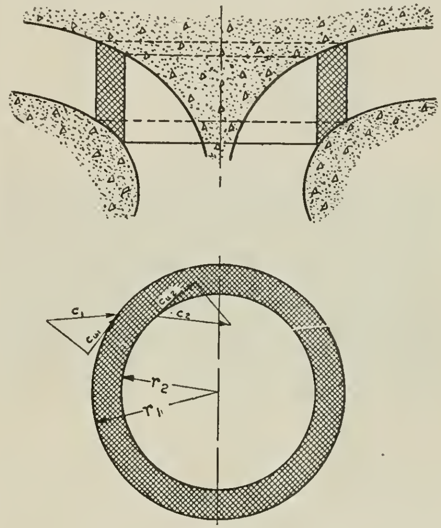

Fig. 4 Flow in Transition Space in Advance of Runner and in Draft Tube

ordinate of the same point, then since the pressure at every point of the surface is atmospheric, and since therefore the velocity head must increase by the same amount that the elevation head decreases, we shall have $z = v^2/2g$. Combining the above expressions we have $r^2 z =$ (a constant). This is the equation of a third-degree hyperbola, which agrees closely with the surface of a free vortex.

It is interesting to note that where there is a whirl component of velocity in the flow in such spaces of revolution there must be a surface of discontinuity bounding the flowing stream, similar to the surface of the above vortex, since if the flow should approach the axis more closely the velocity of whirl would be required by the above relation to approach infinite values. When the space within the surface of discontinuity is filled with water it is likely that this water is set into an eddying condition without partaking of the general flow of the surrounding stream.

The Spreading Type of Draft Tube

The principle just explained suggests a useful method of regaining the kinetic energy of the whirling component of flow in the water discharged from a turbine runner or pump impeller. For example, if the flow is turned into an outward direction, away from the axis, the velocity of whirl will diminish in inverse proportion to the increasing radius, and the corresponding velocity head will diminish inversely as the square of the radius, so that it is merely necessary to lead the water a moderate distance away from the axis to obtain the conversion of a large proportion of the velocity head of whirl into pressure head. This principle is used in the spreading type of draft tube.

The construction of this tube can be understood from Fig. 6, which shows a model of the draft tubes of the 30,000-hp. turbines for the United States Government Plant at Muscle Shoals, Alabama.

In utilizing this principle in the design of a turbine draft tube the meridian components of flow must not be lost sight of, and sufficiently gradual reduction in the meridian components must be provided, without sudden changes in direction. Both for the

avoidance of rapid changes in velocity and direction of the meridian components, and also to avoid a surface of discontinuity and the presence of a region of eddies, the value of including in the draft-tube design a central cone or core is clear. When a turbine draft tube is short, and when a long and awkward structure is not required to do it, it may be advisable to carry the central core up to the runner discharge, thus avoiding all flow close to the axis where the tendency to form a vortex or vortices is great. The writer also suggests the use of continuously curved inner and outer

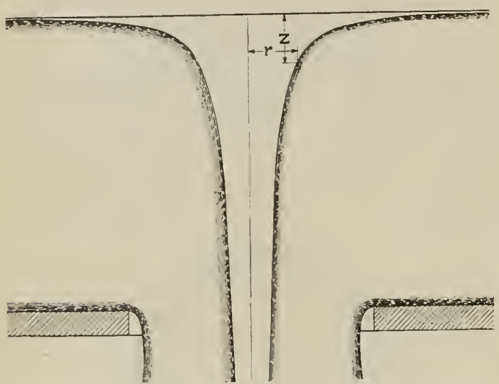

Fig. 5 Vortex Flow in Unobstructed Space of Revolution

surfaces of revolution for the turbine water passage, thus avoiding all sudden changes in curvature. Fig. 7 shows in outline a turbine which follows these principles.

A New Form of Turbine

In this new turbine form the entrance passage merges into the

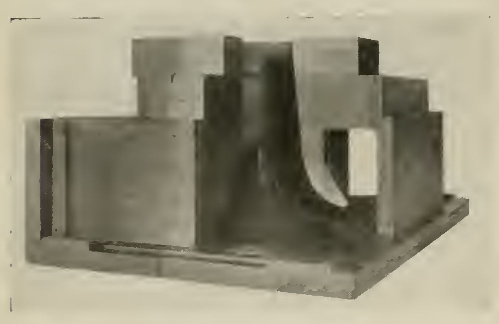

Fig. 6 Model of Spreading Draft Tube of 30,000-hp. Turbines at Muscle Shoals Plant

runner space and the latter merges into the draft tube, and the flow passes into the draft tube by a continuous gradation, with gradual changes in the whirl about the turbine axis and without sudden variations of the secondary whirl occurring in the meridian plane, i. e., the plane of the figure.

If a ring of vanes such as a runner is interposed in the revolving mass of water, the torque exerted on the vanes by the water is equal to

$$\frac{W}{g}(r_1 c_{u1} - r_2 c_{u2}).$$

New forms of runner suited to the new types of high-speed turbine here considered are shown in Fig. 8, which may be contrasted with the series of runners of the more usual type shown in Fig. 3.

Draft-Tube and Runner-Vane Friction Losses

Taking up some of the theoretical conditions presented by the modern forms of turbine, it will be recalled that in practically all of the time-honored turbine theories the design is based on the radial or axial direction of discharge from the runner; that is, for the conditions of best efficiency the absolute direction of outflow from the runner is assumed to be in a meridian plane, a plane containing the axis. That this is not actually the best direction of discharge for high-speed runners has been known for several years, as found from pitot-tube and direction-vane investigations in draft tubes.

With the use of the earlier forms of draft tube any direction of discharge having a whirl component introduced uncertainties and complications in the formulas, and the problem was not attractive. With the use of a draft tube capable of efficiently regaining the energy of whirl components as well as of meridian components of flow, however, it becomes possible to formulate some simple relations which it will be interesting to investigate. For one thing we shall no longer have to make the outflow loss from the runner dependent upon the direction of discharge, since we can use a draft tube which will handle the whirl components just as efficiently as the meridian components; the outflow loss from the runner can therefore be expressed as a function merely of the amount of the discharge velocity regardless of its direction. If the draft-tube efficiency is e_d and the coefficient of loss in the draft tube f_3, the portion of the velocity head of the water discharged from the runner which is lost or dissipated will be $f_3c_2^2/2g$; c_2 being the absolute velocity of discharge from the runner and $f_3 = 1 - e_d$.

In runners of high specific speed another important loss is that due to the frictional resistance of the runner vanes, since very high relative velocities between the vanes and water are employed. In recent forms of high-speed turbines, such as just shown in Fig. 8, the rotational speed is high and the torque correspondingly low, so that the runner vanes have but little curvature and deflect the water only in small amounts. The loss of head due to the frictional resistance of the runner vanes can be expressed as $f_2w_2^2/2g$, in which w_2 is the relative velocity with which the vanes move through the water, measured at their outflow edges. (For the reason just

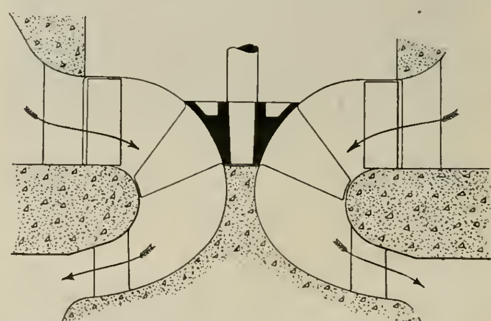

Fig. 7 A New Form of Turbine

mentioned, however, the relative velocity is nearly the same over the whole vane.)

Instead of making any arbitrary assumption regarding the direction of discharge upon which to base our turbine design, it will be useful to find the conditions which will give the minimum value for the sum of the above two losses—the outflow loss from the runner and the resistance loss in the runner. The problem may be stated as the determination of the conditions for maximum efficiency for a given specific speed or of maximum specific speed for a given efficiency.

Before proceeding with the problem itself, a distinction between two expressions for specific speed now in use should be explained. The usual formulation for specific speed used in turbine work is $N_s = N\sqrt{\text{hp.}}/H^{5/4}$. This form of specific speed is useful in turbine work because we most frequently have to fix the turbine

the specific speed as $N_s = N\sqrt{Q}/H^{3/4}$, since the discharge and head are usually the known quantities. The two expressions are derived from the same dimensional relations and the second is just as applicable to turbines as to pumps, and the first as applicable to pumps as to turbines. Let us distinguish by calling the specific speed based on quantity $N_{sQ} = N\sqrt{Q}/H^{3/4}$. Although in adapting turbines of types already developed to new requirements of head and power the first expression is more convenient, the second has advantages when the problem is the development of a new design or type, since by its use we may design for a desired discharge under a definite head without introducing unnecessary uncertainty by having to assume an efficiency in advance. Moreover, if the efficiency should turn out to be materially different from that expected, the discharge and velocities will not be thrown so far out of agreement with the designed values if taken for a given N_{sQ} as they would be if taken for a given N_s. In stepping a small turbine up to a larger size the N_{sQ} will remain more nearly constant than the N_s.

In the problem in hand we will gain simplicity by employing N_{sQ}, and if we determine the conditions for maximum N_{sQ} for a given efficiency we shall at the same time have found those for the maximum N_s, since

$$N_s = \sqrt{\frac{62.4}{550}} \times N_{sQ}\sqrt{e}$$

and the conditions which will give the best efficiency for a given N_{sQ} will also give the best efficiency for a given N_s.

The writer might mention, in passing, his belief that the knowledge of hydraulics has gained more from the study of dimensional relations such as the principles of similarity and specific speed than from any other method; and it may not be altogether fanciful to think of these relations as corresponding in a minor degree with the "relativity" movement in abstract philosophy.

To resume the problem of finding the conditions for the maximum value of the sum of the two losses mentioned, the "outflow triangle" of velocities is drawn as in Fig. 9(a) with the velocities marked to show the notation which is here used (the system which has now become standard in Europe).[1]

The form of the triangle can easily be related to the specific speed by putting $U_2 = \pi D_2 N/60\sqrt{2gH}$ and $C_{m2} = Q/A\sqrt{2gH}$, in which A is the area of the turbine passage at the runner discharge measured normally to C_{m2}.

Then

$$N_{sQ} = \frac{60\sqrt{2gH}}{\pi D_2} U_2 \frac{\sqrt{AC_{m2}\sqrt{2gH}}}{H^{3/4}} = \frac{60(2g)^{3/4}\sqrt{A}}{\pi D_2} U_2\sqrt{C_{m2}}$$

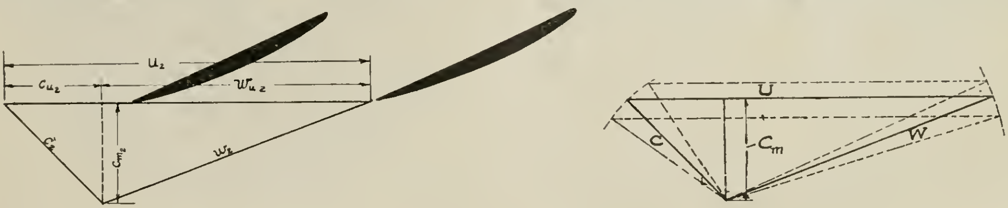
or, dropping subscript ($_2$), $k_{sQ}\,N_{sQ} = U\sqrt{C_m}$, in which

$$k_{sQ} = \text{a constant} = \frac{\pi D_2}{60\,(2g)^{3/4}\sqrt{A}}$$

Before considering the problem with reference to the amounts of the vane loss and outflow loss, we can reach an interesting con-

Fig. 8 New Forms of Runner Suited to New Types of High-Speed Turbine

clusion simply by supposing that the magnitude of the absolute and relative velocities C and W are kept constant while their directions are changed until the most advantageous shape of outflow triangle is attained. As shown in Fig. 9(b) various shapes of outflow triangle can be drawn with the same values of C and W, and therefore with the same losses of head. There will be one of these triangles which will give the highest specific speed, which we have



(a) (b)

Fig. 9 Outflow Triangle of Velocities

Velocity of runner vanes = $u_2 = (\pi D_2/60)N$. Meridian velocity component of water = $c_{m2} = Q/A$. Specific speed based on quantity = $N_{sQ} = N\sqrt{Q}/H^{3/4} = (60\sqrt{A}/\pi D_2 H^{3/4})u_2\sqrt{c_{m2}}$

Here c_2 = absolute discharge velocity from runner
w_2 = relative discharge velocity from runner
u_2 = velocity of runner
c_{m2} = meridian component of velocity of discharge
c_{u2} = whirl component of absolute velocity of discharge, which may we call the "absolute whirl," and
w_{u2} = whirl component of relative velocity of discharge which we may call the "relative whirl."

Since we are not concerned with any particular value of the head, we can adopt a "specific" value for each velocity, using the device of Thomann,[2] which is convenient in problems of this kind, and call

$$C_2 = \frac{c_2}{\sqrt{2gH}};\ W_2 = \frac{w_2}{\sqrt{2gH}};\ U_2 = \frac{u_2}{\sqrt{2gH}},\ \text{etc.}$$

[1] See Camerer, Wasserkraftmaschinen, 1914, pp. iv, vii and viii.
[2] R. Thomann, Die Wasserturbinen, 1908, pp. 11–12.

just seen is proportional to $U\sqrt{C_m}$. To find the relation which will thus give the maximum N_{sQ} for a given loss, we can put

$$k_{sQ}\,N_{sQ} = U\sqrt{C_m} = (\sqrt{C^2 - C^2_m} + \sqrt{W^2 - C^2_m})\sqrt{C_m}$$

and considering C and W to be constant, we can differentiate $(k_{sQ}\,N_{sQ})$ with respect to C_m and equate to zero:

$$\frac{k_{sQ}\,dN_{sQ}}{dC_m} = (\sqrt{C^2 - C^2_m} + \sqrt{W^2 - C^2_m})\frac{1}{2\sqrt{C_m}} - \sqrt{C_m}\left(\frac{C_m}{\sqrt{C^2 - C^2_m}} + \frac{C_m}{\sqrt{W^2 - C^2_m}}\right) = 0$$

From this we have, simplifying,

$$\sqrt{C^2 - C^2_m} + \sqrt{W^2 - C^2_m} = 2C^2_m\left(\frac{1}{\sqrt{C^2 - C^2_m}} + \frac{1}{\sqrt{W^2 - C^2_m}}\right)$$

and substituting C_u for $\sqrt{C^2 - C^2_m}$ and W_u for $\sqrt{W^2 - C^2_m}$,

$$C_u + W_u = 2C^2_m\left(\frac{1}{C_u} + \frac{1}{W_u}\right); \text{ or } U = 2C^2_m\left(\frac{W_u + C_u}{C_uW_u}\right) = \frac{2C^2_mU}{C_uW_u}$$

which gives $C_m = \sqrt{C_uW_u/2}$ as the most advantageous proportion. That is, the meridian velocity should be chosen as 0.707 multiplied by the mean proportional of the absolute whirl and relative whirl. In calculations applying to the runner as a whole, the velocities corresponding to an average point in the runner may be used, such as the center of area of a sector of the discharge space.

Fig. 10 enables us to visualize the meaning of this relation.

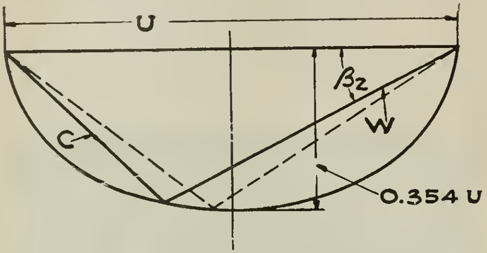


FIG. 10 DIAGRAM SHOWING PROBABLE POINT OF BEST OPERATION FOR RUNNER WITH VANE INCLINATION β_2

The vertex of the outflow triangle should fall somewhere on the ellipse of major axis U and semi-minor axis =

$$0.707\sqrt{\frac{U}{2} \times \frac{U}{2}} = 0.354\ U$$

For example, if a runner has a vane inclination β_2 its probable

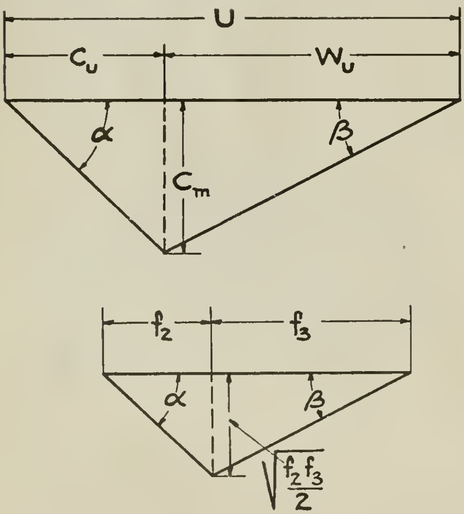

FIG. 11 RELATIONS OF VARIOUS OUTFLOW VELOCITIES FROM THE RUNNER TO EACH OTHER

point of best operation can be found by drawing W at this angle with the base line and completing the triangle with the vertex at the point where the W line intersects the ellipse. According to this diagram, it would evidently never pay, from the standpoint of efficiency alone, to use a meridian velocity greater than 35.4 per cent of the circumferential velocity of the runner. Since the meridian velocity may be somewhat increased, however, before the efficiency is seriously impaired, it will probably be economical to use slightly higher values of C_m than are called for by this relation, in order to reduce the turbine dimensions and cost.

Now proceeding with the problem, and considering the amounts of the losses of head, we can derive some useful relations, as follows:

From the above expression for specific speed, we see that we can keep the length of base U of the outflow triangle and its altitude C_m constant, and can change its shape without changing the specific speed. By shifting the vertex parallel to the base, there must be some position which will make the sum of the outflow loss and vane resistance loss a minimum.

Calling the sum of these losses H_L, the loss of head expressed as a fraction of the effective head is

$$h_L = \frac{H_L}{H} = f_2\frac{w_2^2}{2gH} + f_3\frac{c_2^2}{2gH} = f_2W^2 + f_3C^2$$

Expressing h_L in terms of U, C_m and C_u,

$$\begin{aligned} h_L &= f_2W^2_u + f_3C^2_u + (f_2 + f_3)C^2_m \\ &= f_2U^2 + f_2C^2_u - 2f_2\,UC_u + f_3C^2_u + (f_2 + f_3)C^2_m \\ &= f_2U^2 + (f_2 + f_3)C^2_u - 2f_2UC_u + (f_2 + f_3)C^2_m \end{aligned}$$

For a given U and C_m we can find the value of C_u which will make h_L a minimum, neglecting the effect of any small variation of f_2 due to a change in direction of W as being of a higher order of small quantities than differences in the losses themselves. Then

$$\frac{dh_L}{dC_u} = 2(f_2 + f_3)C_u - 2f_2U = 0$$

That is,

$$C_u = \frac{f_2}{f_2 + f_3}\,U, \text{ or } f_2(U - C_u) = f_3C_u$$

from which

$$f_2W_u = f_3C_u, \text{ or } \frac{C_u}{W_u} = \frac{f_2}{f_3}$$

This means that for the best efficiency the absolute whirl should

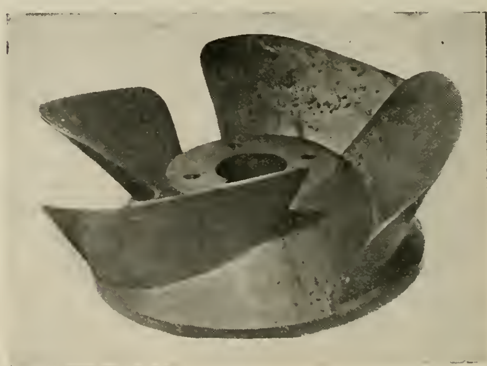

FIG. 12 NEW TYPE OF HIGH-SPEED PUMP IMPELLER

be to the relative whirl as the coefficient of frictional loss is to the coefficient of outflow loss.

The above result shows for one thing that in a runner for which f_2 is large, as is the case in runners having a large amount of vane surface—particularly when this surface is increased by an outer band—the best condition of operation will be with comparatively low relative whirl and high absolute whirl, so that such runners will discharge the water at a greater angle of inclination to the meridian plane than runners having less vane surface and correspondingly lower f_2. The numerical value of f_2 can be calculated by figuring the loss of head in the runner buckets considered as rectangular channels. The purpose of this investigation is not so much to take up questions of design and calculation, however, as to establish some of the controlling relations, and we will give less attention to the numerical values of the coefficients than to the general conclusions which may result.

Having established the above relation between the relative whirl and absolute whirl at the runner discharge, we can now proceed, assuming that the said relation is to be complied with,

$$h_L = f_2U^2 + (f_2 + f_3)C^2{}_u - 2f_2UC_u + (f_2 + f_3)C^2{}_m$$

by expressing C_u in terms of U according to the result just obtained above, namely, $C_u = [f_2/(f_2 + f_3)]\,U$, we have

$$h_L = \frac{f_2f_3}{f_2 + f_3}\,U^2 + (f_2 + f_3)C^2{}_m.$$

Substituting in this

$$U = k_{sQ}N_{sQ}/\sqrt{C_m}$$

we have

$$h_L = \frac{f_2f_3}{f_2 + f_3} \times \frac{k^2{}_{sQ}N^2{}_{sQ}}{C_m} + (f_2 + f_3)C^2{}_m$$

To obtain the conditions for minimum h_L for a given N_{sQ} we will differentiate the last expression with respect to C_m, considering N_{sQ} a constant, and will equate the derivative to zero:

$$\frac{dh_L}{dC_m} = -\frac{f_2f_3}{f_2 + f_3} \times \frac{k^2{}_{sQ}N^2{}_{sQ}}{C^2{}_m} + 2(f_2 + f_3)C_m = 0$$

outflow velocities from the runner should therefore be related to each other in the proportions shown at the top in Fig. 11, which is geometrically similar to the outflow diagram as indicated in the lower part of the same figure. That is, C_u, W_u, C_m and U should be to each other respectively as f_2, f_3, $\sqrt{\frac{f_2f_3}{2}}$ and $(f_2 + f_3)$.

From the last-mentioned figure it is seen that

$$\tan\beta_2 = \sqrt{\tfrac{1}{2}\frac{f_2}{f_3}} \text{ and } \tan\alpha_2 = \sqrt{\tfrac{1}{2}\frac{f_3}{f_2}}$$

In order to use advantageously small values of β_2, to secure runners of very high specific speed, it therefore becomes necessary to obtain low values of f_2, and thereby to avoid the necessity for high angles of whirl at the runner discharge. These small values of f_2 can be secured by reducing the exposed runner surface to a minimum. If this reduction of vane area is carried too far, how-

from which, replacing $k_{sQ}N_{sQ}/\sqrt{C_m}$ by U, we have

$$2(f_2 + f_3)C_m = \frac{f_2f_3}{f_2 + f_3} \times \frac{k^2{}_{sQ}N^2{}_{sQ}}{C^2{}_m} = \frac{f_2f_3}{f_2 + f_3}\,\frac{U^2}{C_m}$$

From this we obtain

$$\frac{C_m}{U} = \frac{\sqrt{{}^1/_2(f_2f_3)}}{(f_2 + f_3)}$$

The same result is called for by the relation $C_m = \sqrt{C_uW_u/2}$, already given, if we insert

ever, another source of loss will be introduced due to permitting the passage of a considerable portion of the flow between the vanes without its acting effectively upon them.

The foregoing relations are as applicable to pumps as to turbines, and furnish a helpful guide in proportioning the absolute whirl, the relative whirl and the meridian velocity component in designing both turbines and pumps of high specific speed. Fig. 12 shows a new type of high-speed pump impeller.

In looking forward to the future development of the turbine, it can be seen from the foregoing that theoretic considerations

call for a conservative proportioning of the various velocities and angles of the turbine, and that there is no apparent means of greatly increasing specific speeds merely by using some new and radical proportion between the velocities. Efficiencies are already so high that no startling increase is possible. The prospect of further increases in specific speed therefore lies entirely in the use of higher velocity heads in comparison with the head on the plant, and an avoidance of serious impairment of the efficiency, by giving attention to the securing of low coefficients of loss in the runner and draft tube, and by observing the relations between the velocities deduced above.

Possibilities of Further Increase in Specific Speed

To get some idea of the possibilities of further increases of specific speed, it may be pointed out that if the best relation between the velocities is adhered to the losses here considered will vary as the four-thirds power of the specific speed N_{sQ}, the functional relation between efficiency and N_{sQ} being derived in the following manner:

$$h_L = \frac{f_2 f_3}{f_2 + f_3} U^2 + (f_2 + f_3) C^2_m; \text{ and from } \frac{C_m}{U} = \sqrt{\frac{\frac{f_2 f_3}{2}}{f_2 + f_3}}.$$

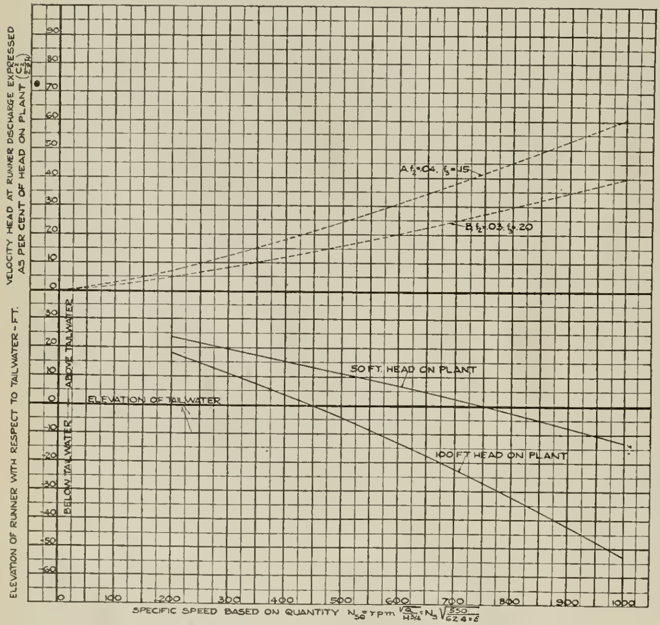

Fig. 14 Curve Showing Restriction Placed upon Specific Speed by Location of Turbine with Respect to Tailwater

$$h_L = 3(f_2 + f_3)C^2_m; \text{ and also, from } k_{sQ}N_{sQ} = U\sqrt{C_m} = \sqrt{\frac{f_2 + f_3}{\frac{f_2 f_3}{2}}}\, C_m^{3/2}$$

$$h_L = \frac{3}{2^{2/3}} \times \frac{(f_2 f_3)^{2/3}}{(f_2 + f_3)^{1/3}} k^{4/3}_{sQ} N^{4/3}_{sQ}, \text{ and}$$

$$\text{efficiency} = 1 - \frac{3}{2^{2/3}} \times \frac{(f_2 f_3)^{2/3}}{(f_2 + f_3)^{1/3}} k^{4/3}_{sQ} N^{4/3}_{sQ}$$

This considers the effect of only the two losses here treated of, and neglects certain other losses. These values of efficiency are therefore merely indications of the limiting values attainable.

The two losses mentioned account for nearly the whole loss in turbines of high specific speed. In low-speed machines two other losses assume importance—those due to leakage and disk friction. These losses can be shown to be given approximately by the following formulas:[1]

[1] For derivation see paper on The Specific Speed of Hydraulic Turbines by the writer, presented at December 28–30, 1908, meeting of Am. Assn. for Advancement of Science, and printed in *The Polytechnic* of Rensselaer Poly. Inst., 1913.

Leakage loss, expressed as a fraction of the total quantity, is equal to

$$L_L = \frac{q_L}{Q} = \frac{201\,\phi^2}{N^2_{sQ}}$$

where ϕ has the usual significance; i. e.,

$$\phi = \frac{\pi D N}{60\sqrt{2gH}}$$

and disk-friction loss, expressed as a fraction of the total power, is equal to

$$L_D = \frac{l_d}{\text{hp.}} = \frac{35\,\phi^5}{N^2_s}$$

and for present purposes a still rougher approximation will be sufficient, giving

$$L_L = \frac{100}{N^2_{sQ}} \text{ and } L_D = \frac{6}{N^2_s}$$

When labyrinth seals are used for the runner, the above leakage loss, which is for ordinary seals, may be as roughly equal to $L_L = 50/N^2_{sQ}$ or even less. We shall find that these losses become negligible at moderate values of N_s and N_{sQ} and are of no importance in the high-speed field which we are particularly investigating.

Turbine and Pump Efficiencies as Related to Specific Speed

In Fig. 13 are shown a series of curves of efficiency plotted against N_{sQ}. Curve A is the attainable efficiency computed from the theoretic relation derived above, using as values of the coefficients $f_2 = 0.04$ and $f_3 = 0.15$. To show the effect of altering the coefficients, Curve B has been plotted with $f_2 = 0.03$; $f_3 = 0.20$. The effect of leakage and disk friction has been shown by deducting these losses from the efficiencies given by Curve A, and Curve C shows the result (the leakage loss being figured for turbines having labyrinth seals).

To show the general progress which has been made in recent years, and the continuing trend toward higher specific speeds, a number of other curves have been plotted in the same figure, four of them being for pumps.

It is interesting to note the similarity in the form of Curves G and H with A and B. As more development work is carried out in the high-specific-speed field, it may be expected that the efficiencies shown by Curves F and Q, for both turbines and pumps, will be materially exceeded and brought in closer relation to the theoretic values of Curves A and B, assuming that the coefficients used in computing these curves can be more closely approached.

The generally lower range of values of pumps as compared to turbines at all specific speeds is not entirely due to essential differences in action, but much of the difference the writer believes to be attributable to the generally smaller dimensions of pumps; although the pump suffers a definite disadvantage in its action from the fact that in the pump the impeller imparts velocity head to the fluid and depends upon a stationary diffuser for the reconversion of this velocity head into pressure head; while in the turbine pressure head is converted into velocity head in the stationary casing and guides, and is absorbed in the runner, leaving only a small portion for reconversion in the draft tube.

Going back to the theoretic conditions for best efficiency or higher specific speed, let us see what is involved in the increases in specific speed shown by Curves A and B. These high specific speeds are imagined to be attained without changing the proportioning of the velocities relatively to each other, but by increasing the magnitudes of all of them, and thus requiring the use of higher velocity heads in comparison with the head on the plant. To see what this means in actual values, we can determine the manner in which the absolute velocity of discharge from the runner

$$\frac{C_m}{C} = \frac{\sqrt{\frac{f_2 f_3}{2}}}{\sqrt{f_2^2 + \frac{f_2 f_3}{2}}}; \quad \frac{U}{C} = \frac{f_2 + f_3}{\sqrt{f_2^2 + \frac{f_2 f_3}{2}}}$$

We also have

$$k_{sQ} N_{sQ} = U\sqrt{C_m} = \frac{(f_2 + f_3)\left(\frac{f_2 f_3}{2}\right)^{1/4}}{\left(f_2^2 + \frac{f_2 f_3}{2}\right)^{3/4}} C^{3/2}$$

and hence

$$C^2 = \frac{f_2^2 + \frac{f_2 + f_3}{2}}{(f_2 + f_3)^{4/3}\left(\frac{f_2 f_3}{2}\right)^{1/3}} k_{sQ}^{4/3} N_{sQ}^{4/3}$$

or

$$C^2 = \frac{c_2^2}{2gH} = \frac{1 + \frac{f_3}{2f_2}}{\left(1 + \frac{f_3}{f_2}\right)^{4/3}\left(\frac{f_3}{2f_2}\right)^{1/3}} k_{sQ}^{4/3} N_{sQ}^{4/3}$$

From the last equation values of C^2, which represents the ratio of the velocity head of the water at discharge from the runner to the head on the turbine, can be computed for various values of the specific speed. As previously noted, the term k_{sQ} in the formula for C^2 is a coefficient having the value

$$k_{sQ} = \frac{\pi D_2}{60\,(2g)^{3/4}\sqrt{A}}$$

In this expression D_2 should be taken as the mean diameter of discharge of the runner and A the cross-sectional area of the space into which the runner discharges, measured in a section perpendicular to the turbine axis. In a runner in which the direction of the meridian velocity of discharge is at a moderate inclination to the axis and having vanes extending nearly to the axis, D_2 may be taken as approximately equal to $^2/_3\, D$, where D is the diameter of the outflow space. This gives us

The computation has been carried out for the two sets of values of f_2 and f_3 which were used in plotting Curves A and B in Fig. 13. Fig. 14 (upper diagram) shows the corresponding values of C^2, the curves in this figure being marked A and B to correspond to Fig. 13.

The ordinates of these curves represent the velocity head corresponding to the absolute velocity of discharge from the runner, expressed as a percentage of the head on the turbine. With the low values of the coefficients f_2 and f_3 which have been used in computing these curves, the possibility is shown of developing

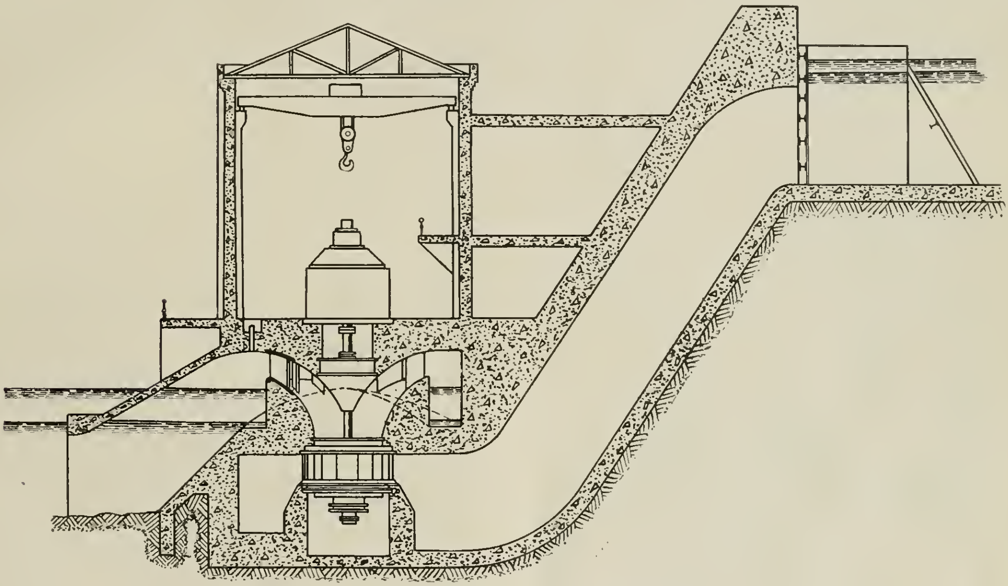

Fig. 15 New Type of Power Plant

much higher specific speeds than have yet been attained, and it is also seen that this can be done without the necessity of employing extremely high velocity heads. It may be found from later experience that somewhat higher velocity heads may be employed without serious loss in efficiency, in order to reduce the turbine dimensions. The exact numerical values of coefficients f_2 and f_3 which can be secured in the future remain for further investigation to show.

Whatever the values of the coefficients secured by a particular turbine design the relation indicated by the general form of the curves of the last figure will always apply, i. e., increases in specific speed to extremely high values will inevitably involve, sooner or later, the use of higher velocity heads at the runner discharge. In turbines arranged according to present practice the extent to which the increase in specific speed can be carried will be limited by the height of the turbine runner above the surface of the tailwater.

In order that the absolute pressure at the runner discharge should be kept at a sufficient margin above the point at which the water will vaporize, and to provide the necessary head for the retardation of flow during quick gate closures, the sum of the static elevation of the runner above the tailwater surface and the regained velocity head should not approach unduly close to the barometric limit of 34 ft., and in the following examples the limit will be set at 27 ft. With such a limiting value, if a runner should be placed, say, 17 ft. above tailwater, there would remain only 10 ft. as the limit of the velocity head which can be employed, making the necessary allowance, however, for draft-tube losses,

distribution of velocity, and increase in velocity during full-gate operation.

In order to show in a general way the restriction placed upon specific speed by the location of the turbine with respect to tailwater, the curves shown in the lower part of Fig. 14 have been drawn, using Curve A in the upper portion of this figure as a basis, but adding 30 per cent to the velocity heads called for by this curve in order to provide a margin to cover certain factors, including the unequal distribution of velocities at the runner discharge and the variation in the absolute velocity from the normal point of operation up to full gate, the necessary margin being reduced, however, by the fact that velocity head is not completely regained by the draft tube. Two curves are shown in the figure, for plants operating respectively under heads of 50 ft. and 100 ft.

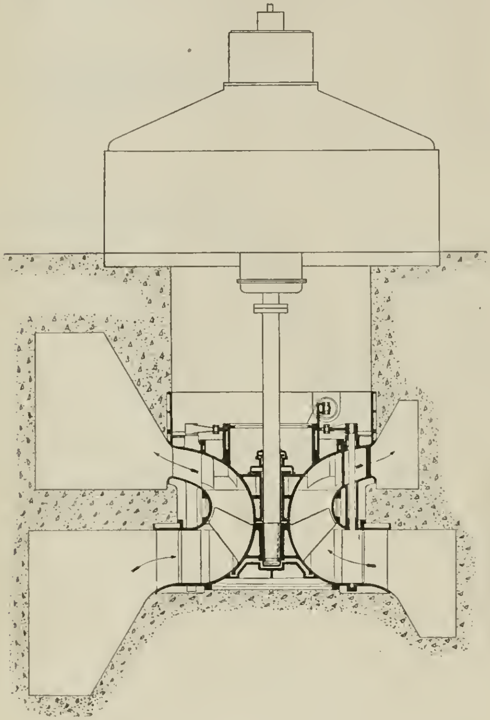

Fig. 16 Inverted Turbine of the Wicket-Gate Type

It will be noted that even with the low outflow losses called for by the types of turbine considered, a point is soon reached where the turbine must be set at the tailwater elevation or below it. If the turbine should be applied to heads higher than 100 ft., this point would occur at still lower specific speeds.

Power Plants with Inverted Turbines and Draft Tubes Directed Upward from Runners

If we should adhere to the usual practice in the design of power plants, the future extension of the available range of specific speeds for turbines would be narrowly restricted. The following procedure has, however, been proposed by Mr. H. Birchard Taylor, namely, that we remove this restriction on future progress and abandon the universal practice of placing the turbine runner at a considerable height above tailwater. Mr. Taylor proposes, if necessary, to locate the runner considerably below the normal tailwater elevation. The objection immediately presents itself that even if the runner is placed above normal tailwater it will be submerged and inaccessible during times of high water. This difficulty is overcome by the very simple but somewhat radical procedure of turning the turbine upside down and directing the draft tube upward from the runner, so that it will discharge over a crest located slightly above the highest tailwater elevation to be encountered in a particular installation. Fig. 15 shows a power plant built in accordance with this idea, and Figs. 16 and 17 two new forms of inverted-type turbine which could be used in such a plant.

In Fig. 15 the turbine is arranged with wicket gates or movable guide vanes, operating from below in a pit provided for the purpose. The draft tube is of the spreading type, the outer barrel of the tube being used to form a circular crest to exclude the tailwater when access is desired to the interior of the turbine. The procedure to follow would be to close the head gates and to pump out the water contained by the draft tube and turbine passages by the use of low-head centrifugal pumps or hydraulic ejectors.

Without going into all of the new features opened by this arrangement, it may be mentioned that the turbine casing, which is under a considerable amount of pressure, is located at a low point in the power-house substructure where there is a large mass of concrete above it to counteract the upward pressure of the water. An excellent design of draft tube can be used without requiring any increased depth of excavation, and the runner is naturally located at a low point in the substructure.

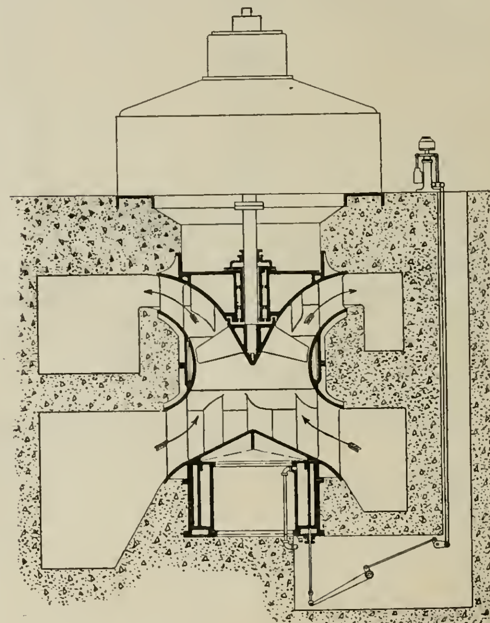

Fig. 17 Inverted Turbine of the Plunger-Gate Type

The arrangements shown in Figs. 16 and 17 can be readily understood from the drawings. In the turbine in Fig. 16 wicket gates are used with the guide-vane stems carried up through, or in line with, the draft-tube stay vanes which are used to support the superimposed structure, and "outside" operating mechanism is used, arranged in the usual manner in the turbine pit. In Fig. 17 a plunger gate is used instead of the usual wicket gates, this plunger being operated by hydraulic pressure.

In conclusion, the writer hopes that in pointing out some of the possibilities for the future development of the turbine, and some of the factors affecting its evolution, the suggestions presented in the foregoing pages may prove helpful to other engineers working in this field.

Speed Regulation of the Hydraulic Turbine

By RAYMOND D. JOHNSON,[1] NEW YORK, N. Y.

THERE is a more or less prevalent idea that the water-wheel governor, of itself, directly controls the speed of the units. The only direct function of a governor, however, is to alter the wheel-gate opening when impelled to do so by a slight change in the speed. It is also endued with more or less independent or secondary functions which check its natural motion and which introduce delay after the first impulse has become effectual.

These secondary adjustments may succeed in producing good speed regulation or they may not, regardless of the perfection of the governor itself and dependent entirely upon the thought which has been put into the general layout of the plant.

For example, consider a case of a long pipe line where the velocities are allowed to run too high in proportion to the head on the plant; any additional draft or water will of course lower the pressure at the power house, due to friction, and will therefore produce less power so far as the head is concerned, while at the same time it is producing more power from the additional amount of water. It may seem a fanciful thing that a condition could ever arise where the proportionate drop in head ould offset, in power, the extra amount of water supplied, but it is so far from being fanciful that it has actually occurred in plants, in the region of gate openings between three-quarters and full. In fact, it occurs more often than is commonly supposed and it is a condition which is not always discovered by the operators. It is clear that the governor would have absolutely no control of the speed of the turbine under this extreme condition. A slight increment of load would drop the speed and impel the governor to open the gates wider without recovering any of the loss of speed but, nevertheless, causing a great waste of water to no purpose.

It may appear that such a condition is the result of such gross incompetence in design as to make it of little interest to real engineers, but this is not the case, because coöperation of the water-wheel characteristics and surges in pressure, due to increments of load, with insufficient area of the feeder pipe, may easily produce such results, even when the general features of the plant are arranged in more or less standard fashion. or example, suppose that the pipe line is more or less adequate, not nearly approaching the extreme condition as above mentioned, so that when additional water is called for there is a very decided increase in the power, in spite of the drop in hydraulic gradient; but, at the same time let us assume that the water wheel has been opened beyond its point of best efficiency, toward full gate, and that in so doing it has suffered a material loss in efficiency due to its drooping characteristic. In such a case the further opening of the wheel gates may cause to be delivered to the generator no more power than it received prior to the action of the governor. This may strike some as a hair-splitting contention, but it will be found, upon a brief investigation with actual figures, that the atter is a very important one.

Now let us suppose that both of these terms have been adequately considered and properly taken care of and that, nevertheless, the same trouble arises. This may be due to a drop in pressure caused by surging. In other words, even though the drop in pressure, due to the change of hydraulic gradient, is not sufficient to produce a permanent condition of impossible governing, yet the short duration drop in pressure, due to inertia of the water column as modified by a surge tank, may add to the trouble sufficiently to bring about the same difficulty.

It is also well to remember that these conditions do not have to exist in an extreme degree to render the speed regulation very unsatisfactory, but an approach to them may almost discount the efforts of the governor.

[1] Consulting Engineer, Mem.Am.Soc. M.E.

Abstract of a paper presented at the Symposium on Hydroelectric Development and Distribution, held at Philadelphia, January 21, 1921, under the auspices of the Engineers' Club of Philadelphia and the Philadelphia Sections of the American Society of Civil Engineers, the American Institute of Electrical Engineers and The American Society of Mechanical Engineers.

It is well known that the ordinary characteristic of the Francis turbine is such as to give a maximum efficiency at part gate and the manufacturers all show drooping curves beyond this point, up to full gate. The water wheel is ordinarily rated at its full-gate power.

Now, unless one has carefully studied the relation of the additional power to the additional water on the drooping part of this curve, it is fairly safe to say that he has little realization of exactly what this means.

A good way to study it is to plot a first differential curve showing the relation of added water to added power and to express the efficiency as such. In this way it will often appear that whereas the full-gate efficiency may be given as perhaps 88 per cent, the actual efficiency of small increments of water, compared to the corresponding increments of power, may go as low as 25 or 30 per cent near full gate.

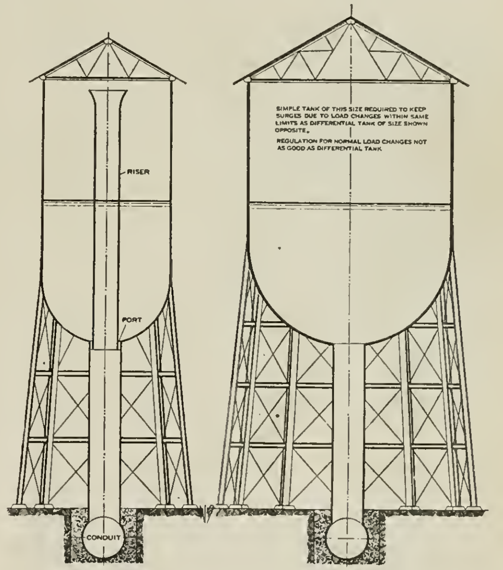

FIG. 1 RELATIVE PROPORTIONS OF SIMPLE AND DIFFERENTIAL SURGE TANKS

his stealing of additional water might not be of any great importance in an open-flume setting, but at the end of a long pipe line this additional water causes more surging, more friction drop, with little or no increase of actual power; and it is the writer's firm belief that in all such cases the turbines should be rated as at their full power output where the efficiency is only slightly less than the maximum and the motion of the water-wheel gates should be limited in an unchangeable way so that they cannot be opened beyond this point. This conclusion has been reached as the result of the study of many designs where long pipe lines and surge tanks have been used.

The flywheel effect of the rotating parts is an important factor in regulation, and the ability to store energy in this way as the speed slightly rises and to release energy as the speed falls off, furnishes a time element in which the flow of water in the penstock may be partially or completely readjusted to the new demand of the load. It is the writer's belief that even this well-known feature has not always received sufficient attention and that the regulation of many plants could be materially improved by the addition of heavy steel flywheels.

It is the present purpose, however, to dwell more particularly

upon the function of the surge tank, the correct design of which is probably the most potent factor in promoting proper regulation.

The function of a properly designed surge tank is complex. It may be said to have six distinct duties:

1 To regulate the pressure, preventing undue rise or fall following sudden motion of the water-wheel gates
2 To act as a reservoir furnishing water promptly to the wheel when a sudden demand is made for more, thus taking care of the time element in which the water in the long conduit may be accelerated
3 To lengthen the period of oscillation of a surge so that the governor may prove fast enough to follow it with the gate motion in order to keep the power output of the unit at constant value
4 To damp out this surge vibration in spite of the augmenting effect of the governor action, so that the variation of pressure will not continue to increase after having once been started in oscillation

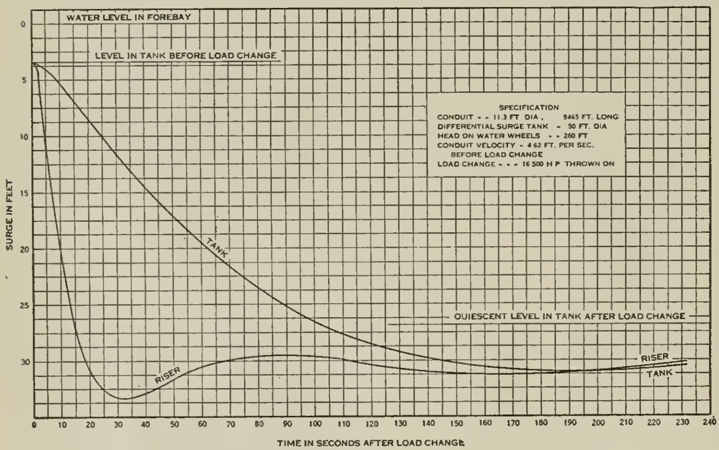

FIG. 2 TYPICAL VARIATION OF WATER LEVEL IN BOTH TANK AND STANDPIPE OF A DIFFERENTIAL REGULATOR

5 To furnish sufficient internal resistance to accomplish this damping effect without depending upon excessive friction in the water system itself which would also assist in this duty
6 To conserve water which would otherwise be wasted in overflow or through a by-pass.

An ordinary standpipe of somewhat large dimensions is frequently designated as a simple surge tank. Its action may be likened to one leg of a U-tube filled with fluid; that is to say, the forebay and pipe-line system, together with the surge tank, form a hydraulic pendulum in which an oscillation when once started by a change of load tends to maintain itself indefinitely, as a pendulum, until the action of friction stops it.

It is plain to be seen that the worse the design of the plant and the more the power which is thrown away in friction, the less likelihood there is of troublesome conditions due to oscillation.

When the waterways are comparatively free from friction, a simple surge tank, such as above described, designed to operate properly, will have to be very large and expensive. This is due principally to the fact that the operation of the governor is such as to keep alive any oscillation which is once initiated.

That is to say, as the water level is dropping due to a load demand, the head is also falling off and the wheel gates must continue to open wider and wider in order to maintain a constant power output of the unit. This calls for more and more water as the level drops and very materially increases the magnitude of the surge; and conversely, as the water rises, the wheel gates must continually decrease their opening for the same reason, and thus fan the surge wave into lively activity.

In other words, the simple surge tank is not, properly speaking, a regulator at all, because it depends upon an undesirable and unnecessary amount of friction to make it work right.

It is of course, a fact that some plants are operating under such conditions and oftentimes without a suspicion on the part of those associated with them that any material improvement would be possible; but a close scrutiny of many of them shows that were it not for almost inexcusably large losses of head, the surge tank, as installed, would not only *not* be a benefit, but would even prove to be a source of danger.

To obviate this difficulty and to provide a regulator which will permit the utmost smoothness of all the waterways, the differential surge tank (see Fig. 1) has been devised. This is really a double tank—the smaller one in the nature of a standpipe freely connected to the conduit and surrounded by another tank which is connected to the conduit by means of a restricted passage. The action of the internal standpipe is very much the same as that of the ordinary standpipe, except that as the water tends to rise or fall its motion is checked by secondary escape of water through the restricted passage into or out of the larger tank. This produces a differential, nonperiodic action which is absolutely effective in steadying down any tendency toward instability of the surge wave; and furthermore, inasmuch as the motion of the water within the smaller pipe is relatively rapid as compared to what it would be in a larger simple surge tank, an accelerating head is rapidly applied to the conduit and less water has to be supplied or received than in the case of a simple tank of corresponding dimensions.

Fig. 1 illustrates the relative sizes of simple and differential surge tanks for a given case. In general it may be said that the ratio of the two sectional areas will vary from about two to nearly four, depending upon the physical conditions to be met.

Fig. 2 illustrates the typical variation of water level in both the tank and standpipe (or riser) of a differential regulator. The comparatively sudden drop in the riser level starts immediately an active acceleration of the water column leading from the forebay and, meantime, the lack of water which is only gradually provided through the conduit, is supplied by the tank, thus producing the upper curve.

In about 190 seconds, as shown by the diagram, these two levels come together, which indicates that at that time the conduit velocity has received sufficient acceleration to supply the new demand for water and no further depression of level takes place.

The water level will eventually become quiescent with no further load change, at the elevation shown on the diagram, and if one considers the small distance between this level and the point where the curves cross as compared to the distance up to the level before the load change, it will become apparent how little life is left in this wave.

In other words, the level in this case has not dropped a great deal below the point where the end of the new hydraulic gradient would, in any event, require it to go.

If it should seem desirable to have these two curves cross exactly at the final quiescent level, this could easily be done by making the regulator slightly larger, in which case there would be no surging whatever. That is to say, there would be no motion in the water greater than that which is inevitable on account of the fact that the larger draft of water requires a greater drop in the hydraulic gradient.

This absolute damping of deadbeat effect can also be obtained by means of a simple surge tank, but in that case the area has to be nearly four times as great.

(*Continued on page 248*)

Measuring Water Flow for Power Purposes

Description of a New Method and Its Application in the Efficiency Tests of the 37,500-Hp. Turbines of the Niagara Falls Power Company

By N. R. Gibson,[1] Niagara Falls, N. Y.

The necessity of measuring the flow of water used for power purposes at Niagara Falls is known to all who are familiar with conditions there, but many others would imagine that with the whole Niagara River to draw from the consumption of water would be the last thing to consider. On account of the restrictions placed by law upon the diversion of water for power purposes from the Niagara River, however, the measurement of the quantity of water used in the various power plants is a matter of extreme importance. According to the terms of a treaty between the United States and Great Britain, each country is permitted to divert for power purposes a certain quantity of water. In the United States this quantity is 20,000 cu. ft. per sec. and the Niagara Falls Power Company's allotment is 19,500 cu. ft. per sec. The terms of this treaty are being rigorously observed, and in the observance the output in kilowatts of the power company's plants must not at any time exceed the capacity which will utilize its allotted quantity of water.

To determine the relation between power and discharge of a unit it becomes necessary, therefore, to measure the quantity of water used and incidentally to determine the efficiency of the turbine. The importance of this measurement and the accuracy desired will be appreciated if the annual value of the power that can be produced from one per cent of the water allotment is computed. One per cent of 19,500 cu. ft. per sec. would generate in the existing plants at least 4000 hp., the income from which may be placed at about $80,000 per year. On the one hand, therefore, if the allowed capacity were one per cent less than the correct value, the company would be deprived of the possibility of earning about $80,000 per year, and on the other hand if the allowed capacity were one per cent greater than the correct value, it would be able to receive revenue in the same amount in excess of that to which it was legally entitled. The burden of proof, of course, is placed on the power company, and rightly so.

When the three new 37,500-hp. turbines were installed and ready for operation the company was then in a position to use all the water to which it was entitled and the regulating authorities fixed the efficiencies of the new units at a point which it was believed would not be greater than the actual efficiencies. Possibly the efficiency was fixed low enough to make it worth while for the company to go to the expense of proving the exact e ciency. In any event the results were not disappointing because after making the official tests, which received the approval of the division engineer, the allowable output from the three units when charged with the same quantity of water as formerly was increased by nearly 5000 hp.

Shortly before these units were installed the writer had invented a new method of flow measurement which seemed to offer many advantages, particularly in the case of very large units supplied with water through closed conduits. This method was the outcome of studies of the c anges of pressure in penstocks caused by the gradual closing of turbine gates which appeared in the form of a paper in the Proceedings of the American Society of Civil Engineers in April 1919. The company is fortunate in having in Mr. John L. Harper a chief engineer of broad vision and unlimited courage, so when the new method of measurement was proposed to him it received at once his full support, and the writer was given an opportunity to develop the method and apparatus for its application.

The method makes use of two well-known principles, the first being Newton's second law of motion, sometimes referred to as the equation of impulse momentum, and the second being a corollary of the first, namely, the relation between change of pressure and change of velocity of a column of water expressed in terms of the velocity of the pressure wave. The application of these two principles makes it possible to determine the mean velocity of a column of water in a penstock by recording the changes of pressure at a point in the pipe line when the flow of water therein is gradually brought to rest by closing a valve or the turbine gates. The mean change of pressure so recorded is a precise measure of the velocity destroyed.

In practical work it is not always possible to stop the flow entirely, because leakage nearly always occurs through the turbine

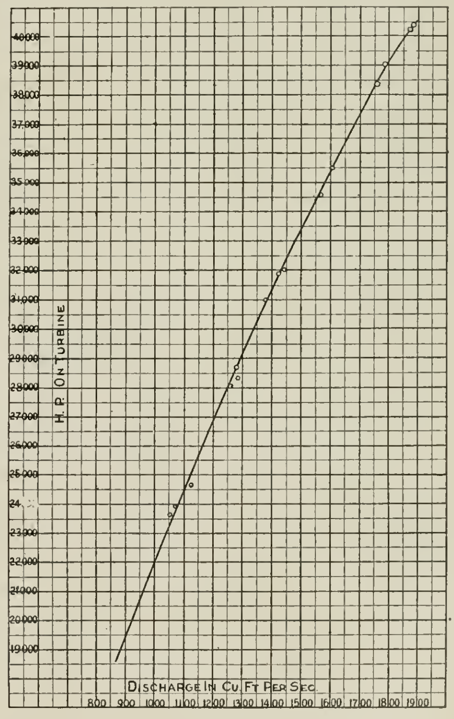

Fig. 1 Power-Discharge Curve for Unit No. 18 of the Niagara Falls Power Company

gates, and in such cases the velocity determined is the difference between the initial and final velocities. The remainder is readily determined in one of several ways.

The apparatus employed comprises a new combination of simple elemental parts in which the pressure element is a U-tube containing mercury, the motion of which can be made to correspond in any desired ratio to the change of pressure in the penstock. The apparatus provides illumination and records photographically to exact full scale the motion of the top surface of the mercury in the tube and combines in the record the oscillations of a seconds pendulum. The resulting diagram shows to exact scale a complete record of pressure changes and time.

After completing the theoretical studies and after building the

[1] Hydraulic Engineer, Niagara Falls Power Company.

Abstract of a paper presented at the Symposium on Hydroelectric Development and Distribution, held at Philadelphia, January 21, 1921, under the auspices of the Engineers' Club of Philadelphia and the Philadelphia Sections of the American Society of Civil Engineers, the American Institute of Electrical Engineers, and The American Society of Mechanical Engineers.

first apparatus, which has subsequently been much improved, both theory and apparatus were tested by experiments.

One of the most important reasons why it was desired to use the new method rather than one of the older and well-known methods, was that tests could be carried out without serious or prolonged interruption of the supply of power from the unit being tested. It requires a two-minute shutdown for each measurement, and the measurements may be repeated about once every ten or fifteen minutes. A complete set of measurements at each tenth gate opening from half to full gate may be made in less than two hours, and during that time the unit would be out of commercial service only about fifteen minutes.

There were two other reasons that may be mentioned, one being that the trouble and expense of the tests would be much less than by any other method, and the other that it was believed the new method was very accurate.

Without going too deeply into theory, the reason for the accuracy of the new method will be appreciated by a reference to the fact that a small change in velocity can be made to produce a relatively large change of pressure. The mean change of pressure corresponding to a change of velocity can be made from five to twenty times the velocity head or even greater if there were any advantage in doing so. In the pitot tube the velocity head only is observed, or, at best, by differential methods only some small multiple of it. In the new method a record is made with great precision of a quantity that is many times greater than the velocity head. In other words, the quantity observed and recorded is many times greater than, but is proportional to, the quantity it is desired to know. It is true, of course, that this change of pressure takes place in a comparatively short time, and the element of time must be considered. It is comparatively easy, however, to measure time very accurately. If an interval of ten seconds is measured within one-tenth of a second, the error is only one per cent, but time may be quite readily measured within one one-hundredth of a second, in which case the error is only one-tenth of one per cent. It so happens, however, that in the new method it is not necessary to measure time directly at all, but only the product of pressure and time, which may be done very accurately indeed.

In order to obtain satisfactory proof of the accuracy of the new method of measurement, as required by the authorities in charge of the regulation of the use of the water, arrangements were made with Dean E. E. Haskell, of the College of Civil Engineering at Cornell University, to have a thorough test made by comparison with volumetric measurement at the laboratory of the university. Six series of tests were made under conditions approximating as nearly as could be had at the laboratory, the conditions prevailing for efficiency tests at Niagara Falls. Table 1 shows the results of the nineteen tests made, from which it is seen that the average of all measurements made by the Gibson method agrees within less than two-tenths of one per cent with the average of all the volumetric measurements. The maximum variation of any one series is eight-tenths of one per cent.

A very careful analysis of these results has been made, which indicates that part of even the slight variations between the volumetric measurements and measurements by the new method may be explained by a very slight unsteadiness of flow, which is sufficient to account for some of the difference between the two measurements. This unsteadiness seems to be characteristic of all water flowing above the critical velocity, and while difficult to account for, it was manifest in this case by the variations in the level of the water passing over the weir before it entered the measuring tank. The magnitude of the variations in gage height was an index of the magnitude of the variations in flow. It would be natural of course that variations in the measurements due to this cause would be both positive and negative, and the mean of a series of results would not show differences of the same magnitude as might occasionally be found in any single measurement. The fact that the mean variation between the volumetric measurements and the measurements by the new method is only two-tenths of one per cent would indicate that, while there might be a difference between the two methods of measurement for any one observation, each method might be as near perfect as the other, because the quantity measured is slightly different in each case.

Having thus established, by careful experiments, the accuracy of the new method, the official efficiency tests of the before-mentioned three new units in Station No. 3 Extension were made on June 29, August 8, and August 17, respectively. On account of the ease with which diagrams can be made, several were taken at each gate opening so as to obtain an average result, and in all from sixteen to eighteen diagrams were made for each unit.

After velocities had been calculated from the diagrams and discharges, and effective heads computed, the usual power-discharge and efficiency curves were prepared. Fig. 1, which is representative, shows the remarkable uniformity in the determination of the points along the power-discharge curves, from which it may be concluded that the errors of observation, or so-called variable errors, are extremely small. The absence of any inherent or consistent error was demonstrated by the tests made at Cornell University.

TABLE 1 COMPARISON OF VOLUMETRIC MEASUREMENTS WITH THOSE MADE BY AUTHOR'S METHOD

Date 1920	—Discharge— (cu. ft. per sec.) Volumetric	Gibson	Per cent variation	Remarks
June 11	20.27	20.31	+0.2	Tube R = 1.335.
June 11	20.42	20.52	+0.5	
June 11	20.45	20.65	+0.9	
	20.38	20.48	+0.5	Mean of series.
May 24	30.38	30.51	+0.4	
May 25	30.63	....	...	Poor diagram (not completed)
May 25	30.69	31.15	+1.5	
	30.57	30.82	+0.8	Mean of series.
May 25	42.24	42.17	−0.2	
May 25	41.94	42.28	+0.8	
May 25	42.22	42.09	−0.3	
May 25	....	41.96	...	Volumetric not taken.
	42.13	42.12	0.0	Mean of series.
June 4	40.36	40.41	+0.1	
June 4	40.36	40.90	+1.3	
June 5	40.98	40.88	−0.2	
	40.57	40.73	+0.4	Mean of series.
May 29	46.82	....	...	Film fogged, diagram invisible
May 29	46.95	46.60	−0.7	
May 29	46.98	46.60	−0.8	
	46.92	46.60	−0.7	Mean of series.
June 7	50.30	49.95	−0.7	
June 9	50.66	51.47	+1.6	
June 10	50.93	51.15	+0.4	
	50.63	50.85	+0.4	Mean of series.
Total of Means	231.20	231.60	+0.2	Mean variation of all tests.

In conclusion, attention may be drawn to some of the advantages of the new method of measurement where it may be applied:

1 Remarkable accuracy in the determination of the velocity of flow because small changes of velocity result in comparatively large changes in the pressure to be recorded.

2 Determination of velocity may be made without serious or prolonged interruption of the commercial supply of power from the unit being tested.

3 Each determination of the velocity of flow may be made quickly in one operation, tedious methods involving tabulation of observed results being avoided.

4 The process is essentially simple and inexpensive. Special appurtenances in the pipe line are not required.

SPEED REGULATION OF TURBINES

(Continued from page 246)

Where large tanks have to be supported on towers, if the differential action is not resorted to, the dimensions of a simple tank will be such as to make its construction impossible on account of exceeding the limits of the boilermaker's art in respect to thickness of plate, size of rivets, etc., where most of the assembling must be done in the field.

Merely because a water-power plant is in successful commercial operation, is by no means an indication that it is doing nearly its best. It seems rather remarkable that while great attention is usually paid to the question of high efficiency of the water wheels and generators and much effort is expended to gain the last one-half of one per cent, enormously larger losses are sometimes permitted to accumulate in the water system, which, by reason of their not having been definitely located or computed, never cause the slightest concern to the financial interests.

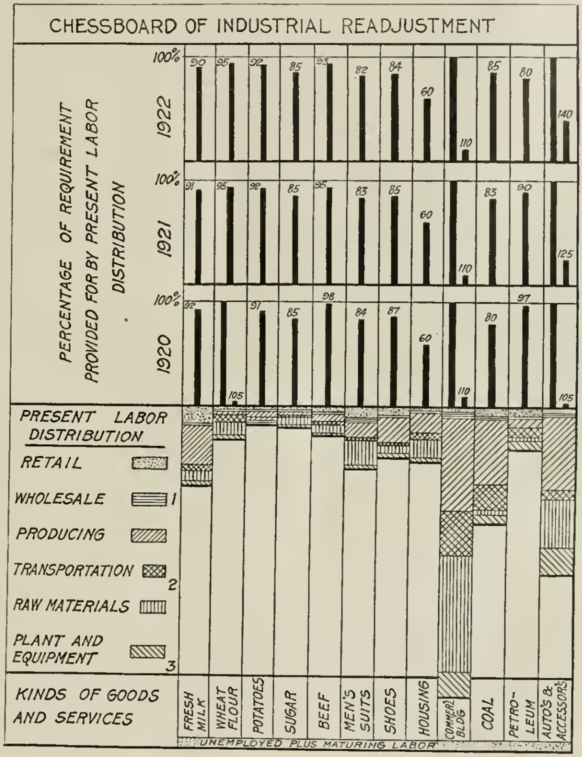
the past and upon *beliefs* formed by frequent repetition of dogmas; and inasmuch as conservatism is an element of dogmatism, it is therefore of necessity arrogant. Its method of self-preservation is to prevent the verification of truth by experiment with facts. Wars and revolutions do not happen—they are caused by arrogance of conservatism based on insufficient knowledge of the laws governing human development.

Self-assumed authority and unanimity, upon which human relations are formulated (commonly known as autocracy and democracy) are conservative in so far as they are based upon beliefs accepted in the past. Their preservation depends upon legal opinion and police force. Opinion derived from an accepted dogma (through scholastic speculation) is impotent to discover new truths, while the power of police force is exercised to suppress their manifestations.

As opposed to this *static* character of social relations, there is produced the *dynamic* force of the economic, intellectual, and spiritual relation through the accumulation of a mass of positive knowledge which gains momentum through a period of time. The gap between the two has been increasing at an accelerated rate until now the old social relations are collapsing and new dogmas are being formulated corresponding more closely with the existing state of technique. Thus in social relations we observe revolution, while in economic and spiritual we have evolution.

The conflict of static control and dynamic process is peculiar only to human life. Prehistoric bees and ants performed their work in a manner identical with ants and bees of today. No expert bee taught posterity how to produce more honey in less time; no expert ant trained the rest of them how to build hills quicker and with less exertion.

On the other hand, the "binding time capacity of the human class of life" has been an unconscious force working toward progress and improvement. Its impulse has been to seek, to learn and to teach how to produce greater results in less time, thus saving the time allotted us to live. The fundamental law of the human class of life is binding time, the natural expression of which



Example of Use of Gantt's Method in Analyzing Industrial Readjustment

[1] Consulting Engineer, Walter N. Polakov & Co., Inc., Mem. Am.Soc.M.E. Paper presented at the Annual Meeting, New York, December 1920, of The American Society of Mechanical Engineers. All papers are subject to revision.

as an expression of the human law of "binding time." This capacity of humans to "bind time" and thereby to accumulate a wealth of knowledge, like any natural organic capacity is insuppressible, as has been demonstrated for the first time by A. Korzybski in his forthcoming book Human Engineering. The suppression or interference with the exercise of this potential power creates counteraction, with consequences as disastrous as an interference with any other known law of nature.

The Philosophy of H. L. Gantt

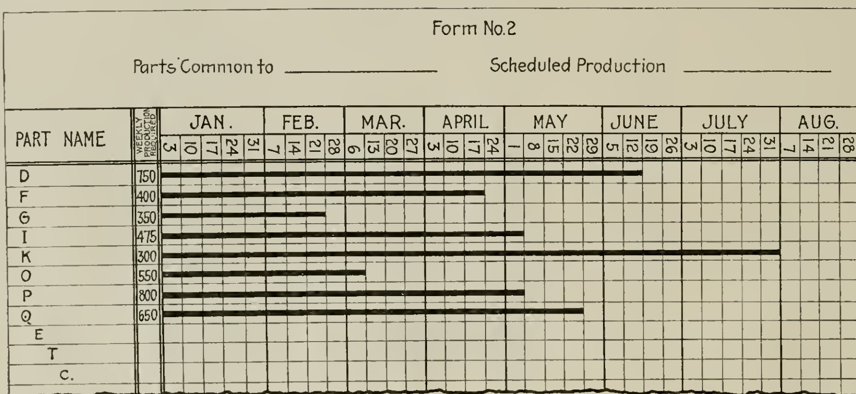
Gantt's philosophy was formulated with an understanding of this first law of human life and can neither be disputed nor ignored. Its application to human relations, and more specifically to industrial problems, is as inevitable as the application of the law of gravitation to astronomy with certainty in foreseeing the results. The method of application of this philosophic concept to the solution of practical problems determines what these results are to be in the same manner as in the solution of a mathematical problem, where an error in the answer is not due to any fallacy in the principles themselves but rather to the method of application of the principles. As formulated by Gantt, the "business system had its foundation in service, and as far as the community is concerned, has no reason for existence except the service it can render."

The foundation of our economic, industrial, and business system lies in the service rendered by all the preceding generations of humanity. A sewing machine is capable of increasing the productivity of its operator not only by the amount of labor worked into it by the mechanic who made it, but by the integrated services of all the scientists, philosophers, artisans, etc., and of all those who since the ages of primitive men have served indirectly to make their lives and works possible. If this were not so, the increased productivity of an operator using a machine would be equal only to the productive efforts expended in its construction. The law of Mayer and Lavoisier, that energy and matter cannot be created or annihilated, would receive its death blow by the first yard of stitches made on the machine in excess of the energy expended by all the living coöperating workers.

The law of nature remains inviolated, however, for the "time-saving" capacity of machines is the manifestation of the service of dead men, who passed to us their ideas and knowledge. This ever-increasing accumulation of our material and spiritual wealth

is therefore not so much the fruit of our toil as that of preceding humanity. Wealth, therefore, like knowledge, if treated as personal property, loses its human value, for possession is an animal standard which is based on "binding space"—brute force of dogmatism—and not on the human capacity of "binding time."

The neglect to abide by and to live up to this natural law of humanity was in Gantt's mind when he said: "The production of goods was always secondary to the securing of dollars." This is evident from a study of our economic development which is characterized by periodic crises, that is, business depressions, financial panics, and overproduction for profit, not for use. To use Gantt's analysis: "If we could harvest more dollars by producing fewer goods, we produced fewer goods. If it happened that we could harvest more dollars by producing more goods, we made an attempt to produce more goods. To be sure, the relation between the demand for, and supply of, the product, directed by a desire to get the greatest possible profit, has resulted in a sort of control which has usually been based more on opinion than on facts, and generally exercised to secure the greatest possible profits rather than to render the greatest service." This violation of the natural law of humanity, that is, the substitution of an *animal* aim of selfish profit for the *human* aim of "binding time" by means of rendering service, brings ultimate and unescapable punishment, as does any act contrary to the laws of nature.



In "The Americas," Mr. Ellery A. Baker, of the National City Bank of New York, Adopts Gantt's Charting Mechanism, Urging Increase of Production (April 1920)

The analysis of law and fallacies brings about a realization of the consequences of violations of this law and introduces a motive into our actions. In Gantt's formulation, "The business system must accept its social responsibility and devote itself primarily to service, or the community will ultimately make the attempt to take it over to operate in its own interest." The social experiments conducted in Russia, Italy, and less systematically in Germany, England, and Austria, are ample proof that the operation of this law is as infallible, unavoidable, positive, unalterable, and universal as that of any natural law.

The conflict between the animal standards of business and the human standards of science and technology has recently culminated in the World War and subsequent revolutionary movements. The enormous power which the application of technology gives to the conservative, dogmatic rule of static animal instincts, brought about a realization of the necessity for wise direction of the dynamic forces of society. The direction of any force presupposes an understanding of laws which it follows. Until Gantt postulated the fundamental law and showed its application to be technology, this accumulated wealth of all preceding human generations remained a blind, unconscious, aimless force, beneficial or destructive as the whim of dogmatic speculation decreed.

Engineering has been variously defined according to the private opinion of scholastic minds: from the *moral* viewpoint as the "mastering of natural forces and materials for the benefit of mankind;" from the *economic* viewpoint as "engineering aims at maximum production with minimum outlay of time, efforts and resources;" or from the *utilitarian* viewpoint as "knowledge of what to do, when to do it and how to do it." Such statements demonstrate vague and arbitrary selection of aims. Now, technology, and more specifically engineering, can be defined as "a method of rendering rigorous service."

The direction of the enormous forces of technology of modern society according to static dogmas which violate the natural law of human developments, can result only in the destruction of society. Until this fundamental truth was conceived, the privilege of violating this law of humanity had its origin in ignorance. The forbidden fruit of the Tree of Knowledge was eaten before it was ripe and mankind suffered from mental indigestion until the Nazarene brought His gospel of a "chief that doth serve." For two thousand years this revelation has been dogmatized and kept out of practical application by those more willing to receive than to give service.

Using the Baconian method of induction and the Cartesian method of doubt in his confutations of economic and industrial fallacies, Gantt began with expositions of errors, proceeded with producing evidence of the causes of error, and concluded with the establishment of verified truth.

With the projection of service through time established as the natural law of humanity, the criterion for human activities suggests itself as a necessary and sufficient corollary: "In an economic or a moral sense an action is right when it will advance the cause of humanity, and wrong when it will not."[1]

Following up the mathematical method of reasoning, human relations, periodically clashing in disastrous catastrophes, present a problem consisting "in a readjustment of our economic conditions with the object of averting another such catastrophe." Such a readjustment obviously must be in compliance with the fundamental principle of human progress. The first practical task, therefore, is the exposition of error.

Gantt produced the evidence of the causes of errors from the analysis of social evils which lead the so-called civilized world periodically to such catastrophes as overproduction coincident with unemployment, epidemics, high infantile mortality, underfed school children, etc., or revolutions and wars for new markets after internal markets have been overtaxed, or competition which withholds from competitors information which would make for advancement in art. According to Gantt, industry cannot begin to fulfil its function of serving humanity until we

1 "Eliminate special privileges of whatever kind, and make industry and business serve the community;
2 Base the conduct of industry and business on facts, instead of opinions, as has been common in the past;

[1] Influence of Executives, in Annals of the American Academy of Political and Social Science, publication No. 1319.

industrial services is very close to that laid out by Francis Bacon, Lord Verulam, in his Novum Organum (1620), although his philosophy is nearer that of Descartes. He follows a well-beaten path of scientific analysis in order to eliminate and exclude all elements of doubt and to establish each fact from a sufficiently large number of observations with reasonable certainty. Gantt divides such an investigation into three parts, as follows: "An analysis of the operation into its elements; a study of these elements separately; a synthesis, or putting together the results of our study." Practice of this method leaves no room for opinions, frequently dignified by the name "theories."

Heretofore this method has been employed by every positive science and has transformed witchcraft into medicine, alchemy into chemistry, astrology into astronomy, and craftsmanship into engineering. Those lines of human endeavor that failed to adopt this scientific method remained in the medieval state of dogmatic sophistry like jurisprudence, which even in the twentieth century renders such decisions as the acquittal of a man charged with bigamy on the ground that his first wife is under legal age, hence he is not legally married to her.

This method of scientific research while in itself not new, was extended and applied by Gantt to decidedly novel purposes. It was applied to engineering rendering rigorous service to society and to the measurement of the service rendered. Heretofore profit-making managements, which aimed at converting industry into a dividend-grinding mechanism, have attempted to use scientific methods. From now on the achievement of Gantt offers a means of measuring the human or social efficiency of industry. Special privileges and incompetency are no longer a matter of private or prejudiced opinion, for by means of quantitative analysis they can be ascertained and measured with precision like any other physical phenomena. Gantt's method has made it possible to ascertain the cause of the diseased industry just as blood analysis established the cause of malaria. While the latter made the completion of the Panama Canal possible, the former will transform industry from servitude into creative service and its pensioners into respectable members of the community.

A criticism is sterile unless it carries the constructive element. The mechanism for demonstrating the results of the analysis is at once the mechanism for directing the service. The mechanism of Gantt for the analysis of service exposes error in a manner clearly indicating its cause. He who knows the cause of his failure can readily avoid failure unless he is mentally defective or criminally inclined. Graphic presentation of failures in production, distribution, etc., is as immediate in effect as it is obvious. Unlike statistical diagrams, curve records, and similar *static* forms of presenting facts of the past, charts logically evolved from the concept of "binding time" by rendering service are *kinetic*, moving, and project through time the integral elements of service rendered in the past toward the goal in the future.

Three cardinal questions asked of industry, agriculture, transportation or any other productive endeavor, are:

formity with the fundamental law of rendering service for the benefit of humanity, inasmuch as:

1 Facts being established leave no room for opinions, traditions, or fallacies
2 Facts being openly established, privilege supported by secrecy fall,
3 Facts being public, drive into disrepute incompetence, bluffs nepotism and favoritism

IDLENESS CHART

IN *The Dial* (NOV. 1, 1919) DATA OF U. S. GEOLOGICAL SURVEY, BUREAU OF MINES,, FEDERAL TRADE COMMISSION, ETC., ARE STUDIED AND REPRESENTED BY MEANS OF MR. GANTT'S METHOD

4 Results being compared, point out where most service and help is needed
5 Results attained being known, create interest in the work and bring commensurate reward
6 Attainment of the aim being recorded, stimulates rendering service.

Moreover the proper use of such mechanism points out three integral elements of the organization for rendering rigorous service, namely,

1 Reward commensurate with service rendered
2 Elimination of idleness before securing additional means of production
3 Utilization of available knowledge without awaiting the new discoveries.

The strict conformity of the above aphorisms with the fundamental postulate renders them an organic whole as irrefutable as the natural law of binding time for the human class of life.

Application and Influence of the Principles Enunciated by Gantt

The sphere of application of the principles of Gantt is limited only by the boundaries of human activities. Not every act that is performed within *time* at an expense of *energy* (whether mental or physical) falls into the class of "binding time." The applica-

tion of the criterion of projection of service through time or real "binding time" defines whether or not the act is of human dimension. An act possessing zero or negative value from the point of projecting service into future time has no human value. The inexpert waste of natural resources which is present in the consuming of time and destroying of energy through misdirected effort is contrary to the "natural law of the human class of life" because it renders a negative service to future mankind.

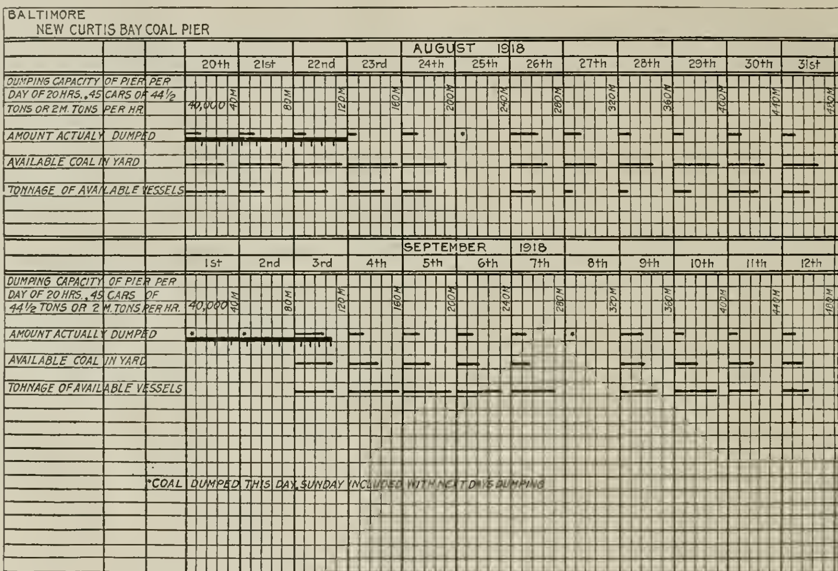
Similarly a war or other form of securing profit at the expense of destruction is a violation of the law of humanity. Again, activities that merely keep things in balance, consuming what is produced without serving futurity, as for instance those of mere maintaining animal existence, are of no human value. On the other hand, service which tends to accumulate and augment the time value, like that of increasing knowledge which will be of service in the time to come, is human and positive. A few illustrative examples of the influence of this philosophic concept and recent applications of Gantt's method to various problems are given in the five accompanying charts.

The influence of this philosophy is clearly shown in the recent conception of credit as a measure of the ability to render service (human standard) as opposed to the earlier practice of extending credit commensurate with the possession of things (animal standard), as well as in the still more recent recognition of the accountability of public utilities for their waste of natural resources.

The acceptance of the new concept is evolved in the change of our social and industrial relations from the régime of ignorant violation of the natural law of humanity for the projection of service into the future, to that of compliance with this law. Heretofore the success of an undertaking was measured in dollars. Improvements were reckoned in dollars saved. The stability of the enterprise was dependent on the steady flow of dollars. Quality of the product had value in so far as it permitted a larger margin between the price and production cost. Wages were fixed at the lowest acceptable minimum. Working hours were limited only by need for recuperation. Hygiene and safety were judged from their effect on dividends. Human relations were considered only when dollars were in danger. Natural resources were sacked, for it paid better to waste than to conserve. Outputs were determined only by the ability of the customer to buy, and not by his need. Idleness was respectable—it gave leisure to a few who could enjoy it.

The control of resources, of means of production or even of political power is of no avail whatsoever unless the productive forces are so directed and organized that the new industrial relations shall better serve large masses of people. The knowledge and the ability to do things assumes the natural, intrinsic authority and leadership. It is inevitable, therefore, that the industrial administrators, preeminently the engineers, are alone capable of mastering the complex mechanism of modern life in motion. The old masters of static things have no function in the modern dynamic society. The new leadership cannot be either autocratic or arbitrary, for dealing as it does with the laws of nature, with intrinsic laws of life, not with man-made laws of barristers, it can neither alter nor misinterpret them. Where errors spell annihilation, there is no room for opinions, whims or desires. Action must be taken on the basis of the knowledge of facts; hence those who know what to do and how to do it must assume the leadership. Their authority, being based upon the knowledge of facts, cannot be questioned, disputed or denied any more than the facts themselves. This authority is not conferred on them by vote, nor is it taken by force—it is theirs so long as it serves humanity in its quest for life and happiness. The problem therefore resolves itself into the mastering of time, or, in other words, the extension of human life and happiness into the future.

Yet even this aim alone is narrow and unsatisfactory. Mere "avoidance of starvation" appears today, in view of the advancement of science and technology, as an uninspiring daily toil. A higher ideal, a more inspiring aim of self-expression is instilled into the masses of even the most downtrodden people by the retrospect of the past struggle for mere animal existence. The desire to create can no longer be suppressed in the human masses. In factories as in politics it is no longer a full dinner pail that is the goal, but an indispensable means for self-expressive creation, for self-projection into the time to come. This philosophy, as established by Gantt, thus provides means and motives for accomplishing the natural aim of human development, and is bound to play the role of intrinsic leadership, pointing the way out of the welter into which the disregard of the fundamental law of humanity has brought us.



During the War the Critical Coal Situation was Similarly Studied by Government Agencies by Following the Path Blazed by Mr. Gantt. This Chart Shows Neglect to Use our Coal-Loading Capacity

At the solicitation of Mr. Polakov a number of discussions of his paper have been presented. It is not possible to publish these in their entirety, but the following selections from certain of them cover the main points which have been brought out.

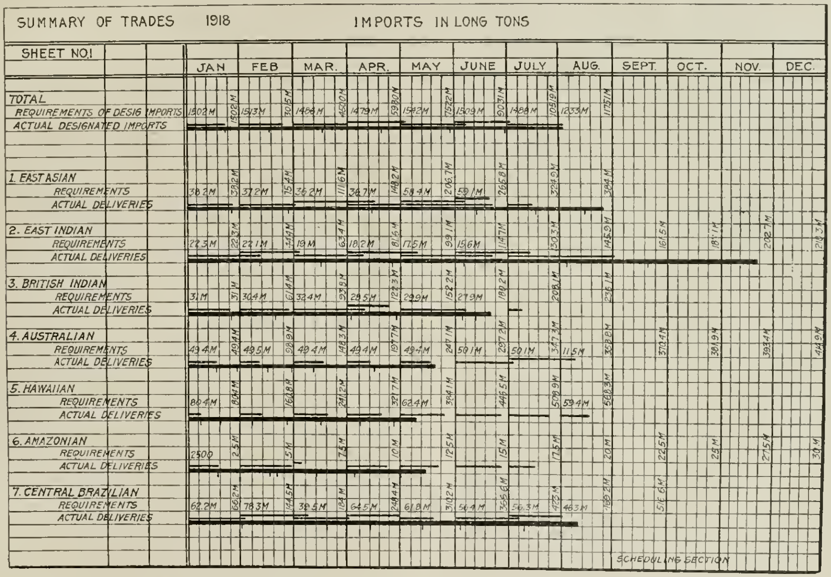
Robert B. Wolf. The faculty of recording past events as a guide to future actions is what Mr. Polakov claims to be the secret of the success of Mr. H. L. Gantt's method of recording plant progress by the chart method. These graphical charts make it possible for those in charge to be conscious of a greater portion of the *past* in the *present* than is the case with the old historical or descriptive methods, and it is because of this greater consciousness of past events that the future can be more definitely predetermined. This, of course, results in a maximum of production with a minimum outlay of *time*.

This concept, according to Mr. Polakov, was more specifically indicated by the Polish engineer, Alfred Korzybski, who brings out, for the first time, the outstanding difference between the three kingdoms of the organic world—the vegetable, the animal, and the human.

and the animal to "bind space," he next turned his attention to the records of human activities. He soon realized that the outstanding characteristic which distinguishes the human being from the animal is its capacity to record past experiments, to make them available for future generations.

All of the world's great religions were based upon the recorded teachings of their founders. Our whole system of law is based upon past precedents recorded in our court proceedings, and modern science is primarily an accurate history of the results of past happenings in the organic and inorganic worlds. It is this recording of events in *time* which is a distinctly human faculty and through it man becomes conscious of the operation of the principle of causation, for without this power of recalling past events man could not have come to a realization of the absolute unchangeableness of natural law.

This faculty of holding or fixing past events to make the knowledge of them a source of power for future generations, is what Korzybski calls "binding time." His third generalization is that man is therefore a "binding time" class of life. The natural effect of this is that each succeeding generation of mankind is able to begin approximately where the preceding one left off, whereas in the animal world each succeeding generation is obliged to begin practically where the preceding one began.



Foreign Trade May be Regulated by Gantt's Analysis as Well as Any Other Human Activity

It has been my privilege to review Count Korzybski's book and in order to discuss Mr. Polakov's paper intelligently it will be necessary briefly to explain Korzybski's expression "binding time" to which Mr. Polakov makes frequent reference.

Korzybski, who had ample opportunity to observe the destructive effects of commercial competition in Europe, concluded that human standards were but little above the animal standards and that the "survival of the fittest" naturally resulted. It was in the hope that he could find a fundamental distinction between the various classes of life that he began his researches by studying the accumulated records of the past.

He first turned his attention to the lowest form of organic life, the vegetable, and very soon found its main function to be the storing up of solar energy. The vegetable organism, which does not move about, but is attached to the earth, draws up through its roots the inorganic chemical substances from the earth and forms them into a cell in which the energy of the sun is confined. He therefore concluded that the function of the vegetable class of life is to "bind solar energy." Coal, for instance, is of vegetable origin and in burning it we release sun power.

He next directed his attention to the records of animal life and at once noted that the outstanding thing which distinguished it from the vegetable is its freedom to move about in space. As all life proceeds by multiplication, i. e., geometrical progression, each species of animal life was soon in conflict with every other species. This animal characteristic of movement *in* space and occupation *of* space resulted, of course, in a struggle for self-preservation. This was especially true in an environment which stimulated rapid reproduction of the species. Darwin observed this when he enunciated the principle of the "survival of the fittest"—no two physical bodies can occupy the same space at the same time.

These observations led Korzybski to his second generalization, namely, that because of this fundamental faculty of movement in space, the animal was destined to increase its power of movement by its occupation of more space. The animal, he therefore concluded, was a "binding space" class of life.

The far-reaching effects of this new realization of human life are expressed by Korzybski in his conception of what human competition *should be*, namely, *competition in time*—"survival of the fittest"—yes; but in *time*, not in *space*.

Man, therefore, by the basic law of his nature, is compelled to work for posterity. The animal is conscious of only one dimension of time, the present—man alone consciously uses all three: past, present and future. This is why real education, by means of the *true* presentation of the facts of the past, is the only cure for wars; also why humanity must resist any dogmatic attempt to keep the individual in ignorance. Safety lies only in a true evaluation of the past, in order that *present* humanity can consciously create a *future* which will be in harmony with the universal creative purpose.

My intense interest in the subject-matter of Mr. Polakov's paper is the amount of light that this concept of man as a "time binding" class of life throws upon my own past experience.

In Non-Financial Incentives[1] I showed how men invariably put forth their best efforts when furnished with continuous records of past performances. *In all such records the individual competes with his own past and with the past performances of others.* This is the secret of the baseball player's interest in the batting average, for it is only the animal that lives in the present, that competes with the present. Present competition is "space" competition, and therefore destructive.

Intelligent effort is creation, and as no such self-expression can be obtained without some degree, at least, of conscious use of past experience, it follows that this conscious use of time is the very essence of creation. It requires time to create a universe, a garden, or an automobile, and the production records of Gantt show clearly that it is only an efficient *use of time* that makes greatest productivity possible.

Gantt's conclusion that the Golden Rule is the most practical doctrine

[1] Presented at Annual Meeting of A.S.M.E., Dec. 3–8, 1918.

upon which to conduct business, makes an intellectual as well as an emotional appeal, looked at from the point of view of man as a "binding time" class of life, for it is only when every man does to every other man what he would have all men do to him that the human race can make its greatest progress in the *future*.

Judged by the same standard, that other great Christian injunction, "It is more blessed to give than to receive," is recognized to be the *only* practical guide to human life. Getting is "space binding" and therefore animal. Sooner or later our accumulations will conflict with those of others and a physical conflict is inevitable. We must cease our efforts to possess *things* and make *giving, which means rendering service*, our main object in life. In this way only can the human race attain a maximum of creative power, the possession of which insures an abundance of all "things" needed.

Alfred Korzybski. My tribute to the memory of Gantt will be not only the homage of a friend and admirer, but the proof that his philosophy is scientifically true. A rigorous proof is necessary, because the word "service" belongs to that category of words the meaning of which can be completely reversed by the verb, be it "give" or "take." Gantt took the "rendering of service" as an axiom; my observation.... was that our civilization had quite another axiom: "We preach give, we practice take." The problem which interested me was how to find a way out of this contradiction that would be irrefutable. If one of them is a true and natural law for humans, then the other is not; if our words are true, then our deeds are not true, or if our deeds are true then the words are camouflage. I found the solution by applying mathematically rigorous thinking.....

I defined the classes of life by emphasizing their incontestable dimensional characteristics; plants are "Chemistry-binding," animals are "Space binding," humans are "Time-binding" classes of life.

These definitions make it obvious, that:

1 The classes of life have different dimensions, and that as in mathematics the intermixing of dimensions makes a correct solution impossible, so in life the results of such elementary mistakes produce tragic consequences.

2 The old formula on which our civilization is built, Human equals Animal plus or multiplied by Spark of Divinity, is basically and elementarily wrong and is a mathematical nonsense identical with such an absurdity as X square inches equals Y linear inches plus or multiplied by Z cubic inches.

3 This basically wrong formula on which our civilization rests is the cause of all the periodical collapses, wars and revolutions.

4 The old system was built on animal "space-binding" standards, and human "time-binding" impulses were all the time in rebellion.

5 As the theory of gravitation and calculus made engineers and mathematicians masters of inanimate nature, so these tangible and incontestable definitions give them a positive base which will enable them to approach and solve human living problems by establishing the mathematical fact that man is man and not an animal ....

8 For the "time-binding class of life" it is obvious, then, that in this dimension "time binding" is the natural law, and, if analyzed and understood, is the highest human aim.

9 Such "natural laws" as "survival of the fittest" for animals, which is the "survival of the fittest in space," result in fight, or the survival of the strongest; whereas such a law, to be a *Natural Law* for humans, must be in the human dimension, which obviously would be the "*survival of the fittest in Time*," resulting in the survival of the best.....

11 All of our ideas have to be revised and the animal "space-binding" standards either rejected as dangerous and destructive, or transposed for "time-binding" standards which will correspond to the natural impulses and laws for humans.....

We are the masters of our own destinies; the responsibility is ours to correct the mistakes of our ancestors and to establish a scientific philosophy, scientifically true law, scientifically true ethics and a scientific sociology, which will form one unified science of man and his function in the universe.....

Gantt's concept of rendering service is scientifically true because it is "time-binding" and therefore true for the human dimension. This is why Gantt's concept has counted for so much, and will survive "*in Time*."

Charles W. Wood wrote that he had had many talks with Mr. Gantt and that he was in agreement with his facts and principles. Mr. Gantt, however, had to use phrases to express himself and one might disagree with a phrase. "Engineering," he said, "is an exact science, but English is not." A phrase used by Mr. Gantt and quoted by Mr. Polakov, to which he would take exception, was: "Reward commensurate with service."

Mr. Wood referred to numerous instances in industry, the school and the home where for the best interests of all the reward does not always go to the efficient, the brilliant or to the strong. For example, to whom should the teacher devote the more attention and, consequently, the greater portion of the public funds—to the bright child, or the dull one? We will all answer, "to the dull one." He needs more, and unless we give him more, things will go hard not only with him, but with the bright ones, too.

But if this principle doesn't work out in any of the other human relations, why do we try to apply it to industry? Doesn't it defeat the very aim which Mr. Gantt had in mind? Can we reach industrial coördination by trying first to establish absolute justice in the distribution of the product? One of his chief reasons for objecting to this phrase, Mr. Wood said, is that capital and labor both perform a service and there are so many loose-thinking efforts to find an equitable system of reward for each.

Isn't it more to the point to suggest rewarding both capital and labor according to their respective needs—which practically abolishes the whole concept of reward as we understand it today?

It is fairly easy, it would seem, to determine what a worker needs. He needs every possible encouragement to express himself to the limit in creative work: and to do this he needs to be freed from economic and social insecurity. Self-preservation and race-preservation are fundamental instincts, which must be attended to if one is to be set free for work worth while. Unless the worker can be certain of eating, and unless he is given a chance to love and mate and bring forth children, the workers will not be in a position to earn very much and our whole industrial organization may be destroyed by the pangs of hunger and sex.

And isn't it easy, also, to discover what capital needs? Capital likewise needs perfect functioning: and if it is allowed to function perfectly it will cause no trouble. Capital, in fact, is an inanimate thing which can be perfectly controlled by engineering; and it should be easier to discover its exact needs than to ascertain what the normal requirements of the living workers are.

There is, Mr. Wood admitted, another factor in our present industrial order, which is not so easily disposed of. It is not living labor. It is not inanimate capital. It is a group of living persons known as owners. Some of them perform service. Some of them do not. How are we to reward them? According to the service they personally render, or according to the service their capital performs? And if we pay them for what their capital does, how can we reward the *capital* commensurately? It might be that they would not put this reward back into necessary reinvestments but spend some of the money upon themselves. That would not be "reward commensurate with service." It would not be paying the capitalist for what he does but for what he owns.

Once again, isn't it the scientific solution to consider not what the capitalist does, nor what he owes, but what he needs? He is human and he needs what every human being needs—a chance to function perfectly as a creative human being. If he is capable of rendering service, should he not be equipped to render all he can?

It would seem that Mr. Gantt did answer many of these questions and that his work must lead us to a clearer conception of industry as an agency for the supplying of human needs rather than a scheme for the gratifying of inhuman greed. Instead of seeking to establish rewards commensurate with service, are we not seeking to establish service commensurate with human possibilities? And does not the establishment of such service bring with it all that the human heart can wish?

Hugh Archibald contributed a discussion in which he drew on his experience in the coal-mining industry to illuminate the principles developed by the author.

Some years ago he was telegraphed for to rescue a mine from being drowned out; the pumps would not work. He found a new boiler plant with water-tube boilers equipped with Dutch ovens, rated at 1500 hp., and about a thousand horsepower of engines altogether in which to use the steam. But there was no insulation on the steam lines and the weather was near zero. There was one line 2000 ft. long which was leaking at every joint; there were no steam traps before the engines; there was no valve between the old boiler plant and the new and steam was condensing in the cold old boilers. Steam, even, was pouring through an old steam-jet blower, making a forced draft up a cold chimney. No wonder that the forcing of the boilers would not run engines and pumps!

Around the mines the industrial structure was working about as well as that steam plant. It needs to be made over and in doing so fundamental laws need to be known. There are leaks to be stopped, insulation to be applied, and steam traps to be installed.

Mr. Polakov has pointed out three elements of "rendering rigorous service," said Mr. Archibald. The first of these is that reward should be commensurate with service rendered. No wage payments which would conform to this rule exist in the coal mines. For instance, mine foremen, who by law are in charge of all inside workings and who may have under them from one hundred to five hundred employees, are paid about a dollar an hour, while the diggers of coal are paid at the rate of two to three dollars an hour. The mine foreman does not suffer from intermittent employment or from "unemployment within employment," as the digger of coal does, so that at the end of the year his earnings are more than the man he employs. The digger of coal, on the other hand, suffers so much unemployment that he has to be rewarded, in part at least, for the time during which no service is rendered.

The second point which Mr. Polakov makes for rendering rigorous service, is the elimination of idleness before securing additional means of production. The intermittency of operation of coal mines has become common knowledge. Almost every one knows that bituminous coal mines operate on an average about 230 days in a year and that not even anthracite mines are in service continuously. There is a great overdevelopment of coal mines and yet more are being opened every day.

A third point for service is the "utilization of available knowledge without awaiting new discoveries." It is safe to say that if engineering work such as H. L. Gantt did in manufacturing were done in and around coal mines, the output of the mines on the days when they were operating would be increased fifty per cent and the cost of mining coal reduced.

Back of all these points is the fundamental law that the purpose of human life is to "bind time," which has been stated by A. Korzybski and to which Mr. Polakov calls attention.

If disregard of fundamental laws produces machinery which will not work, the same disregard will produce social structures which will not work. And if "binding time" is one of the human purposes (and it surely is), then coal mining is violating that law and the coal industry needs redesigning. For as it is now operated, it does not bind time but captures idleness.

We need to know fundamental laws that engineers may design structures which others can operate. Mr. Polakov's paper has contributed to the possibility of a better design.

Locomotives and Locomotive Terminals

Salient Points Brought Out in Discussion of Papers on Increasing the Capacity of Old Locomotives and Modernizing Locomotive Terminals, Presented at Railroad Session of A.S.M.E. 1920 Annual Meeting

Two important papers presented at the Railroad Session of the Annual Meeting of The American Society of Mechanical Engineers were those entitled Increasing the Capacity of Old Locomotives, by C. B. Smith,[1] and Modernizing Locomotive Terminals, by G. W. Rink.[2] Mr. Smith discussed the problem of providing adequate facilities for keeping old locomotives in service and adapting them to new demands of suburban and local service, emphasizing the need of making provisions for carrying out a program of reconstruction and improvement. The paper by Mr. Rink dealt with the question of providing adequate facilities for the proper maintenance of locomotives at engine terminals, which has an important bearing on the ability of the railroads to handle the increased traffic demands of the country. Abstracts of these papers were published in the January issue of Mechanical Engineering. The papers brought forth considerable discussion, the most important points of which are presented in the following extracts.

Increasing the Capacity of Old Locomotives

P. M. Hammett.[3] Programs for the application of improvements to locomotives should be carefully studied by each railroad in the light of its own traffic conditions, as no general conclusion is justified. On roads thoroughly constructed and well maintained, new locomotives may be of greater weight and power than can be obtained by the reconstruction of old engines and should be preferred in so far as their greater ability can be continuously utilized. Where conditions do not permit large increase in weight, improved devices should be applied to existing locomotives of such type and age as have further profitable service life of ten or more years.

Roads having main lines or branches where light traffic does not call for maximum performance should be cautious in the application of devices of expensive character to locomotives for such service.

Shop plants on many railroads are inadequate in quantity and capacity to the needs of normal maintenance. In such cases the application of improvements to existing locomotives has been limited rather by shop capacity than by restriction of appropriations. Those improved devices receive most rapid acceptance which impose less burden on railroad shops, either by their nature or by reason of general engineering development and complete manufacture of material by those promoting and offering them to the railroads. Any extensive program for improvement of locomotives should include as an essential part, a study of the period which may profitably be allowed for its execution, and provision of facilities sufficient for its execution within that period.

J. C. Hassett.[1] An improvement policy was inaugurated on an eastern road in 1910 and 1911 and the first superheater locomotive with piston valves was completed in April 1912. To date 160 locomotives have been so converted, representing an average annual production of 20 locomotives. The fuel saving per locomotive per year varies from $2000 to $3000 at present prices for coal. This has been done without any retarding effect on the output of locomotives regularly scheduled through shops and without any drastic revisions or increase of shop forces.

Experience in applying superheaters to locomotives, applying piston valves, outside valve gears, etc., shows the cost to be about $8500, covering betterment, renewal and overhead charges, as compared to $40,000, the cost of a new locomotive at the time the modernizing was done.

Another phase of this superheating problem is the retention of the old slide-valve cylinders and Stephenson valve gear through the application of a piston-valve type of steam chest. One locomotive was so equipped about six years ago and has been giving continous and satisfactory service since. This application can be made for approximately $1800 less than the amount required to add new cylinders and outside valve gear.

In reference to the weaknesses of the main frames of locomotives built during the past ten years, alluded to by the author, probably no road has been immune. A certain group of 52 locomotives of the 4-6-0 type was built in various lots during 1904, 1906 and 1907. These 52 locomotives sustained 30 per cent of the total frame failures of approximately 1250 locomotives on the road.

In the final analysis of this serious situation it was found that the frame sections were, and had always been, too small, based on the areas of sections established by best engineering principles. In the preparation of the new design, the sections were increased.

Locomotives are receiving heavier frames at an approximate cost of $3500 per locomotive, including additional cross-ties, boiler supports, etc. The performance of these locomotives to date has been very creditable.

The extent to which application of heavier frames of proper size can be made to old locomotives will be in large measure limited by the increased weight which can be placed on axles, bearings, spring riggings, etc., without renewal of these parts.

H. B. Oatley.[2] The writer desires to bring out the features which have prompted the very extensive superheating programs which have been in vogue on many of the railroads for a considerable period. The table accompanying this discussion gives

COMPARISON OF SATURATED AND SUPERHEATED-STEAM LOCOMOTIVES OF VARIOUS TYPES

some comparisons between saturated and superheated locomotives of some of the types mentioned by the author.

By the addition of a high-degree superheater it has been demonstrated that the steam consumption per horsepower-hour is reduced about 28 per cent. The figures commonly accepted as representing good practice are 27 lb. for saturated steam and 19.5 lb. for superheated steam. It will be noted that in the case of the 0-6-0 type boiler the horsepower has been increased 15 per cent; for the 4-4-0 type 14 per cent; for the 2-6-0 type 13 per cent, for the 2-8-0 type 10 per cent, and for the 4-4-2 type 10.2 per cent.

The maximum cylinder horsepower, using the American Locomotive Co.'s figures, has, by the addition of a superheater, been increased about 8 per cent.

When considering existing locomotives the increase in the maximum tractive power requires consideration of (1) the factor of adhesion, and (2) the strength of the running gear, which has to withstand the thrust of the piston.

As in all other problems, the cost of making improvements must be balanced against the advantages which can be realized.

W. O. Moody.[1] Where a program involves the modernizing of a large number of locomotives, it necessarily follows that the work must extend over a period of years, which time may be extended due to market conditions, as an inflated price situation may make it advisable temporarily to suspend the work.

Water and fuel conditions in different localities may be governing factors in determining the policy of reconstruction, so that what would answer all requirements to a class of power in one section would not guarantee equally favorable results elsewhere.

To do this work under a well-studied program on any extensive scale will call for increased shop facilities either in space or old tools replaced by modern, so that the old shop is also modernized to be in harmony with its new output.

By purchasing many of these devices, on the open market, machined and assembled, the back shop is relieved of a fair percentage of the burden of manufacture.

Outside valve gears can be purchased and applied without a very great increase in shop work over a link motion, which may require renewal of a large number of parts.

It would be well to send to each of the larger roads a questionnaire prepared with a view to bringing out their program, with list of engines modernized to date, and those remaining, to furnish a general idea of the extent to which this work is being done.

We also have another factor which determines the reconstruction program. A road may have a satisfactory class of saturated engines, which on later orders have been equipped with superheaters and larger cylinders, so that it is a wise policy to have the superheated type serve as models when reconstructing the saturated ones and thus reduce class, and likewise the storehouse stock and patterns.

Some prominence is being given to one feature not mentioned among the author's eighteen items of improvement: namely, the booster which apparently has a wide field of application to either freight or passenger power, depending somewhat on local conditions for the most favorable results.

E. A. Averill[2] gave as an example of what can be accomplished on even some of the more modern locomotives built within the last six or eight years, results recently obtained from road tests on locomotives equipped with feedwater heaters. Tests were made on three different railroads and showed an average of $237 saved in fuel cost per month per locomotive.

Feedwater heaters which will raise the temperature of the water from 40 or 50 deg. to from 230 to 250 deg. have been in successful railroad service for over three years. These heaters filter all the water formed from the condensed exhaust steam and return it, free from oil, to the tender. This adds about 14 per cent to the capacity of the tender and greatly extends the distance that can be made between stops for water.

On most locomotives an increased boiler capacity can be fully used in regular service, and furthermore, since any boiler is most economical and most efficient at its lower rates of working, an appliance which makes the boiler larger always shows returns.

J. T. Anthony.[1] Of 65,000 locomotives in service on American railroads, only 35,000 are equipped with superheaters, 43,000 with arches, 37,000 with automatic fire doors, 15,000 with power reverse gears, 2000 with automatic driving-box wedges, and only 30 with feedwater heaters, to mention only a few of the items listed by the author.

The brick arch can be installed in the roundhouse in less than 24 hours, and to use a conservative figure, is good for an average reduction in fuel consumption of 10 per cent, or an increase in boiler capacity of 11 per cent.

There is probably a wide diversity of opinion as to the relative merits of the 18 items given by the author as desirable improvements and there are several other items that could be added to a program for the rehabilitating of old locomotives, such as the booster, radial buffer, automatic grate shaker, and thermic siphon. Perhaps the author had the latter device in mind when he mentioned improved circulation and increased firebox heating surface.

There are only three methods of increasing the heating surface of an existing firebox, i.e., by the installation of combustion chamber, the installation of arch tubes, or thermic siphons. At the present time there are only 6000 locomotives equipped with combustion chambers, and something over 100 equipped with thermic siphons, this device being of rather recent origin.

Frank McNanamee[2] said that he concurred with the first two statements of the author's paper, but that the second did not go far enough. In other words, he said, it was not enough to modernize existing locomotive equipment by adding new locomotives to it or by rebuilding old types. The new locomotives and the modern devices with which the rebuilt ones were equipped must be maintained. Superheaters, brick arches, mechanical stokers, feedwater heaters and other modern devices mentioned by the author must be properly maintained to be effective. The modernizing of locomotive terminals and the provision of an organization to maintain the improved devices is a third method.

G. W. Rink said that the conditions of the C.R.R. of N.J. were similar to those mentioned by the author, there being a heavy suburban traffic which required the services of all the locomotives owned by the road. A constructive program was under way for modernizing the locomotives by the application of various devices. The program consisted, he said, in the application of superheaters and cylinders, thus increasing the tractive power of suburban locomotives so that they could haul 11 or 12 steel coaches rather than nine as previously. A number of tender frames had been changed, enlarging the capacity from 5000 to 7500 gal. Outside valve gears were also being applied to heavy consolidation locomotives equipped with Stephenson motion.

Modernizing Locomotive Terminals

William Elmer[3] presented a discussion of this paper to show that much could be accomplished by closer supervision of existing terminals through a system of daily reports. He said the greatest effort should be made to get the maximum possible mileage and service out of the engines and that the first thing to do is to impress everybody with the value of an engine-hour. In support of this he noted the following instance:

On one of the divisions of the Pennsylvania Railroad the freight earnings were $4,000,000 in a recent month. The average number of serviceable freight locomotives was 78 and they were on the road 52 per cent of the time. As there were 720 hr. in the month this is the equivalent of an average of 41 engines working constantly, or 29,500 locomotive-hours. As they earned $4,000,000 each engine-hour was worth $137. Now if every man connected with the motive-power department could be made to realize that an engine is worth from $100 to $200 an hour, he believed we should see a great improvement in the pace of everybody around a locomotive terminal, from the hostler to the foreman.

Mr. Elmer described fully how by means of complete daily statistics of the engines under and awaiting repairs at the various

called upon in an emergency are fundamental. In arranging the tracks and various terminal facilities, it must be borne in mind that if the best operating results are to be obtained, the terminal should be planned to restore power to service in the shortest possible time.

Serious consideration is now being given by the motive-power departments of several roads to the use of more small back shops and fewer general-system shops. This seems to work itself out best, unless the number of locomotives turned is quite small, by having these back shops located at every other terminal; that is, the intermediate terminal simply serves for turn-back purposes and handling light running repairs. It has been found that the efficiency obtained from large aggregations of labor and tools is lower than from smaller units, where more intense supervision is possible. Furthermore, smaller units simplify the labor problem and tend to maintain a continuity of repair service in case of local labor difficulties. Finally, a larger number of shops reduce materially the dead mileage of locomotives between the terminal where they are released and the shops where they are repaired.

Serious mistakes have been made recently in connection with some recently built terminals in selecting their location without giving proper consideration to the labor side of the question. It is more economical to pay more for terminal property if this is necessary in order to insure a constant supply of labor.

Drainage is another factor to consider in locating a terminal, bearing in mind that the turntable pit, drop pits, and pits under the track hopper at the coaling station are the controlling points.

No terminal track layout is complete without separate tracks for inbound and outbound movements and at least four tracks leading to and from the turntable. It should also be so arranged that locomotives may receive coal, water and sand inbound or outbound.

The test of terminal facilities is their ability to function in zero weather. While a terminal may function readily under normal traffic and weather conditions, it cannot be considered adequate if it fails under unusual conditions. At a terminal handling 170 locomotives in 24 hours the writer recently found 15 locomotives waiting at the ashpits to have their fires cleaned. Two improvements were necessary to relieve this situation: more tracks over the ashpit and greater ash storage capacity, as the pits were of the shallow-water type located between the rails. It will be seen that if this delay occurred every day and averaged 30 min. per locomotive, the capitalized earning power of the locomotives would more than finance the entire cost of a terminal of this kind.

Roundhouse and Shop. The author makes only passing reference to the type of roundhouse to be used. Generally speaking, the writer believes that all roundhouses should be of fireproof construction and that terminals handling 75 locomotives and up should be provided with bridge cranes, or at least jib cranes at each stall. Recent experience seems to show that it is a mistake to provide only a bridge crane in a roundhouse, as the demand for service is more than one crane can supply. Therefore it is probably better to provide jibs at each stall in addition to a bridge crane and use the jibs for the lighter work.

Light-Repair Shed. A development which seems to have real possibilities has been put in practice on several roads and takes the form of a light-repair shed. Locomotives requiring the minimum of attention from the repair force are put through this shed, which may be located near the roundhouse, where it can be under the supervision of an assistant to the roundhouse foreman, and convenient to the storehouse and machine shop.

Coaling Stations and Sand Storage. The writer believes that the question of coal-storage capacity at terminals has not received sufficient attention. Coal in the bins sufficient for a 24- or 48-

[1] The H. K. Ferguson Company, Cleveland, Ohio.

be such that sand can be protected from the rain and snow.

Ash Handling. In districts where the winters are severe, the location of the ashpits with relation to the enginehouse is important. The distance should not exceed 1000 ft. and should preferably be about 700 ft. from the house. The purpose of this is to prevent the detrimental action of cold air on the flues and permit the uninterrupted movement of the engine to the house.

In considering the type of ashpits to be used, time should be the controlling factor. It can be shown, for instance, that the depressed-type pit is cheaper to operate than a water-type pit, particularly when the fixed charges of both are considered; but the reliability of the water type under all weather and labor conditions is what has convinced many roads of its superiority over other types.
